INTRODUCTORY LECTURE  
TO A  
COURSE ON PRACTICE OF PHYSIC,  
DELIVERED AT  
MINTO HOUSE,\* ARGYLE-SQUARE, EDINBURGH.  
By GEORGE W. BALFOUR, M.D., F.R.C.P.

MODERN THEORIES OF INFLAMMATION.

GENTLEMEN,—There is no subject more deserving the attention of the physician than that of inflammation—a process which, without attempting more accurately to define its frequency, we are safe in saying, underlies by far the larger proportion of those ailments to which the human frame is liable, besides complicating dangerously or otherwise a very considerable number of those cases of disease not actually originated by it. There is no wonder, then, that the nature of the inflammatory process has formed a subject of most anxious inquiry and of eager speculation to medical men in all ages, and the importance of this inquiry and of these speculations, in relation to the well-being of mankind, may be readily estimated by the influence which they have exerted upon medical practice, the treatment of disease having been based to a large extent upon the prevalent theory in regard to the mode of origin, course, and termination of inflammation. It is needless to occupy your time at present by recapitulating the theories of Hippocrates, Galen, and Celsus, of Pythagoras, Chrysippus, and Erasistratus, of Van Helmont, Boerhaave, Hoffman, and Stahl, or even of one so recent as Cullen, the influence of whose teaching has not yet wholly disappeared from our schools. Some of the theoretical queries of these eminent men have been confirmed, but most of them have been overthrown. Not only are many diseases now regarded as inflammation, or as the results of inflammation, to which they would have denied that term, or scorned to ascribe to any such cause, but the very essence of the process is now viewed in such a totally different light from what it was by them, that one of the most distinguished of modern pathologists has likened the term inflammation to a coin without a mint stamp, which ought to be cast aside as only liable to produce error and confusion. The term inflammation is, however, too deeply imprinted in the history of our art to be ever cast aside, and though it be no longer restricted to those diseases in which the parts affected seem to burn or be on fire, and though the *Quatuor Note* of Celsus are now-a-days insufficient for its diagnosis, it is not because those diseases or these *Note* do not represent inflammation as now understood, but because the light of modern science and of modern pathological investigation has revealed the fact that these characteristic phenomena, even where persistent, are not always accompanied by those structural changes which from time immemorial have been regarded as the results of inflammation, and are not, therefore, always signs of inflammation, while it has also taught us that there are many morbid affections unattended by those phenomena which are yet followed by these structural changes, and to which, therefore, we cannot refuse to apply the term inflammation. Thus far from introducing confusion into our ideas of the meaning of this term, modern science has done good work in giving them precision, and in enabling us, in making our diagnosis, to correct the evidence of our senses by the efforts of our reason.

It has not effaced the stamp from this ancient coin, but

has renovated the legend and given it a distinctness which cannot fail to enhance its value both now and in future ages. During this process of renovation our ideas of the essence of the inflammatory process and of the nature of its stages have undergone several changes, and though it seems probable that we are now in the right way of arriving at the truth, it cannot be said that we have as yet attained it, because it is unquestionable that many of our present notions are destined to be remodelled when we attain more accurate ideas of the nature of the anatomical elements involved.\*

All our modern theories of inflammation date from the employment of the microscope in pathological investigation, and those of most importance are altogether of recent origin. They are based upon two distinct sets of observations, which cannot be connected, except by a process of ratiocination; and all the discrepancies which exist in our ideas of the process of inflammation arise from the different values ascribed to the facts upon which our reasonings are based. The one set of observations has been made upon the early or initiatory stages of inflammation, as seen when artificially induced in the transparent parts of animals; while the other set has been made upon those structural changes which are universally acknowledged to be the result of inflammation; the connecting links between the two being lost in that universal haze which obscures the most transparent parts so soon as the inflammation has reached a certain height. It is these links which it is the province of our reason to supply, and it is in supplying these that the greatest discrepancies of our modern theories have arisen. Thus we cease to be able to see the inflammatory changes taking place in the transparent tissues of the frog or any other similar animal just at that most interesting point when those tissues become obscured by what seems to be the escape of fluid (exudation) from the vessels into their substance, and the thread of the discourse cannot be again taken up till we meet with the developed results of inflammation upon the surface, or in the organs or cavities of those animals who have suffered from it. And it was a very simple generalisation which led to the supposition that these results were merely the effect of the continuous development of the fluid exudation, its molecular matter being gradually aggravated into granules, nuclei, and cells, which subsequently became ripened into pus or developed into cellular adhesions, the natural tissues of the body remaining passive during the process. Could we have seen this exudation passing through these different processes all doubt as to the truth of this generalisation would have been at once removed, but as this is impossible, these doubts exist, and they are confirmed and strengthened by the fact that there are many cases of undoubted inflammation in which there is no exudation whatever, and in which the cloudy swelling depends solely upon the abnormal nutrition of the elements of the natural tissues of the body themselves, leading to the possibility of a still higher and simpler generalisation, that inasmuch as disease and inflammation as one form of it is no new force or entity, but simply "the product of the body itself—that is, of the vital actions always taking place within it," so its results are not the consequence of the development within the body by a *generatio equivoca* of any novel tissues, but are simply the product of the natural tissues of the body itself altered in their development by the nature of the pabulum by which they are nourished, and the change in the vital conditions by which they are surrounded and influenced.

In the further consideration at present of the theories of inflammation, I shall first describe what has been actually observed to follow the application of an irritant to

\* Minto House was in former days the town residence of the earls of that ilk; it subsequently was the home of the late Dr. Andrew Duncan, becoming afterwards a private surgical hospital (under the care of Professor Syme). The readers of "Rab and his Friends" will be interested to learn that old Ailie died in an apartment now occupied as a chemical laboratory by Dr. Crum Brown, for that pathetic tale is no fiction, and over its paths to the sadness of reality more even than to the gifted intellect of its author.

\* Particularly in regard to the canaliculi apparently connected with the connective tissue cells, which some think, and I believe Virchow himself now takes this view, are a separate circulatory system wholly unconnected with those cells. While the doctrines in regard to the protoplasmata now beginning to be promulgated, promise in no long time to revolutionise our ideas.

the transparent parts of animals; I shall next detail the ordinary results of inflammation, and describe the reasonings which have been employed in the explanation of the etiology of these results, as well as of the ordinary termination of inflammation. On the application of an irritant, such as a drop of alcohol to the web of the foot of a young frog, the blood at first flows more rapidly than naturally through the capillaries, then sways to and fro, and finally ceases to circulate—the capillaries becoming densely congested or filled with these stagnating corpuscles, some of which occasionally escape through rupture of the vascular walls, while the intra-vascular spaces of the web become thickened, clouded, and more or less opaque, partly by the action of the alcohol, and partly by the effusion of the liquid plasma—this opacity first occurring in the neighbourhood of the vessels and subsequently spreading through the whole intra-vascular space—the opacity thus induced precluding further observations. Such are the phenomena ordinarily observed on the application of an irritant to the transparent parts of animals; but the mere observation of these phenomena gives us no clue to the etiology of inflammation; to attain any true idea of that we must endeavour to obtain correct notions as to the causation of each separate step in the sequence, and in order to attain this we must first ascertain the anatomical structure of the tissues concerned. The most important of these are, of course, the capillaries and smaller arteries; both we know to be extensible, but after a different fashion. For the capillaries are formed by only one delicate homogeneous membrane, beset here and there by nuclei, elastic but not contractile, incapable, therefore, of complete closure, but presenting divers variations in their calibre explicable by the differences in the distending force of the current of blood. While the minute arteries, on the other hand, some of them much less in size than average capillaries, are all possessed of three coats—viz., an external layer of cellular tissue in variable quantity, a delicate internal membrane, and an intermediate circular coat, consisting of a single layer of muscular fibre cells, wound spirally round the internal membrane. The capillaries, therefore, are from their structure, elastic, but non-contractile, while the arteries even in their minutest subdivisions are highly contractile, and may be constricted even to absolute closure. When this constriction is extensive, the blood moves very slowly through these arteries, and when it is complete, they, as well as the capillaries and veins, become so apparently exsanguine as to be with difficulty distinguished from each other, and the web of the frog's foot appears as if it possessed no blood-vessels at all, presenting an appearance precisely similar to the death-like pallor of the human cheek in syncope, or to the dead whiteness of the human fingers when benumbed with cold. This is that spasm of the extreme arteries so much insisted on theoretically by Cullen as the initiatory stage of inflammation, and which has been actually observed as such, both by Lister and Wharton Jones, while its causation is unquestionably due to the reflex action of the nervous system, an action first insisted on by Whytt, Hoffman, and Stahl, and has in recent days been illustrated in a very interesting manner by a curious experiment, first performed by Drs. Brown-Sequard and Tholozan. These gentlemen found that on plunging one hand into ice-cold water, the other fell in temperature—in one case so much as 22° F., but generally from 6° to 8°—and this did not arise from any diminution of the general temperature of the body, because that, as measured by the temperature of the mouth, was never lowered more than 1°, and when the loss of temperature of the hand not plunged into water was greatest, it actually did not amount to more than one-fifth of a degree. But it is *a priori* evident that the chilling of the hand kept in the air must depend upon one of two causes—either the arrival in it of a cooler blood, or the diminution of the amount of blood naturally distributed to it. The first supposition is, however, excluded by the fact just alluded to, that the temperature of

the general mass of the blood is very little, if at all, reduced, and we are therefore forced to conclude that the amount of blood sent to the hand is diminished, while as the heart continues to send perceptibly the same amount of blood, we are irresistibly led to conclude that the blood-vessels in the hand are anomalously contracted by the reflex influence of the nervous system, there being no other mode in which that action can be produced, and the efficacy of this being capable of still further, and more exact, illustration by various experiments upon the nervous system, into the details of which we have not at present time to enter. This reflex contraction of the arteries is sometimes so great that not a single drop of blood escapes from their divided extremities, and the power of producing it through the nervous system is largely made use of in the treatment of certain forms of hæmorrhage; its influence in the production of inflammation I shall point out presently, when I have said a few words as to the state of the blood as observed when circulating in inflamed parts. But first, I must say that this state of pallor and bloodlessness of the parts, though it may be and often is the precursor of inflammation, is yet not inflammation any more than is the fullest dilatation of the arteries and capillaries which may succeed this condition, or may be directly produced by section of the sympathetic, which, though attended by the passage of a much larger amount of blood than natural, by increased rapidity of nutrition, and a greatly increased development of heat, is yet unattended by any strictly morbid phenomena. When, however, this constriction of the arteries has been maintained for some time, or has been repeatedly brought about at short intervals on the same spot, other phenomena begin to show themselves. The liquor sanguinis still passes on freely, but the corpuscles lay behind; they adhere to one another, and their motion being thus obstructed, while the vis a tergo continues acting, they cram the dilated capillaries with a mass of adhering corpuscles oscillating to and fro, and moving slowly onward, apparently as impelled by the heart's action, and when they finally reach the veins or some healthy anastomosing capillary, they pass into them in the form of broken clumps or masses, which sometimes project into these vessels, and move to and fro in the current of healthy blood for a few moments before they are swept away in its torrent, within which this peculiar adhesive tendency speedily disappears. This stage is termed that of inflammatory congestion or stasis; and the peculiar tendency of the blood corpuscles to aggregate together and adhere to one another constitutes no unimportant element in its causation, constituting, moreover, a practical illustration of that lentor or visciditas of the blood, which Boerhaave supposed to be the cause of inflammation, but which is really only one of its stages, and of purely local—not of general origin, as he supposed. The production of this peculiar condition of the blood corpuscles is supposed by one set of observers to depend upon an increased mutual attraction between them and the surrounding parenchyma; but this is denied by another set, who very properly point out that this adhesion of the blood corpuscles can hardly be regarded as a vital property, inasmuch as while it is never seen in the normal condition of healthy blood, it is not only instantaneously developed when a drop of blood is brought into contact with inert or dead matter, as when it is shed upon a piece of glass, the blood running instantly into rouleaux, formed by the discs adhering to one another by their flat surfaces, in net-work fashion, but also continues to present itself for a long period even after all the fibrine has been removed, and the blood corpuscles have been pickled in gum. In one such case this peculiar property was observed so long as twenty-four days after the blood had been separated from the body; but properties formed by blood corpuscles so long removed from the body, and so altered in appearance by the gum can hardly be imagined to be vital. Unquestionably, however, as is shown by other experiments, very slight changes in the chemical condition of the plasma in regard to visciditas, &c., are capable of apparently influencing the production of this peculiar adhesiveness, but it is

equally unquestionable that the great change which takes place in inflammation consists primarily in the abolition of the relations normally subsisting between the blood and the tissues, in which condition the blood in the vicinity of the disabled tissues assumes the same character as when in contact with ordinary solid, dead, or inert matter, and thus becomes unfit for transmission through the vessels. This peculiar effect upon the tissues may be produced directly or indirectly through the nervous system. In the latter way—indeed frequently in the former, but always in the latter—the first effect is the production of a constriction of the arteries which prevents more or less completely the circulation of the blood through the part, throwing the tissues affected therefore into a state more or less akin to molecular death, which may however be, if not too long continued, perfectly recovered from without any ulterior results taking place; and when this recovery takes place under the influence of treatment, this is what is termed cutting short an inflammation, though more correctly speaking it only checks the process which would lead to an inflammation, or the tendency to it. We see then that in this view of the nature of inflammation it is simply a healthy action following an injury done to some tissue or organ, directly or reflexly; it is the natural and vital reaction of the organism to an injury received; it is, as has been well said by Mr. Hinton, the restoration of a life that has been lost; it adds to vitality, nor detracts from it; loss of vitality is its starting-point, but not its essence. This idea of the nature of inflammation is essentially solidism, as opposed to the doctrines of humoralism, which imagined a quantity of peccant matter—in this case the fibrine—to be accumulated in the blood and to become deposited upon or into certain organs, on the principle of rubbish shot here. But it is essentially a vitalistic or dynamical solidism. Beyond this point—that of stasis, or complete congestion, it is impossible to follow the process of inflammation any longer with the eye. Even the most transparent tissues become opaque and obscure, by the transudation of the liquor sanguinis more or less deeply coloured by the partial escape from the blood corpuscles of the red colouring matter. Occasionally the vessels burst and extravasation of the blood corpuscles takes place through the rupture, and the theory of inflammation as a morbid process is from this point onwards simply a mass of more or less plausible conjectures.

To bring it even so far many years of careful observation have been required, and much thought has had to be expended in the connection of these observations. As an apt, and in many respects a most interesting illustration of this, I may refer to what Kaltenbrunner, one of the earliest microscopical observers, fancied he had seen in relation to the black pigment contained in those stellate cells which dot the surface of the frog. He fancied that direct absorption of the natural tissues formed part of the inflammatory process, and supposed himself to have been lucky enough to catch the exact moment when the torrent of the circulation had detached a particle of colouring matter from one of these stellate rays and carried it away, and this he thought was an example of the mode in which these stellate rays become reduced to mere scattered black specks. More careful and accurate observation has taught us now that the pigment in these cells is not thus removed, that in fact it is not removed at all. Like every other part of the body, these pigment cells and their contents are under nervous influence; any irritation or excitement causes the pigment to concentrate round the central nucleus, leaving the skin pale and dotted with black points, but when the irritation is sufficient to produce nervous paralysis, the pigment remains unconcentrated in its original stellate form. The apparent disappearance of the pigment from the rays of the stellate cells is not therefore caused by absorption and removal by the blood, but is the result of concentration caused by the same nervous action which produces the contraction of the smaller arteries with which it is coetaneous, while the arterial relaxation and simultaneous

vascular congestion is accompanied by a diffusion of the pigment in the cells, both being caused by the cessation of nervous action. These peculiar motions of the pigmentary granules, therefore, besides being a measure of the accuracy of modern observation, are also a further proof of the importance and far-reaching character of nervous action, and the history of their discovery furnishes an excellent illustration of the necessity of basing our reasonings regarding any process not upon partial and limited observations restricted to one form of tissue, or anatomical element, but as far as possible upon all which are within the same sphere of vision, observations made on one tissue being capable of connecting or strengthening the opinions formed from observation made upon some other. Inflammation, then, so far as it can be seen, consists in a precursory stage in which the smaller arteries are so greatly constricted that the part is often rendered wholly exsanguine; in man it is probable that this stage is coetaneous with the primary rigors. This stage is wholly unattended by any alteration in the condition of the blood corpuscles, the vital properties of the tissues still remaining unaltered. The second stage is attended by a dilatation of the arteries and capillaries, which are crowded with blood corpuscles still rolling over one another freely, and behaving as in health. This is the stage of reaction; and the third stage, that of stasis or congestion, which some call the first of inflammation, is evinced by a close aggregation and adherence of the blood corpuscles to one another, the aggregated mass passing onwards with difficulty into the veins or healthy anastomosing vessels. This stage is only produced by long continuance, by repeated application, or by relative severity of the exciting cause, and is characterised by a behaviour of the blood corpuscles precisely similar to that which they present when effused from the body or surrounded by dead and inert matter. Observers, we have seen, are now-a-days tolerably well agreed as to those facts, though, as I have already shown, they differ materially as to their explanation, and the case is no otherwise in regard to the results of inflammation. To spare time I shall confine your attention for the present to three acknowledged results of inflammation—results in which we take up anew the leading clue of our theory, the intermediate steps being lost in obscurity, as I have already pointed out. The three results to which I shall at present confine your attention are—fibrinous exudation, suppuration, and ulceration. No one doubts the existence of these results as the consequence of inflammation; the means by which they are attained is still, however, a matter of dispute. The more ancient theory supposes that the exudation of the liquor sanguinis is caused by a morbidly increased attraction of the tissues for it. This exudation is then supposed to coagulate, and that it then passes through various transformations which are supposed to favour its escape from the body or its development into certain morbid tissues, these transformations being produced within itself, the exudation when it lives constituting a molecular blastema, within which, by the aggregation of molecular matter, cells and fibres are formed, according to the nature of the exudation. When suppuration takes place, these molecules aggregate into cells, which gradually develop into pus cells, these when ripe falling to pieces, and being either removed by absorption or otherwise escaping from the body. This theory of inflammation regards it as in its essence and in its entire course essentially a morbid process, the exudation taking place by means of a morbid and abnormal attraction, and then becoming developed in various ways by a *generatio equivoca* of cells and fibres which develop themselves out of molecular matter. The other theory, which is that recently put forth by Virchow, but founded on observations and reasonings long since made by Professor Goodsir of this city, while acknowledging that, under certain circumstances, effusion of the liquor sanguinis does take place, looks upon this not so much as an exudation as an educt from the vessels by the attraction of the tissues, and the mode in which this is produced is regarded

as essentially different from the ordinary theory of exudation. In order to explain this supposition, we must remember that there are many inflammations of mucous membranes in which there is no fibrinous exudation whatever, and though in croup, for instance, we have fibrine effused in its later stages, in its earlier ones we have nothing but simple mucus. The same is the case with various other mucous membranes, some of them being more easily, others with more difficulty brought to effuse fibrine; but unless we strike all these catarrhal inflammations entirely out of the category of inflammation, for which there is no sufficient reason, we must acknowledge that there are inflammations with mucous exudation, as well as inflammations with fibrinous exudation, but we know that mucus does not exist in the blood, and is not therefore simply a transudation of the liquor sanguinis, but is the product of the mucus glands—their secretion. It is often secreted in enormous quantities, and washed out upon the surface of the membrane by the liquor sanguinis which transudes. In like manner fibrine, though it differs from mucus, in being indeed present naturally in healthy blood, and in greatly increased quantity, when the blood is, as it is said to be, inflamed, is not to be regarded when it is found aggregated in any spot, as a localisation from the blood, as an exudation, or transudation from the blood at that spot, but rather as a local product, as much a secretion as mucus is, and the increased amount of fibrine in the blood is not the pre-existing and dyscrasic cause of an inflammation, but is the result of the poisoning of the blood by the re-absorption of this local secretion. In proof of this, Virchow points to the fact that in all those cases which are characterised by the existence of a largely increased amount of fibrine in the blood, evinced by what used to be called the crusta phlogistica, or buffy coat, the inflammation affects organs richly provided with lymphatics and closely connected with large masses of lymphatic glands, while the inflammation of all those organs which contain few or no lymphatics, has almost no influence upon the blood in the way of increasing its fibrine. Inflammation of the brain, for instance—an organ which contains scarcely any lymphatics, has long been known to be unaccompanied by any phlogistic crisis, or increase of fibrine in the blood, while this is specially and largely increased in disease of the respiratory organs, which contain an unusually plentiful network of lymphatics, not only in the lungs, but in the pleura also, while the bronchial glands represent almost the largest masses of lymphatic glands possessed by any organ in the body. Further, though certain organs, as the serous membranes, secrete fibrine on the application of the very slightest inflammatory irritation, others, such as certain mucous membranes, secrete mucus on the application of a slight inflammatory irritation, and fibrine when the irritation is greater. Thus, croup is originally a mucous inflammation, at first the pseudo-membrane is a mere layer of mucus or muco-purulent matter, and after a certain time and the gradual increase of the inflammation the fibrinous secretion or so-called exudation takes place in such a manner that when we follow the succession on a piece of false membrane we have one portion which is pure mucus, and one which is pure fibrine, and an intermediate layer which is neither one nor the other. Moreover, following Goodsir Virchow disbelieves in the power of simple molecular aggregations to form cells; he believes that no cell is ever formed except by continuous generation from another cell, that all new formations originate in the natural structures of the body; and that the great source of most of these new formations, and especially of the pus cells, is the nucleated structure of the connective tissue; and he points out that if we carefully wipe off all the purulent matter from the surface of a sore, and then see what exudes, we get either pus or simply a serous fluid. There is no primary deposit of a fibrinous layer or blastema in which the pus becomes developed by the gradual aggregation of the molecule, but

it is developed directly from the nucleated cells of the connective tissues, and escapes as it is developed. Such is a general outline of the two great theories of inflammation prevalent in our day. I need scarcely say which appears most probable both from theory and from a due consideration of all the facts. It can hardly be supposed that a *generatio equivoca* is any more likely to be true in pathology than it is in physiology, while, did your time permit, I could show, as I presently shall, that the pathological history of the blood in cases of inflammation points to the existence of some continuous source of development of the fibrine; that is, it does not exist in any unusual amount in the blood previous to the commencement of inflammatory action, and ceases to be observed after it is exuded, as the crasic theorists would lead us to believe, but it is developed *pari passu* with the exudation, and gradually disappears or returns to its normal state as convalescence returns. The most modern theory of inflammation does not therefore regard fibrinous effusion, which is a well-known ultimate fact in the inflammatory process, as an exudation of a highly-organized or organizable elementary tissue, but simply as a secretion by the natural tissues, which finds its way back into the blood by re-absorption; further, that this fibrine or coagulated lymph is never transformed by molecular aggregation into connective tissue or pus cells, but is always more or less slowly absorbed—the fluid parts disappearing first, the more solid at a later period; the absorption being aided by the proliferation into it of the adjoining layers of connective tissue cells which subsequently form those cellular adhesions, so commonly met with, as the ultimate result of fibrinous effusion. 2nd. Pus is not now regarded as the product of molecular aggregation in a semi-fluid blastema, but, as in physiology we have no new development beginning *de novo*, but one animal or one plant proceeds from another by the eternal law of continuous development, which knows no exception, so in pathology, there is no exception to the minor proposition of *omnis cellula e cellula*, and pus when found in any situation is to be regarded not as anything extraneous or foreign to the organism, but merely as a peculiar morphological development of the cells naturally existing there. When a uterus is prolapsed we know that the juvenile mucous corpuscles become developed into, not mucous corpuscles, but horny epithelial cells. These epithelial cells are incapable of being transformed anew into mucous corpuscles, but on the replacement of the uterus are thrown off and replaced by a fresh development of true mucous corpuscles from the basement membrane. But those juvenile elements, which may thus become either mucous or epithelial cells, may also, when developed under peculiar pathological conditions, exhibit very early that tendency to subdivision of their nucleus which stamps them as pus cells. Pus, mucous, and epithelial cells are therefore, though not identical and quite incapable of passing into one another or performing the functions of one another, nevertheless pathological equivalents which may, under certain circumstances, be substituted for each other, and which may be developed from one and the same elementary basis. In like manner, when found in the interior of organs, the source of pus is to be found in the cells of the connective tissue, the nuclei of which subdivide under the influence of the morbid nutrition which they receive and develop themselves into pus cells instead of into ordinary connective tissue cells.

Thus we have two forms of inflammation—first, the parenchymatous, in which the process is carried out within the tissues, and the secretive or exudative, which chiefly affects the surfaces of organs, and in which there is a considerable escape of fluid from these surfaces, forming fluxes when it takes place upon a free surface, as on a mucous membrane—coryza or diarrhœa, as the case may be—and when it takes place into a cavity, as that of the pleura or peritoneum, we have the phenomena of inflammatory dropsy. The two processes are precisely similar—the one flux taking place from a free surface, the other into

a shut sac; the so-called exudation is therefore found in the one case in the spittoon or the close stool, and in the other within the cavity affected—a slight irritation of the mucous membrane leading to increased secretion of mucus, and of the serous membrane to an increased secretion of serum, a greater irritation of either complicating their natural secretion by a morbid secretion of fibrine; and leading ultimately to the proliferation of the mucous or connective tissue cells as pus in the one case and as fibre cells or pus cells in the other, according to circumstances.

From the days of Hunter the process of ulceration has been referred to an increase of absorption over deposition—a purely theoretical idea, incapable of proof, and also inconsistent with many of the facts observed—such, for instance, as the discharge of disintegrated portions of tissue, &c. It has also been referred to the corrosive action of the purulent matter, an action which has been conclusively disproved by steeping bones, &c., for weeks in suppurating cavities, after which it was found they were rather heavier from absorption than lighter from corrosion, and that no softening had taken place except that produced by putrefaction. A more recent view of ulceration is that it is caused by the slow exudation of fibrinous matter, which from the cachectic state of the constitution exhibits an indisposition to active development, and only acts by compressing the parts, more or less obstructing the circulation through them, and thus causing the gradual death and discharge of the parts affected, differing chiefly from gangrene in being more slow in action, in affecting smaller portions of the frame at once, and in the process being gradually repeated as the ulceration extends. The more modern view is entirely different, and apparently more rational. It may be thus explained:—In the natural state of the skin or mucous membrane, the upper surface we know is continually disintegrated and removed by the action of the various external influences. In health these elements are continually renewed by the continuous development of fresh mucus or epithelial cells from the basement membrane. In inflammation, however, it is precisely these young elements, which ought to become thus developed, that are transformed into pus cells, and as the epithelial surface becomes worn away, the collection of purulent matter which has been gradually forming by the rapid subdivision of the young cells, and by the effusion of serum into the intercellular spaces, gradually reaches the surface, the abscess ripens, and finally bursts; the pathologically metamorphosed juvenile elements are thrown off, and the process gradually extends into the submucous or subcutaneous connective tissue cells, and in this manner ulceration or breach of surface takes place, and this takes place all the more readily the thinner the layer of juvenile element is. In mucous membranes with cylindrical epithelium, therefore, in which this layer is very thin, it takes place much more readily than in those in which the epithelial layers are flatter and denser. In the former class of membranes suppuration hardly ever takes place without breach of surface; in the latter, as in the urethra, copious suppuration often takes place for a long time without any breach of surface.\* It has not yet been discovered whether the cells of muscle or of other organs are capable of being transformed into pus cells—it is not requisite that they should be—and it is almost impossible to ascertain if they can be, because the connective tissue is so inwoven with every organ of the body that its cells are everywhere present. The amount of destruction caused by the apparent solution of the tissue produced by the suppuration, depends upon the amount of fluidity attained by the organic matter surrounding the young elements. When this remains tolerably firm only granulations are developed; that is, those proliferations of the connective tissue cells which increase in size by the subdivision of their nuclei, before

their escape as pus cells, remain visible on the surface of the sore; as the suppuration gradually ceases these contract in size, gradually pulling together the surrounding healthy tissues, and becoming themselves partly developed into simple fibre cells, thus constituting the cicatrization of the sore—a process which was formerly supposed to be due to the renewed effusion of lymph, which became transfused partly into pus and partly into primary cells, becoming fibre ultimately, and thus constituting the cicatrix. Thus we see that the great difference between the modern theories of inflammation and those which, though less recent, can yet not be called ancient, is that while the latter calls in on all occasions the agency of a process termed exudation, and of a morbid material termed lymph or fibrine, which compresses the natural tissues and causes their death and destruction, or itself becomes developed by a *generatio equivoca*, and under the influence of unknown circumstances, into the pus cells of an abscess, the connective tissue of an adhesion, or the fibres of a cicatrix, the former deduces all their morbid elementary forms of tissue from the juvenile elements of the existing tissues, which under certain morbid influences become metamorphosed into structures, which though far from being identical with their natural physiological form, are yet the pathological equivalents of these forms, developed for certain wise purposes, and in accordance with certain laws, the nature of which is as yet unknown, but which are unquestionably framed for the protection and preservation of the organism, under the peculiar circumstances of its present existence.

The tendency of all modern thought is to assure us of the truth of the latter and more recent view of the inflammatory process, which also receives very important support from the results of enlightened treatment. But into all these matters we must subsequently go more in detail; it is enough for the present to have shown, somewhat cursorily, that inflammation is no morbid novelty, but merely the result of the natural laws of vitality, and of the ordinary growth of tissue, operating under certain anomalous conditions.

## PUBLIC HEALTH AND SANITARY REFORM,

DELIVERED BEFORE THE DUBLIN STATISTICAL SOCIETY.

By Sir R. J. KANE, M.D., F.R.S.

(Continued from p. 564, Vol. ii., 1866.)

MYSTERIOUS and complicated as are those phenomena, analogous to fermentation, by which it is supposed that certain contagious or zymotic diseases are produced, that process does not suffice to explain all the circumstances under which disease is communicated, and we are obliged to admit that in many, and in some of the gravest instances, morbid influences are propagated through the agency of beings of a higher organization. Science has demonstrated that man and other animals are themselves the material means and pabulum of existence to myriads of beings more or less minute, and of which, in many cases, we can only infer the existence from their lamentable effects. That probably every living organism is itself truly a microcosm, a world in itself, in which infinite series of lesser organisms live and die, carrying in their life or in their death the elements of disease and inevitable decay to the being in which they have been formed. We thus may recognise among the maladies which are known as infectious or contagious the two groups of fermentative and of parasitic diseases; of the former we may regard small-pox as the characteristic type, with probably oriental plague and the cattle disease, from whose ravages this country has so far fortunately escaped. In those the virus may be transferred by inoculation, and acting on materials naturally existing in the blood, generate by a fermentative action, matter of the same kind, which often tends to eliminate itself from the system under various

\* We can readily understand that small fragments of the tissue get broken off, and occasionally washed out with the discharge, and that when the ulceration affects the bones the insoluble calcareous matter is found mixed with it.

external forms. Not so easily explained as results of fermentative action are the phenomena presented by the spread of the contagion of Asiatic cholera and typhus fever. Those terrible pestilences appear to inflict their ravages by further means, and many phenomena appear to lead to the belief that those and some similar forms of disease are generated by means of minute beings, which, being diffused through the atmosphere, settle down on certain places, or on certain individuals, in a most irregular and anomalous way, although in all cases favoured by want of cleanliness, drainage, and ventilation, and often directly supplied through water and through communication with diseased persons or places. Such diseases do not admit of being directly reproduced by inoculation, nor can, in most cases, any distinct virus be exhibited; but this is probably due to the imperfection of our means of investigation, and not to any real distinction in the two classes of disease. The transference of such organic germs is illustrated by the curious form of fever which has been epidemic for the last few years in Central Germany, and which has been traced to the development in the muscular tissue of the human body of a microscopic worm, the *trichina spiralis*, which obtains entrance from diseased meat, especially pork, having been used as food. In this extraordinary disease, every part of the muscular tissue becomes infested with this minute animal, and a small bit of diseased muscle, if inserted in the muscle of a healthy animal, transplants the parasite, which then lives and multiplies in its new position, to the imminent risk of the individual who has afforded it a home. It may interest some of my friends here to know that this little worm, although showing utter indifference to every kind of drug, has an intense dislike to alcohol, and the only individuals in Central Germany who have been latterly able to eat diseased meat with impunity have been those reckless individuals who washed down their roast pork and sausages with copious libations of corn brandy.

From the more definite knowledge of the nature of contagious influences which those observations will serve to indicate, it is apparent that in placing cleanliness, personal and domestic, at the head of the means for preventing or checking the spread of disease, I but carried out the strict principles of science. Every collection of filth, every space occupied by stagnant water or often respired air, becomes a favourable position for the growth and diffusion of those germs of infection. By their being diluted and removed by fresh currents of air, by frequent ablutions, and by drainage, their power to do evil is abated if not destroyed, whilst the freshened energies of life conferred upon the system by the action of those sanative means, enable the organs to resist and to reject those morbid influences to which otherwise they might have succumbed. To those means of resisting disease, however, we need not be necessarily restricted; we may call in the assistance of science in another form, and not merely removing the infectious matter, we may altogether destroy and decompose it by means of suitable disinfecting agents.

Under the name of disinfectants are, however, often confounded two different classes of agents which it is very important to distinguish: Those which merely disguise, and those which really destroy the morbid matter. So invariably are filth and disease associated that the fetid emanations, which cleanliness and ventilation would soon remove, are often confounded with the actual substance of contagion, and it is thought that by perfumes and fumigations which can overpower by a stronger smell the fœtor of dirt and sickness, the danger of infection can be removed. This has often proved a fatal mistake, although often also it has acted beneficially by inspiring confidence and exalting the vital force which then was able to escape occasions of disease, under which otherwise the system might have sunk.

Nothing can be considered as really a disinfectant but what can actually destroy the organic germs upon which the propagation of disease depends. Of such bodies

chlorine is by far the most available, and the most powerful. The direct decomposing action which it exercises on all organic bodies, and the consequent destruction of all vitality in organic germs, such as might propagate disease, renders it the most valuable agent for sanitary purposes that we possess; whilst the facility with which it can be applied in various forms, as gas, as liquid, and in solid combination, enables it to be adapted to the most varied circumstances. It is only necessary to avoid the liberation in any confined space of such a quantity of chlorine gas as might affect respiration, or produce irritation of the lungs; and this is easily done. Gaseous chlorine when respired has no other injurious effect; it is not in any way poisonous. Many other chemical agents which combine with or decompose organic bodies are also excellent disinfectants, as sulphurous acid, and especially permanganate of potash: this body, which is a very powerful oxidizing agent, is now very frequently employed to detect the presence of abnormal quantities of organic matter in air or water. In fact, any substance which is capable of arresting fermentation by destroying the vitality and energy of the organisms which constitute an active ferment, will, for the same reason, arrest and destroy the matter of contagion.

These disinfecting agents, chlorine especially, have the property of destroying foul smells by the same process, of changing the nature of the fœtid material, and generating other bodies which are free from practical inconvenience. They are therefore very usefully employed for the purpose of deodorizing or disinfecting, those words being popularly considered synonymous, the sewage and other similar materials which should otherwise become offensive nuisances. It is, however, very necessary to distinguish between these two actions: an atmosphere apparently pure and bright may be loaded with typhoid emanations; a water clear, fresh-tasting, and sparkling may be infected with the cholera poison derived from drainage through the soil from the neglected sewage of neighbouring infected places. On the other hand, the air of a chemical laboratory, or of a manufactory, may be offensive from the escape of ill-smelling gases or vapours, and yet be totally incapable of producing contagious disease. An atmosphere may, however, be injurious to life from the presence of directly poisonous gases independently of any power of producing contagious disease; and may thus be vitiated by overcrowding, by exhalations from cellars and pits, by the proximity of lime or cement kilns, which diffuse the poisonous gases, carbonic acid, and carbonic oxide. Such air may be rapidly fatal if respired, and yet present no sensible indication of the danger. On the other hand, although sulphide of hydrogen is extremely poisonous when respired, such is the disgusting smell and taste of air containing even one ten-thousandth part of its volume of that gas, that attention is at once called to its presence, and the danger may be avoided. By means of chlorine this poisonous gas is at once destroyed, other compounds being formed which are free from any injurious properties.

A very interesting subject has been discussed lately in relation to the salubrity of the atmosphere, in which a peculiar material termed ozone has been supposed to play an important part. You will find an excellent *resumé* of what has been suggested regarding this ozone in the Lectures on Public Health delivered by Dr. Mapother. It is certain that the free open air of the country, and particularly near the sea, presents to re-agents many of the characters which belong to ozone, or rather to the presence of an oxidizing agent, for the ozone itself is believed to be a modification of the natural oxygen of the atmosphere, and that this oxidizing or ozonic re-action of the air is lost or absent in air which has been often breathed, or that is vitiated by the emanations of decomposing organic matter. It is hence pretty certain that air presenting the re-actions of ozone is purer and better suited to support energetic life than the air more or less foul which does not show this re-action; but whether this

oxidizing re-action in the air is in reality due to the presence of ozone has been latterly more and more called in question. The same re-actions are produced by the presence of minute traces of nitric and nitrous acids. These bodies are continually generated in the air by the unceasing disturbances of electrical equilibrium. The gradual oxidation of organic matter which takes place on the surface of the soil, and in the air itself, also generates those acids, and their quantity in the atmosphere is usually such as to fully explain the re-actions which have been attributed to ozone. I do not myself express an opinion on the subject; I only give the results of chemical inquiry so far as it has yet been carried on. It is, however, certain that the air itself is constantly and powerfully converting the effete organic residues of animal and vegetable life into the materials from which new forms of animals and plants are to be produced, and that thus the never-ceasing cycle of vitality ordained by an all-wise Providence is harmoniously carried on—the close of one phase of physical existence supplying the materials from which the substance of the plants and animals of a succeeding generation are to be formed.

This is no merely abstract or speculative principle. The successive utilization of the same material elements in the formation of successive phases of organic life is the basis of practical agriculture; on it rests the whole science of the application of manures. It has the most direct influence on the economy of large cities and on the prosperity of nations; for there is little doubt but that after allowing for the moral and political agencies which contributed to the destruction of the great empires of antiquity from Babylon to Rome, no insignificant element is to be found in the impoverishment of the neighbouring territories, the produce of which was consumed within the great cities without any equivalent being returned to the soil. Hence those lands became finally incapable of supplying food, and the population became dependent on the produce of distant countries, with which a political connection unstable and precarious could not permanently be maintained.

On a smaller scale the same process is going on in modern nations, and indeed with an accelerated pace among ourselves. Every country which is an exporter of food, diminishes by so much its power to produce food. The mineral elements of food, the earthy phosphates of which the bony skeleton is composed exist in the soil, but only to a limited extent, and the supply should soon come to an end if not compensated for by the restoration of as much of the same material under the form of manure. In new countries according as the soil of one district becomes exhausted, the cultivation passes to another, but even in America this can no longer be easily done. With us it is of course impossible, and we must bear in mind that for every ton of bone that we send out of the country we are so much poorer in capital, unless we replace it by a ton of bone brought from some other source. Hence the influence of a large city like Dublin is necessarily to impoverish the soil of the surrounding districts, unless means be taken to restore to the soil the residual materials of the food which has served for the support of the inhabitants. The question of sewage, to which I have already referred in connection with the means of health and cleanliness, assumes thus additional importance when considered in relation to restoring the productive powers of the soil. The utilization of town sewage, however, must depend for its practicability on many complex conditions as to form and locality, upon considerations not merely of chemical and engineering skill, but also of financial prudence. Into those matters it would be impossible for me to enter; as regards this city the subject is in the hands of the municipal authorities, assisted by eminent professional opinions, and from what I have seen of the plans recently under consideration, I have no doubt that before very long we shall see our river and its quays restored to their primitive salubrity, whilst what is now a source of defilement and disease, will afford the means of reclaiming new lands to

profitable cultivation, and afford new sources for the supply of food.

I have thus endeavoured to explain in a simple form the general principles of sanitary science, as constituting the third branch of the business of this Society. We have seen that a large class of those diseases which are most destructive, especially to the poor, are in a great degree preventible, by the adoption of simple hygienic means, by cleanliness, by ventilation, and by the use of those disinfecting agents which science teaches us to employ. In the foregoing remarks I have not adverted to that which lies at the basis of all sanitary requirements: the means of providing for the people a proper supply of food. Good and sound nourishment is in itself a powerful sanitary agent, enabling the system to resist tendencies to disease, under which, with a lower standard of living, it would have sunk. So direct is the connection between zymotic disease and want of food that the term famine fever has been adopted in medical classification for that form of epidemic of which in 1847 we had in this country so fearful an example—we must not, however, now enter into that subject. The means for providing the people with good and abundant food is to be found in facilitating the access of the people to industrial employment, and rendering that employment grateful by securing that the worker shall enjoy the product of his toil. In such form, however, the question touches upon matters belonging rather to the practical statesman than to the statistical inquirer, and on which it would be unsuitable for me to dwell.

In another aspect, however, the influence of sanitary conditions on the material and financial conditions of the working classes may legitimately be considered here. In no way is the suffering from sickness more severely felt than in the destitution which almost invariably attends the protracted illness of the bread-winner of a family, and the consequent loss of the weekly wages upon which the support of a wife and children usually depends. The inevitable reduction in the amount and quality of food; the absorption of any little fund of savings which the providence of better times had formed; the pledging of the little stock of furniture and clothing; the gradual sinking into destitution, and the loss of energy and hope which throws the family into the conditions most conducive to the still further propagation of disease. It is true that in most of the trades benevolent societies are organized, from which, when properly conducted, great benefits are derived, and much assistance is afforded to their members suffering from sickness; but the sphere of action of such societies is still very limited, and the actual loss of money capital, not to speak of physical suffering and moral depression, consequent upon the spread among the working classes of preventible diseases, presents proportions well calculated to arrest attention when we submit it to inquiry.

My friend Dr. Mapother has very kindly obtained for me some returns illustrating the proportion of time lost through sickness by the working men in various employments in this city. Those estimates, into the details of which I need not enter here, as I hope the subject will be brought fully under the notice of the society at another time, represent the proportion of illness under the circumstances which render it a minimum, as in those employments no absolutely sickly person would be retained. It appears, however, that the average time during which a workman is prevented from earning by illness is from four to twelve days in the year, or as we may take it  $2\frac{1}{2}$  per cent. of the whole period. Now as there is estimated to be in Dublin of the classes living upon wages 100,000 individuals, we may judge how great, even when taken at its lowest average rate, must be the actual loss in money to the working classes, and consequently to the State, from illness of which, as one-fifth of the total deaths are estimated to result from zymotic diseases, a large part could be avoided by the adoption of sanitary precautions.

But the amount of money measured in this way represents but a very small part of the injury to society, and

loss of capital which results from the spread of disease among the working classes. I have mentioned in the early part of this address that the mean value of life in this country is forty-one years, which signifies that every child born may be expected in average to live so long. But if the perils of childhood have been escaped, then the value of life becomes much greater, and a person who has arrived at manhood in health, may be expected in average to survive to the age of sixty-three years. This should allow of marriage, and of the children being reared until the youngest was able to earn its subsistence, and under those circumstances, the family is self-supporting; it is a strength and stability to the State as an element of population; but if from exposure to contagion, or other influence of disease, the provider for such a family dies before the children have attained such power of independent existence, then the family is thrown upon its friends or upon the poor-rates for support, and hence we have in our workhouses such numbers of widows and orphans hopelessly supported at the public charge. Contrast with these sources of unproductive expenditure, the cost of any or all of the sanitary provisions which have been or may be proposed, and it will be seen that whether we regard our water supply, our sewage arrangements, or other means for bringing cleanliness and comfort to the dwellings of the poor, not merely do the dictates of philanthropy and of Christian charity direct them to be carried out in an abundant and liberal spirit, but the narrowest instincts of self-preservation, and the practical calculation of ultimate economy teach us the same lesson.

In this city, where the excellence, the numbers, and the importance of our medical charities are so well known, it is not necessary for me to refer to the subject of medical assistance in connection with sanitary reform. Medicines, and even the most sedulous care on the part of the physician, do not suffice to alleviate the mental and bodily sufferings of the fever-stricken father, or console by timely and appropriate assistance the anxious family. For such aid a more tender and sympathising helper must be sought, and whether we look to the wards of our splendid hospitals, or to the crowded lanes and alleys of our town, we find on this sacred mission the nursing Sisters of Mercy and of Charity, defying all that is repulsive to our weaker nature, all that is most dangerous in pestilence and death, to bring to the bed of sickness whatever can tend to physical relief, to the pillow of the departing the words of heavenly peace and hope. That holy ministry of truest charity is fortunately not limited to the members of one country or of one creed. The name of Florence Nightingale, honoured everywhere, and loved by all, typifies the same burning charity which kindling in other breasts a similar ardour, has given origin in London, in Liverpool, and in other cities, to the missions of trained district nurses among the poor, and to the formation of schools for educating nurses for hospitals, and for private requirements. By such means a want will be supplied which every physician and every person conversant with the necessities of the sick, rich as well as poor, has felt to be of great importance. To such enterprises, most useful auxiliaries to the progress of sanitary reform, we can give our entire approval. Let us hope that we shall before long see still farther extensions of such practical beneficence among ourselves, bearing in mind the words of the Apostle, that of the three things which abide amongst us, faith, hope, and charity, the greatest of all is charity.

I feel that I have occupied this assembly to an unseemly length, and perhaps exhausted your patience: but the subject was one which from its scientific interest and its practical importance, carried me further, almost against my will, than I had at first intended. I thank you for the kind patience with which you have heard what I had to say, and I hope that this meeting will prove a good augury of the session which the Society has now commenced.

## Original Communications.

### THE SURGICAL TREATMENT OF ANCHYLOSED HIP-JOINT.

PART OF A CLINICAL LECTURE DELIVERED AT ST. MARY'S  
HOSPITAL.

By HAYNES WALTON, Esq., F.R.C.S.,

SURGEON TO THE HOSPITAL, AND TO THE CENTRAL LONDON OPHTHALMIC  
HOSPITAL.

GENTLEMEN,—The next case on which I lecture is that of ankylosis of the hip-joint. All of you know the patient well, as I have frequently drawn your attention to him. A clinical lecture is of little value to you except you have watched the subject of the discourse.

I must preface my remarks by saying a few words on ankylosis.

By an ankylosed joint, complete bony ankylosis is meant—destruction of the joint, fusion of the bones by new osseous matter, and, therefore, loss of all motion.

There is a variety of this, in which there are arches of bone, or an imperfect ferrule around the joint, while the interior of the joint is destroyed and supplanted by fibro-cellular element that ties the bones together very firmly.

This must be considered less disease than the remains of disease. It is what disease has done. It is a reparative process. It is that which we often desire and endeavour to bring about, in that state of joint affection in which the tissues of articulation are removed by suppurative or ulceration. The failure of it often destroys life, and often obliges the loss of a limb to save life. It is a state, however, that I have nothing to do with at present.

Incomplete ankylosis is that with which we are concerned to-day. It is sometimes called fibro-cellular ankylosis. There is no bony union. There is not immovability of the joint, but more or less of motion.

The stiffness may be caused by inflammatory change in the capsule; certain thickness by fibroid bands in the joint; a partial destruction of the synovial membrane and the fibro-cartilage in the joint, and the establishment of fibro-cellular bands.

I shall not consider the effect of muscular contraction in adding to this ankylosis, as it does not concern what I intend to illustrate.

This, also, is a state of repair, and that which we should often attempt to establish.

Incomplete ankylosis comes within the scope of practical surgery.

In certain fit cases we may do good by interfering. We may break down the adhesions or stretch them enough to fulfil our desired purpose. Treatment then may be undertaken to alter the prejudicial position of a limb without any intention of the restoration of motion.

If an elbow be ankylosed in a straight position, it is right if we can to put it in the more convenient one of being bent. A bent thigh may be advantageously put straight, and a bent knee also straightened.

Or it may be prudent to attempt to remove the ankylosis in whatever position the limb may be, with the view of restoring motion—*i. e.*, the power of the limb.

On the diagnosis of the degree and kind of the ankylosis must this treatment depend. A careful examination of the part is needed, and still more the history of the affection. It is here that real practical anatomical knowledge is needed; you must have a thorough knowledge of the joint at your fingers' ends, for without that you cannot detect the alteration in the many parts, in observing which must your diagnosis depend. Theory or mere book education is useless. If you are not fortified in this way, you had better send the patient elsewhere.

In the case which is the subject of this lecture, I

operated to effect both objects—to straighten the thigh and to restore the use of the limb. The first may be undertaken in any degree of muscular degeneration. The latter only when the muscles are in their integrity, or nearly so, therefore only in recent ankylosis. It is a nice question to decide when this is admissible, and only a practical acquaintance with such cases can guide you. Some years ago a gentleman had his right knee and right hip-joint ankylosed; his leg and thigh muscles were shrunk. He managed to hobble about with a crutch, and could get up and down stairs. A surgeon who was consulted broke down the ankylosis of both joints, and the patient was placed in a worse plight than before. He had not the least power over the limb. He could not move any part of it an inch. It became necessary for him to wear a complicated apparatus to stiffen the two joints, but with it he never could get about as well as before the operations.

In contrast to this I will mention a case which occurred to me in private practice, in which I did obtain perfection. A gentleman, while playing at cricket, received a blow on his knee from the ball. Inflammation of the joint followed, and the knee became slightly bent and stiff, without, however, any muscular contraction. I could not detect externally any abnormal condition of the joint, and therefore I concluded that the cause of the imperfect ankylosis was slight, and that as the muscles of the limb had not undergone any wasting, I hoped to break down the ankylosis and restore perfect motion to the joint. The operation was performed under chloroform, and I was assisted by my then colleague, Mr. William Coulson. The adhesions, whatever they were, gave way very readily, and perfect motion of the leg, with perfect use of it, was thoroughly restored. Now, after the lapse of several years, the gentleman cannot tell that there is any difference between the legs.

It is especially in the rheumatic cases to which we should look for opportunities of success, because the inflammation generally attacks the capsule of the joint and produces changes in it without extending into the joint. Occasionally there is osseous material in the cellular tissue around the joint. In what may be called joint disease *per se* without the co-existence of rheumatic fever, the interior of the joint is first invaded with disease, and if ankylosis follow, we may be sure that the new connection is extensive and firm.

You will remember that I examined my patient thoroughly on Wednesday last, and showed you what a beautiful result had been obtained.

He is thirty-two years of age. Some months ago he got rheumatic fever, and was confined to his bed for nine weeks, during the latter portion of which time his left hip-joint became affected with articular rheumatism. I could not get the history of the case in detail. Some weeks after he was about, he was sent to this hospital, and became admitted under the care of Dr. Handfield Jones, who, discovering that there was nothing the matter but a stiff hip, transferred him to a surgical ward under my care.

I found the hip in a bent position; therefore the indication was to straighten it. I expected to accomplish this with ease, because there was every probability of the interior of the joint being healthy, and of the stiffness being due to the parts around the joint, including the capsular ligament, and I was tolerably sure that even here there was no great morbid change. Besides, as the muscular condition of the limb was scarcely altered, I hoped to restore the use of the limb as well. Therefore, I went for the double object, to straighten the limb and to restore motion. To accomplish this, it was necessary, in breaking down the ankylosis, to give the joint a full range of motion, to extend it, and to flex it to its utmost. If my object had been merely to straighten it, I should have done that and not have flexed it at all. Chloroform was administered, and I commenced my operation. I have no

doubt that you were much astonished at the ready manner in which I effected my object, and the very audible sound which you heard when the limb gave way under my pressure told you that something had been ruptured. Before the patient left the table you saw me move the limb through as wide a range of movements as the other was capable of being put through. No local disturbance followed the operation. I do not think anybody has been more surprised at the result than the patient himself. In ten days he was getting about with his crutch. The limb was flexed and extended every day a little by the house-surgeon. The patient can now stand alone without his crutch and make a few steps. I doubt not that in a month or two he will be able to go about his usual occupation with full satisfaction. It was my wish that he should remain a few weeks longer at the hospital, but his desire was to go home, and he left yesterday. He has promised to come and show himself from time to time, and I will take care when he does come that you shall see him.

It is astonishing how little constitutional effect follows this breaking-down treatment, and this is, doubtless, because the wound or tear that is made is excluded from the contact of air. Although in common with every operation in surgery it is not devoid of some risk, I can say, after a long familiarity with such practice, I have never seen any ill consequences.

You should clearly determine whether, in any given instance, this treatment is admissible or not, and well understand what it is you intend to do. It is of equal importance that the true nature of what is undertaken be fully explained to the patient, and that he be made to understand that it can be but very rarely that what may be called a perfect result can be got, because there is seldom those conditions that will admit of it. He may be disappointed except this be done. Do not deceive yourself and him by expecting more than can be attained. Nearly always you are operating on a part that has been spoiled by disease.

### SUCCESSFUL CASE OF EXCISION OF THE KNEE-JOINT.

By S. K. CRAWFORD, M.D., L.R.C.S.Ed.

E. S. McM., at 18, gives the following statement of her case:—About three years ago, while living as a servant, she was ordered by her master to carry a burthen into the garden, leading to which were a number of stone steps; going up these she slipped and hurt her knee; she went through her ordinary work for some time, complaining slightly of pain, to which she paid no attention until it became so severe she was compelled to leave her situation and return home. Having kept quiet for some time the knee improved a little, the pain having in a great measure subsided. She then went to work in a mill, to and from which she had to walk two miles night and morning; here she remained for about six months, when she was again compelled to remain at home. At this time she consulted with and received medicine from another medical gentleman, and occasionally came to my dispensary without receiving any benefit, as by the constant use of the limb she kept up the irritation until ulceration of the cartilages had set in. A short time before the date of operation she had gone to hospital, thinking to be benefited, but she was told nothing could be done for her except amputation, to which she objected and returned home. After her return her mother consulted me concerning spasmodic pains in her bowels from which she suffered. I asked her how her daughter's knee was, when she informed me about her having gone to hospital, and being told there, and elsewhere, of the necessity of amputation; I told her of the possibility of saving the limb, and she called next day to ask me to visit her. I accordingly did so, and having

made a minute examination of her case I proposed to excise the joint, to which, after having consulted with her friends, she agreed.

On the second day after I, with my own assistant, performed the operation, having first secured the services of a steady labouring man to render assistance should the patient become restless. Mr. MacCormac, my assistant, having administered and attended to the chloroform, I made the necessary incisions and removed the diseased surfaces of the femur and tibia, and also part of the under surface of the patella. I then stopped the hæmorrhage from the vessels by torsion, stitched the flaps, and dressed with lint and oiled silk, which done I placed the limb in the straight position in a box made for the purpose with a movable foot-board.

About five hours after I again saw her, and found her recovered to a remarkable degree from the effects of the chloroform and immediate shock of the operation. I ordered her a chlorodyne draught and left her. In the morning she informed me she had slept well during the night, and felt little pain. I continued to administer the chlorodyne at night, and when the fever had subsided I ordered her wine and beef-tea. She complained of the wine not agreeing with her stomach, and I substituted whisky and water, which seemed to agree better with her. On the third day after the operation I dressed the knee, from which healthy pus was exuding in considerable quantity. On the sixth day I again dressed it and found union by the first intention had taken place, except at the angles of the inner and outer incision, from which pus continued to flow, diminished in quantity, and retaining its healthy appearance. The apertures at the angles then commenced to granulate from the bottom upwards, and in about six weeks these were completely filled up.

At the end of the seventh week the wounds were completely healed; and at the expiration of the twelfth week I considered her so far recovered as to remove the box in which the limb was placed.

She now commenced to move the limb gently by drawing it upwards, and then rotating it from side to side.

She continued to improve, and on the nineteenth week she was able to walk about the house supported by a stick, but suffering from slight stinging pains in the knee, which gradually subsided. On her first attempt at walking the unaffected limb by long disuse felt almost as feeble as the other, and it required a little time to enable her to proceed with confidence, holding by whatever she could grasp.

The limb is shortened by about three-fourths of an inch, which is an advantage in enabling her to bring it forward with greater ease.

This case is one of considerable importance, showing the necessity of making as thorough an examination of the joint as possible, in order to ascertain how far the disease may have proceeded, that we may give the patient the use of a real limb, although with a stiffened joint, in preference to an artificial one.

## Hospital Reports.

LONDON HOSPITAL.

### ATONY OF THE BLADDER FROM STRICTURE IN THE URETHRA.

(Under the care of Mr. CURLING, F.R.S.)

JAMES COLMAN, a married man, 36 years of age, of nervous temperament and rather feeble constitution, a farm labourer, was admitted into the hospital Nov. 6, 1866, in consequence of being troubled with a constant dribbling of urine. It appears that he had suffered from stricture

in the urethra for some years, and about ten months before he had an attack of retention of urine. He came to the hospital, and was relieved by a catheter, and after being treated for a short time for a stricture, was made an out-patient. Since this attack he has always had difficulty in relieving his bladder, and latterly he has been greatly troubled by his water dribbling from him night and day. Mr. Curling saw him shortly after his admittance, detected a distended bladder by percussion, and, without much difficulty, passed a No. 4 catheter through two strictures into his bladder. A very large quantity of urine was drawn off. Mr. C. put him upon a good diet, and directed his bladder to be emptied by a catheter daily, the size being gradually increased.

16th.—The urine had ceased to dribble away during the day, and he was able to retain it from two to three hours, and to void it to a certain extent. A little water still passed from him involuntarily during the night, and he had to get up four times to get ease. He was ordered to take the citrate of iron with strychnia.

29th.—The dresser is able to pass a No. 9 catheter, and finds that the patient is now capable of nearly emptying his bladder; urine pale, and rather copious; ordered twenty drops of muriated tincture of iron three times a day.

30th.—Discharged cured.

In the course of some clinical remarks on the above case, Mr. Curling said that its nature might easily be overlooked by those unaccustomed to treat diseases of the urinary organs. He then pointed out that the history of the case showed that the bladder had been greatly over-distended in an attack of retention. After the urine has been thus retained the muscular coat of the bladder does not regain its contractile power, consequently the urine accumulates up to a certain amount, when distension of the neck of the bladder allows its escape, and the urine then goes on dribbling away, more or less in proportion to the quantity secreted. The fibres of the bladder are now unequal to the task of expelling its contents, especially through a strictured channel. They have been over-stretched and in this way have lost their tone. Even after drawing off the urine daily and thus preventing distension, it will be found that the expulsive power usually returns but very gradually, and sometimes not at all. In this case under treatment for sixteen days, the patient had regained the power of micturition. He could hold his water for two or three hours, and exercise sufficient expulsive power to void the whole of the urine in the bladder.

Mr. Curling then pointed out that this condition is not, as some might suppose, a paralysis of the bladder, but an atony, a loss of tone and power from over distension. A similar state of things is sometimes met with in the rectum, as pointed out in the lecturer's work on diseases of that part,\* in which there is a chapter entitled, "On Atony of the Rectum," where cases are described of loss of tonicity and defective muscular power in the lower bowel, preventing the proper extrusion of its contents.

Mr. Curling then went on to show how the atonic state of the bladder in this case, arising from over-distension, may be contrasted with a not uncommon condition, arising from some impediment to the escape of the urine. For example: a thickening of the bladder, chiefly owing to hypertrophy of its muscular coat; in their frequent efforts to overcome the obstruction, the muscular fibres acquire an abnormal development—the exact opposite to the state of the bladder seen in cases of atony. The treatment adopted in the case reported above was complete emptying of the bladder with the catheter once a day. This process prevents too great accumulation of urine, enables the muscular fibres of the bladder to contract, and at the same time distends the strictured part of the urethra. To give strength and tone to his system he ordered the citrate of iron and strychnia. At a later period he sub-

\* Diseases of the Rectum, by T. B. Curling, F.R.S., Surgeon to the London Hospital.

stituted the muriated tincture of iron to improve the quality of the secretion.

The result was quite satisfactory, and the recovery of expulsive power more rapid and more complete than usual.

## RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

### Dr. LYONS'S CLINIQUE.

*Capricious Sporadic Oculo-Facial Paralysis.*—Under this term Dr. Lyons proposes to describe a form of paralysis of very unusual occurrence, and presenting very remarkable features. It was well exemplified in the following case:—

K. O'M., unmarried, aged about 25, was admitted into hospital under Dr. Lyons's care. She stated her occupation to be that of a milliner, and asserts that, with but very slight premonitory symptoms, such as slight localised pain in left temple, it was observed to her by one of her companions in the work-room that she was beginning to squint. She soon found this to become a confirmed condition, and that, moreover, there was double vision. She felt much alarm, and when admitted was exceedingly apprehensive as to the results of this strange affection. On very careful examination it was found that double vision, with paralysis of sensation of a large surface of the eye-ball, loss of sensation of smell at the left side, and total insensibility of numerous parts of the side of the nose and face externally, as well as of the mucous surface internally, were present. The paralytic phenomena were all strictly confined to the left side. On further exploration it was ascertained that the double vision was wholly due to paralysis of the external rectus of the left side. In causing the patient to roll the eyes right and left, it was found that the left external rectus could bring its globe to about the position of "eyes front," but no effort could drag it beyond that. While, then, the axes of vision could be consentaneously moved by the right external rectus and left internal rectus, vision was single and perfect, and in all movements of both eyes to the left, the left eye stopped at "eyes front," while the right was drawn in towards the nose and all objects were consequently seen double. Pricked with a needle smartly the globe of the left eye was everywhere insensible. The lids were insensible externally and but partially so internally. The nasal twinge of the ophthalmic was insensible where it becomes superficial, and the left side of the nose internally as well as part of the left side of upper lip externally was insensible, and parts of the palate of same side failed to recognize the needle point. In some situations the lip externally was insensible, and at a precisely corresponding part internally sensation was present.

Having fully exhausted the phenomena of the case in repeated explorations, Dr. Lyons, from a previous experience of this form of paralysis, was enabled to give a reassuring diagnosis, and remove the painful and depressing apprehensions of threatened mischief to the brain previously entertained. The eye was found healthy by the ophthalmoscope. A confident opinion was likewise expressed that the squint would be cured. A careful but generous regimen was prescribed, a blister was applied to the external wall of the orbit, and bromide of potassium was administered. Electric shocks were likewise employed for a considerable period, and eventually the continuous galvanic current was applied to various parts of the face, and as efficiently as could be done, by means of a needle point to the external rectus.

After a long period, part of which only was spent in hospital, complete convalescence was established in this case.

In a second case, the particulars of which will be given more at length in another report, Dr. Lyons has met with this form of paralysis, and under circumstances in which

still greater complication and difficulty of diagnosis existed.

The patient was aged 60, a man of sedentary and very studious habits. Double vision with ptosis suddenly occurred, and as there was partial loss of taste, the most unfavourable augury was held with regard to the issue of the case, softening of the brain being apprehended.

After most careful exploration of all the phenomena, Dr. Lyons gave a favourable prognosis, which was fully justified by the ultimate complete restoration to health of the patient, with perfectly single vision.

## CHRISTMAS AT THE ROYAL INSTITUTION.

On Thursday last we had the pleasure of hearing Prof. Frankland open his course of six lectures on the chemistry of gases, adapted to a juvenile auditory. The theatre was crowded with an attentive audience, and the experiments were very successful. Not a few of the listeners, however, could lay but little claim to the term juvenile; for, though a very large preponderance of the young was observable, yet many full-grown and even elderly people had been attracted to this rational Christmas entertainment.

The following syllabus will give the reader the scope of Professor Frankland's lectures:—

### SUBJECTS OF THE COURSE.

Distinction between Solids, Liquids, and Gases.  
How to collect Gases.

Transference of Gases from one vessel to another.

**HYDROGEN.**—Its extraction from Water and from Acids—Its combustibility—How it burns, and what it produces when burnt—Colourless Gases rendered visible.

**OXYGEN.**—Presence of this Gas in Air and Water—How to obtain Oxygen from the Air by Quicksilver, and from Water by Chlorine and by Electric Decomposition—Preparation of Oxygen from Potassic Chlorate (*Chlorate of Potash*)—Chemical combination of Oxygen and Hydrogen—Relations of Oxygen to Combustion.

**NITROGEN.**—Extraction of this Gas from the Air—Composition and Properties of Air—Spontaneous mixture of light and heavy Gases.

**CARBONIC ANHYDRIDE (Carbonic Acid).**—How to get this Gas out of Marble and Limestone—Its relations to Combustion—Permanent and transitory Gases—Liquefaction of transitory Gases—Liquefaction and Solidification of Carbonic Anhydride—Great Cold produced by the Gasification of a liquefied or solidified Gas.

**CARBONIC OXIDE.**—Its preparation from Charcoal and Carbonic Anhydride—How it burns in Air and what it produces when burnt.

**MARSH GAS.**—Its occurrence in Coal Mines—How to get this Gas from Ponds and Marshes, and from Hay, and other Vegetable Substances—The Combustibility of Marsh Gas and its Explosiveness when mixed with Air or Oxygen.

**OLEFIANT GAS.**—Its extraction from Alcohol—Combustibility and Luminosity of this Gas.

**NITROUS OXIDE, OR LAUGHING GAS.**—How to prepare and collect this Gas from Ammoniac Nitrate (*Nitrate of Ammonia*)—Curious effects of Nitrous Oxide upon Animals.

**HYDROCHLORIC ACID.**—Preparation of this Gas from Common Salt and Sulphuric Acid—Its Collection over Mercury—Its solubility in Water.

**CHLORINE.**—Extraction of this Gas from Hydrochloric Acid—Chemical energy of Chlorine at Common Temperatures, and under the influence of Light—Combination of Chlorine and Hydrogen—Bleaching powers of Chlorine.

**AMMONIA.**—Preparation of Ammonia from Sal Ammoniac, and Regeneration of the latter from Ammonia and Hydrochloric Acid—Acidity of Hydrochloric Acid—Alkalinity of Ammonia—Neutrality of Sal Ammoniac.

**PHOSPHORETTED HYDROGEN.**—Action of Water upon Calcic Phosphide (*Phosphuret of Calcium*)—Spontaneous Inflammability of Phosphoretted Hydrogen—Comparative Inflammability of different Gases—The Philosophy of Combustion

Effects of Heat upon Gases—Remarkable properties of hot Gases—The Light emitted and absorbed by hot Gases. Spectrum Analysis—How hot Gases are detected in the Sun and Stars.

## Reviews.

LECTURE NOTES FOR CHEMICAL STUDENTS, EMBRACING MINERAL AND ORGANIC CHEMISTRY. By EDWARD FRANKLAND, F.R.S., &c. London: John Van Voorst, Paternoster-Row.

THE last two years have been prolific, as regards the production of English works connected with Chemical Science. Amongst others we have two of the first professors in London constructing elementary works for the use of students, and both of them have adopted, *in toto*, the notation and equivalent numbers used by modern theorists. The new system, which is to be partially adopted in the pharmacopœia, has certainly received a rapid expansion within the last few years from the labours of the English chemists, both by their practice and writings. If we except the labours of Berzelius, we may claim the birth of these views as having emanated from our own country many years ago, but there is no doubt that their primitive development occurred in France. It is in England, however, that these changes have been really taken up and placed upon a substantial basis, by the publication of works of reference, manuals of instruction, and essays upon original research, in which the various authors have completely ignored the old views.

When such a man as Edward Frankland gives a book to the world it will be sure to obtain a greater share of attention than a more pretentious one would from other hands. A sound philosopher, and a successful experimenter in his own particular science, he makes us feel that he hands us down a name worthy to consort with those who have gone before him.

"Notes for Chemical Students" is no more than what is expressed by the title. All minute description or details of experiments are excluded. It is an outline of the science drawn on the broadest plan, but with the most careful regard to definitions—it is, in fact, a book of reaction formulæ illustrating the principles of the science. The author also uses extensively a system of graphically portraying the chemical changes by circles (something in the same method as that used by Dalton) and bonds. The circles represent atoms, whilst the bonds represent the mode of attachment. "My aim," says the author, "has been to classify and systematise rather than to describe, and I have endeavoured to furnish the student with a kind of skeleton of the science, which it is intended he should himself clothe with the already known and daily increasing facts of experimental research."

Of the practical use of this book to students for the next five or six years we have some doubts, except for the author's immediate class, and a few more teachers who are prepared to adopt at once all the extreme views of Cannizzaro and some others. The book is written in a masterly style—*i.e.*, by one who has evidently his profession at his fingers' ends—yet in a terse and even elegant language. Thus how seldom do you find a correct definition of the science itself given? In that deservedly veteran favourite, *Fownes' Manual*, the author opened with a description of the science of chemistry, which would include every known branch of the physical sciences. The definition of chemistry is, according to Frankland, "the science which treats of the atomic composition of bodies and of those changes in matter which result from an alteration in the relative position of atoms;" and in the same pithy and clear manner the elements of the science are unfolded.

The author makes a determined stand against unsystematic nomenclature (Chap. 2); and whilst heartily concurring with his views in this respect, we see innumerable difficulties in the way. There are many of the trivial or irregular names so associated with uses in the arts that the substitution of others will not be generally adopted—*e.g.*, "hydric oxide" will never replace "water." Another cause of the feeling that militates against the systematic names proposed is their want of euphony—thus hydric-carbide, for marsh gas, is not very elegant, and hexapotassic-diferic-dodecacyanide (ferricyanide of potassium) is certainly stilted.

The author, with the assistance of Mr. H. McLeod, has been at some considerable trouble in drawing out the most important family of minerals under their systematic name, in connection with their graphic formulæ. In this case the graphic formulæ is most invaluable; but the systematic nomenclature cannot practically be used here, as the chemi-

cal composition in mineralogy is subservient to the physical characteristics.

The physical part is disposed of in a few pages, by giving the measures of weight, capacity, heat, and a description of the crith, or standard multiple (0.0896 gramme), proposed by Dr. Hofmann, for the conversion of gaseous volume into weight. The atomicities of the elements (so called) are explained by the bonds in graphic formulæ, or by dashes, &c. In the glyptic formulæ the use of the latter is particularly seen, when we get into the second division, or organic chemistry, in which the number of elements employed in the construction of the numerous compounds is so small, yet the number of their molecules is so great.

We would wish to go further into this important subject, but that space forbids. Although written for the student, it is in our opinion a work that will not be used by the tyro, not from any want of perspicuity, but from the fact that it is in advance of the chemistry at present taught in most of the schools; but it is a book that should be in the hands of every proficient of the science, whatever views he may hold himself. We are of opinion that this work will deservedly add to the fame of the author. C. R. C. T.

CHEMISTRY FOR STUDENTS. By A. W. WILLIAMSON, F.R.S., F.C.S., Oxford. Clarendon Press.

DR. WILLIAMSON'S book, as a whole, is a very dissimilar one to the above, yet it has some points of resemblance, *viz.*: It is a book intended for the student, framed upon the latest theories as regards the equivalents. Dr. Williamson's splendid researches, published many years since in connection with the molecular construction of the ethers, did much towards the establishment of the new views, and a manual from his pen should constitute a fitting introduction to the science to those who wish to adopt them.

We, however, would prefer that the work had been constructed upon a more logical method by first enunciating the broad principles of the science. The author adopts an entirely different plan. He opens with a description of the most important element—oxygen, then hydrogen. This naturally leads to water, and at this point the work is interlarded with three or four chapters on Physics—*i.e.*, latent heat of expansion, specific heat of water, &c. Then comes Chemical Notation (Chap. 5), and at the 13th Chapter, the Atomic Theory.

But the author had been previously describing decompositions, and opens his book with "Oxygen ( $O_2, O = 16$ )." What is the student supposed to know of " $(O_2, O = 16)$ ," or " $H_2O$ " before he learns the atomic theory? The author's reason for doing this is, perhaps, best explained in his own words, but we do not admire it. He says:—

"The method of exposition differs from that which is adopted in most other treatises of chemistry, for I describe and compare individual facts, so as to lead the mind of the reader towards general principles, instead of stating the general principles first and then proceeding to illustrate them by details."

Again, we think that too little importance is attached to the points connected with decomposition and construction, analyses and synthesis. The descriptions of them, the elements of the science being meagre, whilst the space devoted to the physical description is much greater than what is wanted in so small a manual. The author uses a table of elements, the equivalents of which are similar to those used by Cannizzaro, &c. He has a primary division into elements of uneven and even atomicity, and subdivisions into monads, dyads, triads, tetrads, &c. C. R. C. T.

CLINICAL MEMOIRS ON THE DISEASES OF WOMEN. By GUSTAVE BERNUTZ, Physician to La Pitié; and ERNEST GOUPIL, late Physician to the Bureau Central. Vol. I. Translated and edited by ALFRED MEADOWS, M.D., &c. 8vo. Published for the New Sydenham Society. 1866.

THIS volume is a translation, and in part a condensation, of the first part of the "*Clinique Médicale sur les Maladies des Femmes*," published by Messrs. Bernutz and Goupil, in 1860. The number of pages in the translation is less by half than the number in the original work; and we have the authority of the editor for saying that, while the translation has been abridged, in compliance with the instructions of the Council of the Sydenham Society, "the process of con-

denation has been principally restricted to the cases and notes;" the text has been given as fully as the space at Dr. Meadows' disposal would admit of. The general arrangement as to chapters and sections has been modified, with the view of making the work somewhat English in character; and the foreign weights and measures mentioned in the original have been reduced to our English standards.

As to the original work of Messrs. Bernutz and Goupil, it may be remarked that it is not a dogmatic treatise on the diseases of women, but merely a collection of clinical memoirs, as its title indicates. We have nothing to do with the character of the book itself; and we may observe that while the translation has been faithfully done, the notes bear the impress of want of accuracy, respecting which the reader need not go farther than the first page to see that ordinary care in revising the proofs would have prevented the defects here mentioned. This must not, however, be held in any wise to detract from the merit of the book itself, or from the fidelity of the translation.

#### LETT'S DIARIES FOR 1867.

THE circulation of these annuals nearly reaches 300,000, and we understand that it steadily increases in each successive year. The diaries are adapted to all classes of the public—some being peculiarly suitable for medical men—and they contain a great amount of miscellaneous information besides the usual almanac. The estimation in which they are held has been proved not only by their extensive sale, but by the fact that three prize medals have been awarded to them—one respectively in London, Dublin, and Oporto.

THE PRINCIPAL BATHS OF FRANCE; considered with reference to their Remedial Efficacy in Chronic Disease. By EDWIN LEE, M.D. Fourth Edition. Rewritten, with Additions. Pp. 154. London: Churchill and Sons. 1866.

HOMŒOPATHY AND HYDROPATHY impartially appreciated, with Notes Illustrative of the Influence of the Mind on the Body. By EDWIN LEE, M.D. Fourth Edition. Re-issued. With Supplementary Remarks on Homœopathy. Pp. 158. London: Churchill and Sons. 1866.

ANIMAL MAGNETISM AND MAGNETIC LUCID SOMNAMBULISM. By EDWIN LEE. Pp. 334. London: Longmans. 1866.

The number and variety of Dr. Lee's books testify alike to the versatility of his knowledge and the activity of his pen. The three volumes before us are on the most different subjects, and yet they all display a great amount of industry in their composition and of ability with which the topics are handled. The little work on "The Baths of France" is probably already well known as a useful guide to the celebrated watering-places of that country, and the present edition contains such additional information as the author has gained from personal visits to the spots described.

The book on Homœopathy and Hydropathy, which has also gone through several previous editions, contains a very able criticism and denunciation of the first form of quackery, and a just appreciation of the merits of the system of Priessnitz, which, within proper limits, is useful enough as an adjunct to other medical treatment. In his book on Animal Magnetism, Dr. Lee avows himself a believer in the phenomena which have been included under that term, and those who are curious on the subject will find it treated at length in his pages.

REFLECTIONS ON CHOLERA. By ALEXANDER HAMILTON HOWE, M.D. London: Hardwicke. 1866.

CHOLERA: ITS CAUSE AND CURE. By JOSEPH WALLACE, M.D. Belfast: Magill. 1866.

THE first of these pamphlets is an epidemiological tractate written by a member of the Epidemiological Society, and addressed to the public. It is one of the many attempts made to stay the plague by advocating sanitary and hygienic prevention. Dr. Wallace advocates a sort of homœopathic treatment. His "specific remedy" is *Coffea Cruda*, a tincture of raw Mocha coffee, respecting which he gives directions for preparation and use in small doses of from three to ten drops.

Dr. Wallace concludes thus:—"Let those, therefore, who desire to be known as true physicians, give my specific a fair trial, and they will reap more benefit than they can hope to gain by holding private meetings to organise a plan to prevent the public from deriving that benefit from my discoveries which they are calculated to give."

The italics are Dr. Wallace's own; and the specimen of his pamphlet is, we are happy to say, peculiarly his own also. To our readers we merely say, "*ex uno disce omnia.*"

#### CURRENT LITERATURE.

UNDER this title we propose, from time to time, to notice not only periodicals and pamphlets of passing interest, but a number of publications which we cannot find space to criticise at length. Here, also, we shall have the opportunity of mentioning, at an early date after their appearance, certain other important works to which we shall afterwards accord a more extended review. By this means we may further, perhaps, dispense with the usual notices of books received.

To begin then: Amongst the periodicals we may, at the commencement of the new year, congratulate some of our contemporaries on the manner their last volumes have been conducted. Of these we have the *American Journal of Medical Sciences*, and the *New York Medical Journal*, both of which have maintained the reputation of American scholarship. It is almost invidious to select papers, but we name, as especially interesting in the former, Dr. Hart's paper on Inhalations of Atomized Fluids; and in the latter, Professor Flint's, on the use of the Thermometer in Diagnosis and Prognosis. These are merely mentioned on account of the recent investigation of the subject, showing that Brother Jonathan is quite abreast with us—a fact to be gleaned from many other American journals, which we would gladly particularise, including the *Cincinnati*, *Chicago*, *Buffalo*, *Richmond*, *Savannah*, and some others which have reached us at intervals, and which we shall be glad to receive regularly.

In our own Colonies we are glad to find the *Canada Medical Journal*, the *Madras Quarterly*, and some others still flourish. To these we shall recur shortly.

As to our home journals, English, Irish, and Scotch, we have so often given each a separate notice that we may fairly omit them on this occasion. The impossibility of summing up our own periodical medical literature readily explains why we do not enumerate the many foreign journals we have received. In return for each we have forwarded our own in exchange, and take this opportunity of announcing our willingness thus to reciprocate with all our contemporaries at home and abroad.

We now turn to other publications. There has been for some time lying upon our table "*Sanitary Measures and their Results*," by Thomas Shapter, M.D., F.R.C.P., containing so excellent an epitome of what has been done, and with what effect, in Exeter, that we have only been waiting from week to week for space to furnish a full abstract. We must, however, delay no longer to commend Dr. Shapter's concise statements of facts to the earnest attention of all interested in the subject. On an allied topic we have also for some time had Mr. Sanderson's useful "*Suggestions respecting the Present Cholera Epidemic.*" Mr. Sanderson is a well known engineer, and eloquently urges his views respecting the drainage and water supply of the metropolis, and the reclamation of East London from dirt and disease to a sanitary state, worthy of our civilization.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 2, 1867.

### CLITORIDECTOMY.

It is not without a feeling of the greatest reluctance that we allude to the discussion now going on in profession circles on the subject of Clitoridectomy, an operation which is proclaimed by some as constituting a new era in the treatment of some diseases of females, and is condemned by many others as being not only useless but mischievous. For some months the efficacy of Clitoridectomy in some very serious diseases—as epilepsy, hysteria, and even insanity—has been loudly extolled, and even the columns of the "Times" have given currency to the favourable reports which have been made as to its success. But it must be admitted that these outbursts of commendation have been, to say the least, premature; for, independently of objections that may be made on other grounds, the new operation has not yet been adequately tested, in order to enable Practitioners of Medicine and Surgery to determine its real merits, and until this has been done it is somewhat injudicious to introduce the subject to the general public. In the meantime a host of objections, physiological, pathological, practical, and moral, have been offered to the proceeding by many who are capable of judging, and we must confess that many of these objections appear to us to have very great weight. In the first place, it is not at all clear that such diseases as epilepsy, hysteria, and insanity are in any way caused by functional or organic disease of the clitoris, and it is equally doubtful whether certain practices which are said to cause the diseases referred to are not rather the consequences than the cause. Again, we doubt whether the practices in question are really prevalent among the females of the present age, even if they were ever prevalent at all, at least to such an extent as seems to be assumed by the advocates of Clitoridectomy. Nor is it clear that even if the organ be removed, will the vicious tendency be eradicated. In opposition, too, to the statements made by Mr. BAKER BROWN, who is the great advocate of Clitoridectomy, as to its success, there are many counter-statements, alleging that it has entirely failed in the treatment of the diseases for which it is said to be specially adapted. In the controversy which has sprung up, much personal feeling has been displayed, and charges and counter-charges of mendacity have been somewhat unsparingly brought by both sides; but however disagreeable the subject may be, we hope that it will not be

allowed to drop until the Profession have been enabled to pronounce an authoritative opinion upon the points now submitted for its judgment. For the reasons we have above rather hinted at than fully explained, our own opinions are rather adverse to the operation, unless, perhaps, in some special cases, and after full consultation.

### THE NEW PHASE OF HOMŒOPATHY.

FROM certain indications of what is floating about on the surface of homœopathic literature, it would appear that the votaries of HAHNEMANN are beginning to distrust their idol, and to suspect that, after all, he made a great number of egregious mistakes. Not only is it doubted whether there is any force in his later assertions, that the smelling, or "olfaction" of such inert substances as chalk or flint, has an appreciable influence on the bodily organs, but he himself is admitted, by some of his own followers, to have been an arbitrary dogmatist and a scientific despot, with a dash of fanaticism, and a great deal of sectarianism and censoriousness. Now, this is pretty nearly the character given of him by those who disbelieve his dogmas, and if the believers in homœopathy attribute to him the same mental peculiarities, it is very probable that, as both parties are agreed, they are, in this respect, in the right. The fact is, everybody admits that he was a laborious investigator and a persistent defender of what he believed to be important truths; but then these supposed truths, when submitted to the test of experience, have turned out to be little more than unsubstantial visions, possessing, however, just so much substratum of facts as to redeem them from utter absurdity. Even the faith of the homœopathists in the infinitesimal globules begins to be shaken, and we are gravely told by one of their writers that there may be "cases in which pain must be relieved by opium; poisons must be removed by emetics; and perhaps, in wounds of the intestines, the parts must be kept at rest by large doses of opium." Why, if the homœopathists admit all this, they admit almost everything, for *if* pain is to be relieved by opium, and *if*, as many of the sect allow, castor-oil is to be administered in constipation, and *if*, as we have seen reported in their own journals, cod-liver oil and iodine are employed in scrofula (and these, be it observed, not in infinitesimal but in the usual doses), then the whole question at issue between what they call, in their absurd jargon, homœopathy and allopathy, collapses into nothingness. Many diseases, as is well known, will terminate, if left to themselves, in a spontaneous cure, and others will remain incurable, or will terminate in death, in spite of all treatment, and the homœopathists deserve no credit for the cure of the former cases, and no blame for the results of the

latter. Where they are blameable, and most justly so, is for their arrogance and presumption in pretending that the administration of inert infinitesimal globules has any influence whatever in arresting the progress of disease, or in correcting the effects of a more rational, though it may be, unsuccessful practice.

But, as we have observed, a new phase is developing itself in the position of the homœopathic doctrines. We are now told authoritatively that "homœopathy does not consist in giving medicines in infinitesimal doses, and so testify all who practise homœopathically," and then we are gravely referred to the etymology of the word, invented by HAHNEMANN for the name of his system, as if nobody understood Greek except a few of the homœopathists themselves. No elaborate argument is required to prove that the doctrine of *similia similibus curantur* (the rather barbarous Latin of "like cures like") is to a certain extent, and in a limited number of instances, founded on facts; but then the objection is fairly made that most of the instances brought forward as facts by HAHNEMANN are not facts at all, being founded on such a scanty number of experiments as to divest them of all scientific value or significance. It is true, for instance, that vaccinia, which bears a certain resemblance to small-pox, will, by inoculation in the system, prevent in most instances the latter disease; but it is *not* true that belladonna will cause scarlet fever, and it is not proved that it will either prevent or cure it. Again, it is true that the application of a blister which causes an external inflammation will often help to cure an internal one; but it is *not* true that quinine, although it will cure an ague, will ever cause one. It is mere idle sophistry to compare the headache, and the other slight feverish symptoms sometimes caused by an overdose or an improperly administered dose of quinine, with the regularly recurring paroxysms of an intermittent. Once more, if there were any truth in the universality of the law of *similia similibus*, the cure of an ague should be effected by placing or leaving the patient in the marshy district which produced the disease, whereas all common sense and common experience, and we may add common humanity, point to a precisely contrary plan.

If, then, the homœopathists give up the infinitesimal globules, and rely upon the doctrine of *similia similibus*, and if, moreover, they abandon their arrogant assumption of having made a wonderful discovery in medicine, there is some hope that they may secure a hearing for the few maxims of common sense which, amidst an infinitude of fallacy and verbosity, pervade their doctrines, but which, we may observe, were well known and adopted before the time of HAHNEMANN. At the same time it would be unfair to deny that the practice of the homœopathist

has read us the useful lesson that the *vis medicatrix nature* is of powerful efficacy in the treatment of diseases, and that the excessive or injudicious use of drugs is on all grounds to be deprecated.

#### THE REMUNERATION OF IRISH POOR-LAW OFFICERS FOR CHOLERA ATTENDANCE.

THE recent cholera epidemic has evoked from the Dispensary Medical Officers of Dublin an amount of self-sacrifice and labour in the discharge of their duties which deserves the attention and gratitude of the public. The late onset of the disease, though numerically of less importance than past epidemics, has been most virulent and fatal, and has, under Divine Providence, been undoubtedly stemmed in its progress by the Medical Officers of the city, and the efforts of Dr. MAPOTIER and the sanitary authorities. In almost every district the Medical Officers not only devoted unremitting attention at all times of the day to the unfortunates stricken down, but they left their home and families and in rotation remained all night in the Dispensaries watching for the call to hurry forth and battle with the fell contagion. We repeat the statement that the Dispensary Officers of Dublin have earned the gratitude of the public by a complete sacrifice of their comforts to a strong sense of duty, and by fearless exposure to danger, which none can appreciate better than they themselves. Nor have they escaped the natural consequences of exposure to cold, miasmata, and infection, for many of them have passed through severe attacks of choleraic diarrhœa, miasmatic fevers, and anthrax, and have dearly paid in their health for the immunity of the poor from disease.

The Medical Officers of Dublin have not bargained and sold their services in this crisis—they have met the demands of humanity without stinting it by their expectation of remuneration, and it is placed on the honour of the public and on their sense of grateful justice to show their appreciation of such services on a scale as liberal as the excessive duties have been. In most of the suburban districts, where the claims of duty, though sufficiently exacting, were much less so than in town, the Guardians have fairly and honourably met the occasion by a vote of one guinea per day to each medical man, and not even the most parsimonious of ratepayers will think that the *honorarium* was easily or inadequately earned. We regret to learn that in Dublin the fee named has been only ten-and-sixpence. We offer no reproach for the shabbiness of this remuneration, which we regard as a matter of secondary importance; but we simply ask the Guardians, which of them would discharge even a tithe of the duty for the sum proposed, and whether they consider that such an unjust parsimony will be an encouragement to

medical men to meet such labours, inconveniences, and dangers, on another occasion? It is but just to say that the Dublin Boards of Guardians have energetically and liberally battled with and crushed the epidemic, and it would be unworthy of them to act in a spirit of illiberality and unfairness to their officers, who have so disinterestedly carried out their instructions.

### THE HEALTH OF LONDON.

ACCORDING to the last return of the Registrar-General, the health of London continues to be good. During the 51st week of the year, which ended on the 22nd of December, the total mortality was 1377, which is 75 less than the estimated number for the corresponding week.

Two deaths from cholera and 16 from diarrhœa were registered during the week.

Twenty-six deaths from small-pox, 30 from scarlatina, 43 from whooping-cough, and 55 from fever were registered in the week.

Phthisis proved fatal to 178 persons; 171 deaths occurred from bronchitis, and 98 from pneumonia.

Five deaths were registered as resulting from injuries caused by horses or carriages in the streets, and 7 children died from burns or scalds.

The annual rate of mortality last week was 23 per 1000 in London, 29 in Edinburgh, and 24 in Dublin; 22 in Bristol, 21 in Birmingham, 33 in Liverpool, 32 in Manchester, 31 in Salford, 23 in Sheffield, 28 in Leeds, 20 in Hull, 34 in Newcastle-upon-Tyne, and 29 in Glasgow.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 30.11 in. The mean temperature of the air in the week was 41.3 deg., which is 2.0 deg. above the average of the same week in 50 years (as determined by Mr. Glaisher). The mean of the highest temperature of the water of the Thames was 42.4 deg.; that of the lowest was 41.1 deg. The difference between the mean dew-point temperature and the air temperature was 3.2 deg. The mean degree of humidity of the air was 89, complete saturation being represented by 100. Rain fell to the amount of 0.05 in. The general direction of the wind was south-west. According to a return furnished by the engineer of the Metropolitan Board of works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, was 207,543 cubic metres.\*

### Notes on Current Topics.

THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, LONDON.—We hope we are not premature in announcing a step in the right direction. The English College of Surgeons has made a communication to the sister College respecting the propriety of introducing some examination in medicine for the candidates for its diploma. The reply has been prompt and courteous, and the College of Physicians has appointed a committee to report on the sub-

ject. There ought to be no difficulty whatever about the matter. In this year of grace 1867 surely a termination can be put to the rivalries of our corporations. Otherwise it were well for the profession to remove them from the elevated position they have so long occupied, and hand over their privileges to institutions more in harmony with the times.

THE DANGERS OF CHRISTMAS BEEF.—A few years ago the lovers of good cheer were alarmed by statements to the effect that most of our prize oxen were the subjects of fatty degeneration, and that the bulk so much admired was in reality disease. More recently this has been denied, but all investigators are not satisfied. Pending the controversy, we beg to point out a far more easily demonstrable danger. In every street in London the butchers have recently displayed their Christmas beef gaily decorated with ribbons and rosettes. Now these ornaments are mostly fastened with pins, which if overlooked may give rise to sad accidents. Cooks are sometimes guilty of putting pins in meat, and there is another instance of thoughtlessness on the part of those through whose hands our food passes. The idea of one's meat being diseased is enough to destroy the appetite, but will make a less serious impression on many a mother than the danger of seeing her child left choked by a pin in its throat.

THE "PALL-MALL GAZETTE."—Some of our readers will, no doubt, sympathize with the proposal of an esteemed correspondent in our last number to raise a fund with which to express the gratitude of the profession for the spirited manner in which the *Pall-Mall Gazette* has defended our rights, and notably in the recent trial of *Hunter v. Sharpe*. A similar idea has also been started in another quarter, and there seems now to be little doubt that it will be carried out. For our own part, we firmly believe that the public is even more indebted than the profession to the journal in question. Whatever the merits of any particular case, English journalism will always defend the right to criticise proceedings in which the well-being of Society is involved, and we think that the defence of such rights is a matter of public interest. We trust, therefore, that subscriptions will not be confined to our own profession—by no means a rich one. We should be glad, indeed, to see the public sufficiently alive to the subject to raise money enough to put down every species of quackery that subsists on the fears of the suffering and the ignorant. We need only add that we shall be happy to acknowledge contributions in our columns, and in any other way co-operate in the movement.

A SMALL-POX WARD.—Four or five cases of *modified* small-pox occurred last month among the in-patients at King's College Hospital. The first patient had been in the hospital a fortnight when he was seized, and although he had been out twice during that time to see his relations, none of them were suffering from the disease, and the infection could not be traced. He was removed to the Small-pox Hospital, but when the two patients occupying beds on each side of him were afterwards seized, a ward was cleared to receive them. No new case has occurred for a fortnight. In none of the cases did the eruption

\* A cubic metre is equal in volume to 35.3174 cubic feet, or to 220.0967 imperial gallons. It is nearly equivalent to the old English "tun" of four hogsheds, or to 35.248 cubic feet. It is in general use on the Continent, and is a much better unit for measuring sewage or water supply than the gallon.

last beyond the sixth day; in some only to the fourth. All the patients had been vaccinated—all, in fact, had very distinct marks, and all suffered so slightly from the varioloid eruption, that the cases may be called trivial. Had they not been under medical surveillance for other diseases, the variola would probably have passed unnoticed. We have reason to believe that sometimes such mild cases as these occur, in which no medical advice is sought, and the patient only remembers "a little eruption," or a "few pimples."

**THE DIRECTOR-GENERALSHIP OF THE ARMY MEDICAL DEPARTMENT.**—The office of Director-General of the Army Medical Department will, it is understood, shortly become vacant, in consequence of the expiration of the term of office of Sir James Gibson. Speculation is already busy with the names of officers likely to succeed him, but all conjectures on the subject must at present be premature, because the present Director-General is eligible for reappointment, and the question with the Government will probably be merely one of finance, for if Sir James Gibson retires, he will be entitled to a retiring pension equal to his present salary, and there is already another former Director-General on the retired list. The position, the emoluments, the influence, and the patronage of the Director-General of the Army Medical Department have been very much altered of late years by the Government, and the occupant of the office has in reality very little power in comparison with some of his predecessors. Sir James MacGregor, who held the appointment for many years, had a salary of £2000 a year, and was absolute chief of the department, holding all the patronage in his hands, and regulating the promotions at his own will; but on his retirement the salary was cut down to £1200 a year, and the patronage was entirely abolished, and this somewhat unwise economy has probably been the cause of many of the shortcomings of the Army Medical Department. Sir Andrew Smith, in adopting the economical principles on which his own appointment was founded, endeavoured to introduce so many schemes of reduction that, as is well known, the whole machinery broke down, and he retired with a pension of £1500 a year, which is the present salary of the Director-General. It is only fair to state that Sir James Gibson, who is certainly rather unpopular with the Army Medical Officers, is not altogether responsible for the grievances so generally complained of, inasmuch as his influence is comparatively very much limited by the authorities at the Horse Guards.

**HYGIENE IN THE MERCANTILE MARINE.**—While the condition of the Royal Navy in respect to its sanitary regulations has been immensely improved of late years, that of the mercantile marine has been most unwarrantably neglected. The reason of the difference in these two branches of the public service is to be found in the circumstance that while the Royal Navy is governed by a central authority, the acts of which are jealously watched by the House of Commons and the public, the merchant service on the contrary is regulated by individual ship-owners, who are to a great extent irresponsible. Hence arises the prevalence of scurvy and other diseases in merchant vessels, while the health of the men in ships of war is unexceptionally good. It will be gratifying to the public to know that the whole subject of improving the

hygiene of the merchant service is occupying the close attention of the Government, and that it is proposed to introduce some measures in the next session of Parliament which will remedy many of the existing evils. The censures passed upon the shipowners apply of course only to exceptional cases, for many of those employers of labour conscientiously watch over the health of the crews whom they employ; but as in all other pursuits in life, there are persons who neglect their duties, and these will, by the contemplated legislation, be brought under the pale of the law.

## Proceedings of Societies.

### AN ADDRESS

DELIVERED BEFORE THE

SURGICAL SOCIETY OF IRELAND,

AT THE OPENING OF ITS THIRTY-SIXTH SESSION,

On December 8th, 1866,

By the President of the College, Dr. BUTCHER.

GENTLEMEN,—as President of the Royal College of Surgeons, I have the honour of addressing you to-night. We meet to inaugurate the Thirty-sixth Anniversary of the Surgical Society of Ireland. After the very able Address of Professor Jacob, at the opening of the Session of 1864, in which he detailed the entire constitution of the Society, from its very foundation in the year 1831, its rules, its bye-laws, the mode of election of its governing body, its council, and all its component parts, it would be superfluous to add one word on that subject. Again, the able and valuable Address of my distinguished predecessor, Dr. Wilmot, in which he eloquently spoke of the protective influence of the College of Surgeons, so freely and encouragingly extended to this Society, for the advancement of Medical and Surgical truth, leaves me nothing to say on that head. Some present may not be aware that, in the earlier years of this Society, members subscribed to defray the expenses incurred by its meetings; but for years back, the College of Surgeons has thrown its protective ægis over the Society, and admits all gentlemen elected to membership free. After the elaborate, comprehensive, and instructive addresses to which I have just referred, I have had some difficulty in finding matter for the Address which I have now the honour to deliver before you.

The advantages arising from such Societies as ours, it is not easy to over-estimate; indeed, these advantages are so generally recognized, that we find similar associations widely established both at home and abroad. They furnish the readiest means by which anything new, or otherwise interesting in medicine or surgery, may be communicated to the Profession, and be submitted at once to that thorough ventilation and searching scrutiny, whereby its real value may be tested and ascertained. In all subjects nearly affecting man's material well-being and happiness, it is of great importance that whatever professes to be a new discovery, or a new application of a truth or principle already known, or an improvement upon some method or practice hitherto received, should be carefully examined and its claims upon the attention of the public scrupulously investigated. This applies with especial force to subjects such as those with which we deal, directly affecting, as they do, man's health, his happiness, and his life itself.

In medicine and surgery much is known and much has been done. But they who have studied these most profoundly, and practised them most successfully, are best aware how much still remains to be known and done in both. Many questions which baffled the powers of the

great fathers of our profession centuries ago, still await their solution; and every day new questions are starting up, some of which wholly elude our grasp, while to others we are able to furnish only a partial answer. There is then a wide, and an ever-expanding field, in which the most refined observation, the keenest sagacity, the maturest judgment, and the subtlest analysis of the Physician and Surgeon have ample room to exercise themselves. With what success that field has been cultivated in recent times, and by our own schools in this city, it is almost unnecessary to state before this audience. Yet a few examples may not be uninteresting to elucidate this position; and there are two names which come prominently to my recollection as deserving of the honor. These men passed away too soon from amongst us; we can now recal their great merits, without any disparagement to the living.

You all remember the arduous, indefatigable labours of Houston, the able anatomist, the profound physiologist, the great surgeon; in the early years of this Society we find him ever foremost in the path of investigation, discovery, and truth; at the same time a large contributor to other societies and to the journals of the day. It is now twenty-six years ago since he laid before this Society a full analysis of Müller's great work on Malignant Diseases, and unravelled its difficulties for the benefit and attraction of others. I shall quote his own words, as he modestly speaks of himself, in the introduction to this communication:—"Müller led the way in these researches, many other able investigators are also in the field, and astonishing results are daily being brought to light. Being, myself, possessed of an acromatic microscope of high magnifying power, I have been endeavouring to follow in the wake of these pathologists, and to inform myself as to the accuracy and value of their statements. I have taken every opportunity to make myself acquainted with the microscopic characters of morbid growths; and the object of my present communication is to introduce the subject to this Society, and to exhibit some preparation from the museum, which I regard as illustrative of the several varieties of cancer." I need scarcely say how many able labourers, members of this Society, have since then worked and are still working in the same field of microscopic investigation, with credit to themselves and great benefit to science. We have in the records of this Society, and from the same hand, most valuable papers on anatomy, physiology, pathology, and practical surgery; but these would be too numerous to dwell upon. His name is indissolubly connected with what may be looked upon, I would say, as one of the glories of this College—its museum; here we have a perfect monument of his ability, his judgment, and his power. A glance at the hundreds of preparations stamped with his initials, prove his indefatigable industry, while a more close investigation of them shows his truthfulness in delineating nature's laws, and his perfect acquaintance with all the types of life; the catalogues, containing a description of this storehouse of knowledge, arranged by him, bear the strong impress of a master-hand, and, I trust, the College will before long place a bust of Houston in that museum where he so sedulously worked.

Another member, more recently removed by death, Bellingham, has left his name amongst us likewise imperishably recorded. The records of this Society bear ample testimony to his protecting guardianship. For years he was one of its honorary secretaries, and for years he was a large contributor of knowledge to its members. Numerous, indeed, were the communications which he brought forward both in medicine and surgery. I am certain that every member here will recollect his various interesting, able, and instructive papers on diseases of the heart, which ultimately were presented to the profession in the shape of a large volume. Accuracy of observation, tact in diagnosis, acumen in judgment, steadiness in practice, are all strongly stamped upon the pages of this book. It is, however, with the subject of the treatment of aneurism by compression that this Society

and the Surgical School of Ireland will most gratefully remember his name with great honor. His views, his reasonings, and his practice upon this problem were conclusive, as to its solution and adoption. Worthily has his bust been placed in the hall of this College. And I fully subscribe to the opinion of Professor Jacob, as expressed a short time ago in his address from this chair:—"I can safely say, his labours in this Society were the principal cause of his having that testimonial erected to his abilities, his industry, and his zealous labours, in the College."

My immediate object now, in connection with the utility of such societies as this, is to insist on the importance of having each alleged discovery in the theory or practice of medicine, each new operation or mode of treatment in surgery, or proposed modification of the received methods, submitted to the calm judgment of those who may be presumed to be best qualified to decide upon their real value, and who will freely and honestly pronounce their opinion about them. The objections which they urge, the difficulties which they raise, the suggestions which they offer, will all tend to the further development and more complete elaboration of the discovery or invention, if it be really valuable. We all know how liable a man is, especially if he be of an enthusiastic temperament, to be biassed in favour of any theory which he has himself constructed, any conclusion which he has adopted after a long and laborious course of investigation. The theory may be purely fanciful, or rest on insufficient induction; the conclusion may be derived from false premises, or vitiated by illogical reasoning; still, the man himself, prejudiced in favour of what has cost him much thought and time, flatters his eyes against all but what he desires to see, and shuts himself that he has done some great thing. Men of our profession are of course not exempt from this common weakness of which I speak. And, therefore, it is well that our supposed discoveries, reasonings, inferences, and methods of procedure, should be minutely criticised, thoroughly sifted, and carefully tested. A fair, manly, straightforward discussion, conducted in the spirit of philosophical inquiry, and animated by the sincere love of truth, will act like the refiner's fire. If there be genuine ore it will come out the more pure when separated from the dross with which it was mingled; if there be none, the process will show that there is none; and however the individual may be mortified, the interests of truth will be served.

These are the principles on which this Society was originally founded, by which it has hitherto been guided, and which will, I trust, continue ever to prevail in its deliberations and debates. Charged with the high and responsible functions that we are, we will never, I am sure, suffer a mean rivalry or paltry jealousy to prevent us from cordially recognising and approving anything, whether in the way of theory or practice, which really tends to enlarge the boundary of our knowledge, to systematize what we already know, or to improve our received methods of procedure. There are difficulties and discouragements enough to be encountered by any one who earnestly devotes himself to such a task, without the paralysing influences arising from envious disparagement and ungenerous detraction. May the animating spirit of this and similar associations ever be to cheer and aid the labourer in his work, and ungrudgingly to award that meed of praise which his services in the cause of truth seem fairly to deserve! We must be contented often to labour long and patiently before achieving any great or striking result. The phenomena with which we have to deal, involving all the mysterious agencies of that subtle principle of *life*, whose nature eludes our keenest scrutiny, are infinitely diversified, and for the most part so complicated as to resist the efforts of the most searching analysis to reduce them to their simple elements. General laws, the applicability of which to particular cases may safely be relied on, are with us but few; and in many departments of our science there are as yet none worth the name. What, for example, do we know

of the laws by which epidemics are propagated? Shall we ever be enabled to predict the occurrence of a pestilence with that certainty with which astronomy foretold the re-appearance of those meteors whose brilliancy, a few nights since, lighted up our skies? The conditions of the problem in the one case are all definite and known; in the other the conditions are unknown, and moreover are perpetually changing. But, however this may be, we have still a boundless field before us. Each of us, individually, may do something towards the cultivation of it by patient labour and careful observation, but infinitely more may be done by combined effort and mutual co-operation. This is the fundamental principle of all Associations, as it is of ours. No man is able to bestow minute attention on every department of medical and surgical science, so as to be an equally great authority—an equally eminent writer—on all alike. The range of subjects is too vast for this. Profound knowledge requires concentrated attention and long study. Nor can the same individual strike out and tread many paths of original discovery. Hence the necessity on the one hand of division of labour, so as to get each portion of the entire work more perfectly done; and, on the other hand, of bringing together the various constituent parts, so as to combine them all into one grand harmonious whole. This synthetic process it is the main business of such societies as this to accomplish. To be a great physician or a great surgeon falls to the lot of but few. It requires a number of qualities rare in themselves, and still more rare in combination with each other. Keen observation, fine tact, intuitive sagacity, readiness in resources, boldness in conception, skilfulness in execution, a clear and cool head, a firm and delicate hand—these and other qualifications, which mark the foremost men in medicine and surgery, are natural gifts, and cannot be acquired. But while it is not given to all to be great, there is none who cannot, by earnest, patient work, contribute something to the general stock of our knowledge. Let us, then, labour energetically, each in his own particular sphere; but let us also remember that we are members of a body banded together for the attainment of a common end, and that the best means of attaining it is by united effort and cordial co-operation. It was thus that this Society has already done so much for the advancement of medicine and surgery, and that it now enjoys the prestige of a high name among the scientific Associations of our country.

Be it ours to emulate the labours of those who have gone before us. And when we commit this Society to our successors, may we have the satisfaction of knowing that its reputation is at least as high, and its usefulness at least as great, as when it came into our hands.

**STRICTURE OF THE URETHRA ABOUT FOUR INCHES FROM THE MEATUS; SUPPRESSION OF URINE; FATAL COMA.**

MR. B. WILLS RICHARDSON brought under the notice of the Society a specimen of stricture of the urethra, apparently the result of gonorrhœa contracted some years previously.

The patient, George Valentine, 52 years of age, from whose body the specimen was taken, was admitted into the Adelaide Hospital at four o'clock P.M. on the 17th of last month, having been recommended to him by his friend Dr. Dockeray of Kiltegan, in the county of Wicklow. I should mention, however, that Dr. Dockeray did not see the patient for a few days previously to his leaving the country to come to hospital, and therefore before symptoms of suppression of urine set in.

Valentine, on being questioned, stated he had not passed any water to signify for some hours; and as he had suffered from retention of urine on various occasions, of which retention he was relieved by Dr. Dockeray, he thought he was similarly affected on the 17th, and redoubled his exertions to get into hospital. In this belief, however, as I shall now mention, he and his friends were in error.

On inquiring about his symptoms, it was ascertained that he passed a couple of drachms of urine a short time after his admission into hospital; but he had no urgent sensation for voiding water, nor straining to do so. Nothing like a distended bladder could be discovered in the hypogastrium;

indeed, the abdomen was quite clear to percussion in this region. He, however, complained of deep pain in the true pelvis, and, curious enough, as the sequel will show, he was not tender to pressure in the locality of the bladder.

The small quantity of urine, first alluded to, having been examined, was found to be somewhat whey-like in appearance, and so albuminous that it became semi-solid on the addition of a few drops of nitric acid, much more so than could, he (Mr. Richardson) thought, be explained by the small quantity of pus present in it.

The pulse was slow and laboured; the skin cool, and he was drowsy, and had to be roused in order to get a satisfactory answer from him; the tongue was dry and brown, and the bowels were constipated. We were told by his friends that he never, to their knowledge, had a convulsion, nor was he ever dropsical.

An exploration was made of the urethra, and it was found that the bougie was stopped at about four inches from the orifice.

As it was evident that there was no urine of any account in the bladder, and when we recollected the highly albuminous state of the small quantity of this fluid we were so fortunate to procure, we had no hesitation in concluding that Valentine's kidneys were diseased, and that probably the suppression would be complete in a few hours, and a fatal result would be the consequence.

He was ordered some purgative medicine, but no attempt was made to stimulate the kidneys.

On the 18th, although the bowels were well freed, he was more stupid and somnolent; the pulse was more laboured, and he passed but a few drops of urine. There was no evidence of distended bladder.

On the 19th no urine at all was passed, and he was evidently lapsing into coma, which was complete on the 20th, and he died at half-past eight o'clock, A.M.

The penis, bladder, and kidneys having been removed from the body, the urethra was first carefully examined, when a very tight stricture was found about four inches from the orifice, which the members would see when the preparation was handed round. The stricture is about an eighth of an inch long, having its canal in the centre. Immediately after death it permitted the passage of a very small No. 1 catheter, but at present, owing to the action of spirit, a very small wire can only be got through it. No other stricture existed in the urethra. The bladder is very much contracted, exceedingly thickened, and its mucous membrane when first examined, was of a greenish slate colour. There was about a drachm of whey-like fluid found in it when opened.

The left ureter was very slightly enlarged; the right duct was about its normal calibre.

The kidneys I have not here this evening, as I wished to inject them if possible. In this attempt I completely failed, they were so extremely degenerated and loaded with oil. The injection I used was a modification of Dr. Beale's Prussian blue fluid, and although I did not try the injection until about the time the post-mortem contraction of the vessels should have ceased, I could scarcely get any of the blue fluid into the vessels of the critical structure. Very few malpighian bodies were injected, but I was so fortunate as to get one or two perfect specimens of well filled efferent vessels, which I attribute to the pressure of the morbid deposit in the critical structure, directing as it were, the injection into a few permeable *tasa efferentia*.

On examining portions of the critical structure under the microscope, large quantities of oil globules were discovered, both free between the tubes and also in these ducts themselves. The epithelium was also granular, apparently from the presence of oil. He Mr. (R.) considered the kidneys excellent specimens of fatty degenerated glands. They had not the appearance of diseased kidneys, the mere result of stricture of the urethra, but were good examples of one of the forms of Bright's disease.

The cranium was not examined, but he thought it might be safely assumed that the coma in this case was renal and the result of the pathological changes he had first mentioned.

**COMPOUND AND COMPLETE DISLOCATION OF THE ASTRAGULUS—IMMEDIATE REDUCTION OF THE DISLOCATION—COMPLETE RECOVERY, WITH PERFECT MOTION OF THE ANKLE-JOINT.**

DR. FLEMING detailed a case of the above complicated injury, and alluded to his former communication to the Society on

the same subjects. He particularly noted the case of Dr. Hadden of Clonakilty, Co. Cork, published immediately afterwards in THE MEDICAL PRESS AND CIRCULAR. He considered it a case extremely creditable to the promptness of act and the superior judgment of Dr. Hadden. Through his kindness Dr. Fleming was enabled to place before the Society the fragmentary portions of the astragalus which had been removed at the time of the accident, placed *in situ*, and temporarily secured so by Dr. Barker. They constituted the whole of the astragalus. Dr. Fleming read an extract from a letter of Dr. Hadden, in which it was stated that the woman, the subject of the case, had fully recovered with a most useful joint. The subject of the case under the notice of the Society was exhibited to the members. He was a man of middle age, and had ankylosis of the knee-joint corresponding with the injury, permanently good in the extended position. Although less than two months had elapsed since the accident, the large accompanying wound had fully healed, and the motions of the joint were perfect.

DESCRIPTION OF A CASE OF CONGENITAL DISLOCATION OF BOTH WRIST-JOINTS AND RIGHT KNEE-JOINT.

By Dr. CROLY.

James Collier, aged 78 years; about five feet six inches in height; a weaver by trade; is married and has children; does not know of any congenital malformation having existed in any member of his family.

*Right Elbow-joint.*—Flexion and extension perfect; supination cannot be carried beyond the mid-point between the prone and supine position; pronation nearly perfect; radius and ulna slightly curved, the latter forming the arc of a larger circle than the former; the carpus with the hand is displaced backwards, and the hand can be carried backwards to a right angle with the forearm; the lower extremity of the ulna projects forwards and inwards, and apparently unites by its outer and posterior aspect in articulation with the bones of the carpus; the lower end of the radius projects slightly forwards and the hand is thrown outwards; considerable effusion into the carpal bursa, forming a mid-prominence in front of the wrist.

The measurements of the right arm:—From acromion process to olecranon, the forearm—the lower extremity of fourteen inches; radius, five and a quarter inches; ulna, seven and a quarter inches; hand, six and three-quarter inches.

*Left Elbow-joint.*—Flexion and extension perfect; no pronation or supination allowed; the ulna projects backwards at its carpal end, its articular facette apparently on its anterior surface; the radius projects slightly backwards, and the hand is inclined outwards; much less lateral motion in the wrist-joint of the left than at the right side.

*The Right Knee-joint* displays a congenital luxation of the head of the fibula, which projects backwards and outwards; the tendon of the biceps projects prominently beneath the skin at the outer side of the popliteal space; the right fibula measured thirteen inches, while the left one was only eleven inches and a quarter.

Left arm measured fourteen inches from acromion to olecranon; left radius six inches along the convexity of the arc; chord of arc, five inches; ulna measured eight inches; hand seven inches.

DISLOCATION BACKWARDS OF THE SECOND PHALANX OF THE THUMB.

DR. STAPLETON wished to bring under the notice of the Society a mode of reducing dislocation of the thumb by manipulation, and without the use of lacs, forceps, or any other of the ordinary appliances.

The patient, a woman about forty-five years of age, returning home about nine o'clock on Saturday night last, tripped and fell, the end of the thumb coming into contact with the ground. When she raised herself, she felt extremely faint from the pain, and believed she only sprained her thumb; the pain continuing severe, she sought relief at Jervis-street Hospital, and as he (Dr. Stapleton) happened to be at the time in the hospital, he at once recognised the nature of the accident, and explained it to the class.

Having heard from Mr. Ledwich of his having successfully reduced a similar dislocation, the usual plans having failed, he (Mr. Stapleton), by placing the edge of a table in

the angle formed between the thumb and index finger, the thumb being upwards and resting on its palmar surface, the hand being steadied by an assistant, he pressed the prominent displaced end of the phalanx horizontally forward with the ends of both his thumbs, while with his forefingers he raised the distal extremity of the luxated phalanx, when, in about half a minute, reduction was effected. Chloroform was not administered.

HARVEIAN SOCIETY OF LONDON.

15TH NOVEMBER, 1866.

President—Dr. THOMAS BALLARD.

DR. H. C. STEWART read a Paper on a

CASE OF EMBOLON OF LARGE VESSELS.

Upon two former occasions he had had the honour to read before this Society papers upon "Fibrinous Concretions, or Plugs formed in the Heart, and Great Vessels leading thereto and therefrom." He produced before the Society, this evening, a patient, who, on the 29th October last, came to him seeking relief from bronchitis, and who presented prominent symptoms of a fibrinous deposit slowly taking place in the vena cava superior, and probably extending into the right auricle.

Robert L., æt. 59, married, a labourer in a timber yard, has lived freely in former years but not lately, and has never had rheumatism. He caught cold about three weeks before Dr. Stewart saw him, and took several home remedies, but had not applied for medical advice until now. Complaints of chillness, difficulty of breathing, with cough and a copious expectoration; has thirst; tongue slightly furred; bowels constipated; urine scanty and dark-coloured; pulse 96, weak; his lips, nose, cheeks, and ears are of a deep purple colour, and slightly colder than the surrounding parts; general appearance of skin of face and neck deeper coloured than usual; veins of the neck, particularly the jugulars and superficial veins of the chest, enlarged, prominent, and varicose; chest abnormally flattened from before backwards; movements of the chest normal; percussion notes resonant; coarse crackling heard over the greater part of both lungs, particularly the right; slightly-increased impulse with the heart's beat; its rhythm irregular; there is a slight blowing sound or auricular-systolic murmur over the right auricle preceding apex beat.

We cannot, said Dr. Stewart, have any great difficulty in reading this case, when we remember that the venous blood from the parieties of the chest and vertebral column is returned to the heart through the medium of the *venæ azygos (major et minor)*, and the superior intercostal vein; the former opening into the vena cava superior immediately over the right bronchus; the latter into the left vena innominata. Any obstruction to the circulation in the vena cava superior would be evidenced by an enlargement of the superficial veins of the chest and neck, as in this case, and produce cyanosis of the lips, cheeks, nose, and ears. For the original cause we must look to his previous life, which was what is called "free," in other words "drunken." No doubt his abnormally-flattened chest may have contributed somewhat to produce disease, by diminishing the internal space required for the healthy performance of the functions of the chest; and lastly, his mode of gaining a livelihood, that of labourer in a timber yard, where he is frequently called upon to carry very heavy loads upon his shoulders.

Since this examination was made he has been relieved of his bronchitis, and is altogether in better health.

Dr. Cock said there was not time to go into the case; but he doubted the inference drawn by the author of the paper, from the symptoms.

Mr. SEDGWICK was rather inclined to attribute the cyanosis, &c., to the consequences of some inflammatory condition of the lungs, than to take the view the author did of it.

THE "Gazette de France" states that Madame Pillaud has just died at Bergerac (Dordogne) at the age of 105 years. Her son, a priest 80 years old, read the funeral service over her.

## Foreign Medical Literature.

### A CASE OF CONGENITAL MALFORMATION OF THE HEART.

By J. F. BAERKEN, Leyden, 1865.

Selections from the *Nederlandsch Archief voor Genees- en Natuurkunde*, Deel ii. 2e Afl. Utrecht, 1866.

Translated by W. D. MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS; OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

IN the first chapter of his work, the author communicates the history of the case, and the anatomical description of the heart. The child in whom the abnormal heart was found died five weeks after birth, with cyanotic symptoms, dyspnoea, diarrhoea, &c. The impulse of the heart was very strong.

On opening the body the heart was found much enlarged; seen from before it had about the form of an equilateral triangle. The posterior surface was reniform. There was no auricular septum; only on the anterior wall did a large musculus pectinatus indicate a trace of partition. Close to a right, well-formed auricula a vena cava superior dextra opened, and immediately adjoining it two pulmonary veins entered from the right lung. In the left division of the auricle were the openings of a vena cava superior sinistra and two pulmonary veins. The left auricula was well formed. On the posterior wall of the auricle the two mouths of two venae cavæ superiores were found.

There were two ventricles separated by a perfect ventricular septum. The cavity of the ventricle lying to the right was small, and its walls were slight. The artery issuing from this ventricle curved backwards over the right bronchus; in its course and ramification it corresponded to the aorta. After being joined by the still completely open and wide ductus Botalli from the pulmonary artery, it became much thicker than it was at its origin. From the left ventricle proceeded an artery, completely corresponding to the pulmonary artery, dividing into a branch for each lung and the ductus Botalli.

In the second chapter the author gives a short sketch of the normal development of the heart, and comes to the conclusion that our knowledge is not yet sufficiently advanced to explain deviations such as that now described. That at the time of the formation of the partition in normal cases, a torsion of the heart from left to right takes place, is very certain. The absence of this torsion may account for the position of the origin of the aorta and of the ventricle to the right, and of the pulmonary artery and its ventricle to the left, but a number of facts remain unexplained, the course of the aorta over the right bronchus, the opening of the pulmonary veins with the venae cavæ into the same cavity, &c. The author then also endeavours, setting aside the causes of the abnormal development, especially to answer the question, whether, in a case like his, we may speak of *transposition* of the arteries proceeding from the heart.

The unintelligible reasonings bearing upon this point, to be found at pages 16 and 17, lead to the conclusion that the better course is to speak of *perversion of site*. True transposition would, this appears at least to be the author's opinion, exist only if, in an otherwise normal heart, an artery should arise from the left ventricle, and ramify in the lungs, while the pulmonary artery (that is, the artery arising from the right ventricle, which would therefore receive the blood from the venae cavæ) should divide as an aorta through the body (!)

In his case the author cannot decide which is to be

called the right and which the left half of the auricle, as appears from the stated relations of the veins to the single cavity.

In the third chapter we find a description of the circulation and of the distribution of blood in the case related. The absence of a partition between the right and left auricle caused a constant admixture of arterial and venous blood after birth. Moreover, the auriculo-ventricular orifice of the aortic (in this instance the right) ventricle was very narrow, so that much more blood was driven into the pulmonary artery, which then passed again, in part, through the ductus Botalli into the aorta. The absence of the auricular septum and the narrowness of the ostium venosum of the aortic ventricle were the cause of this course of the blood, while the results (cyanosis, bronchial catarrh, cold extremities, defective nutrition) may be directly explained by the abnormal circulation.

### ON A CASE OF OSTEO-SARCOMA TELANGIECTODES; AN ACADEMIC THESIS.

By B. J. WINKELMAN, Leyden, 1865.

In a healthy workman a tumour had been developed after an injury on the inside of the humerus close to the elbow-joint. The tumour had increased in size for sixteen years after the injury, when, in consequence of a fall, fracture of the arm on a level with the tumour rendered amputation necessary.

The tumour seems to proceed from the os humeri, and communicates with the medullary cavity, while on the inside the compact substance of the bone has entirely disappeared.

The central and most solid part of the tumour consists of closely accumulated cells, and exhibits great vascularity. The surrounding tissue is looser, consists of similar cells, and is furnished with many openings. The walls of these openings present the structure of those of the capillaries—namely, a structureless transparent membrane, provided at regular intervals with nuclei. As these openings at the same time everywhere contain blood, the author thinks that they have proceeded from vessels the walls of which have coalesced. Within the tumour bony tissue is in some places met with. The whole tumour is enveloped in a fibrous capsule.

The author, on comparing this with two similar cases, one described by Lebert, the other by D. J. van Kaathoven, comes to the conclusion that this tumour has taken its origin from the spongy substance of the bone, and that its pressure has caused the compact substance to atrophy. From the extensive vascular development, which in this instance gives a peculiar character to the sarcoma, the author derives the name *osteo-sarcoma telangiectodes*.

### ON THE TEMPERATURE IN INFLAMMATION OF THE LUNG.

By S. DOEDES BREUNING.

The academic thesis of Dr. B. comprises—1st, a short "Historical Review" of our knowledge of inflammation of the lung. In this the author refers especially to the importance of thermometrical observation in pneumonia for comprehending the morbid process in its integrity, and the state of reaction in the system, as thence the typical character of the disease is recognised. The thermometrical results obtained by Wunderlich in the three typical forms of pneumonia are briefly stated. In the Second Part, "General Considerations upon the Elevated Temperature in Inflammation of the Lung," the author endeavours to show that the increased production of heat in pneumonia must be considered as the result of continued oxidation in the blood, and not of increased consumption of oxygen in the tissues. In the third chapter six cases of pneumonia are communicated from the clinique of Prof. von Geuns. The results of the thermometrical observations, obtained in these cases, quite agree with what is taught by Wunderlich. At the end of the last chapter, "Epicrisis,"

the author directs attention to the favourable influence which tartar-*emetic* seems to have exercised, in some of the cases described by him, on the diminution of the temperature. In this respect the remedy deserves a place not below but next to *digitalis*, which, on account of its disagreeable concomitant effects, is probably less to be recommended.

ON BUTTERMILK AS FOOD FOR CHILDREN UNDER ONE YEAR.  
By Dr. A. M. BALLOT. (*Ned. tijdschr. voor Geneeskunde*,  
2 afd. 4 afl.)

To find a good substitute for the mother's milk has been the object, and justly so, of many trials and investigations. Circumstances often occur, under which it is difficult or impossible to have children reared by the mother or a nurse. The most natural substitute, and that which is also most in use, is cow's milk. This is often prescribed diluted with water, the quantity of which is specified, and usually with a little bicarbonate of soda. We can indeed determine the quantity of water which is to be added, in the house where the child lives, to the milk, but we cannot then be absolutely sure of the composition which the milk so diluted will have. Even if we do not take into account the differences which may be in the milk as it comes from the cow (food, time of year, period after calving), we find a very great difference in the milk which we buy at different times from different dairymen. Analyses of different kinds of milk in Rotterdam gave the following extremes. In 1000 parts the contents amounted to

	Max.	Min.
Of Casein . . . . .	66.51 . . . . .	54.33
„ Butter . . . . .	38.00 . . . . .	21.92
„ Sugar of Milk . . . . .	34.63 . . . . .	27.5
„ Ashes . . . . .	5.50 . . . . .	2.96
„ Solid Constituents . . . . .	137.48 . . . . .	110.00
„ Water . . . . .	890.00 . . . . .	862.52

If we now compare with the mother's milk the food which the child gets, under the ordinary prescription of one part of cow's milk to two of water, we obtain for Rotterdam the following table:—

	Good Cow's Milk diluted in the proportion of 1:2.	Bad Cow's Milk.	Mother's Milk.
Casein . . . . .	24.0 . . . . .	11.0 . . . . .	34.3
Butter . . . . .	12.0 . . . . .	7.3 . . . . .	25.3
Sugar of Milk . . . . .	17.7 . . . . .	8.8 . . . . .	48.2
Ashes . . . . .	2.4 . . . . .	0.7 . . . . .	2.3
Solid Constituents . . . . .	47.0 . . . . .	37.0 . . . . .	116.4
Water . . . . .	953.0 . . . . .	963.0 . . . . .	883.6

It will be seen that this artificial food cannot be called excellent. On its use accordingly often follow vomiting of large masses of casein, diarrhoea, and atrophy. In general it is borne only by children with a strong constitution. Seeking after a more suitable substitute for mother's milk, the author found that Prof. Simon Thomas of Leyden, employed as such buttermilk with flour. Although somewhat surprised at this he determined also to make a trial of it, which gave a favourable result that was confirmed by subsequent experiments, so that this method of feeding has now, after two and a-half years, been generally adopted in Rotterdam. The analysis gave as:—

	Maximum.	Minimum.
Of lactic acid . . . . .	4.50 . . . . .	0.9
Sugar of Milk . . . . .	37.14 . . . . .	16.82
Casein . . . . .	50.95 . . . . .	36.40
Salts . . . . .	8.00 . . . . .	4.40
Butter . . . . .	4.72 . . . . .	0.21
Water . . . . .	933.84 . . . . .	906.67
Solid Matter . . . . .	93.33 . . . . .	66.66
Lactic acid after 24 hours . . . . .	5.49 . . . . .	2.06

We see the difference between them and that with mother's milk is not less than with the diluted cow's milk, and yet buttermilk seems to be better borne. How is this to be explained? Ballot thinks that the cause

lies in the lactic acid. By it the milk is already partly digested, the casein coagulated in a finely divided state, forms no large masses, which in the use of cow's milk irritate the stomach. If buttermilk be again vomited, it is in a somewhat altered state. Some persons add a little butter to the milk, to supply the want of fat. But this seems not to be necessary; the fat needful for the system appears to be formed from the carbo-hydrates. The mode of administration which Ballot adopts is this: he takes buttermilk, preferring what is not too sour (there are those who think this is a desideratum) and adds wheat flour, or if the bowels be rather free, rice flour, in the proportion of a tablespoonful to a pint and three quarters (a litre) of buttermilk; with constant stirring he brings this very thin pap to the boiling point, and allows it to boil with constant stirring for five minutes; when all is done he adds sugar to the taste. He commences the use of this very early, even in the third week. He accustoms the children gradually to the taste, giving them at first for a couple of days a few egg-spoonfuls; so soon as they get a liking for it he passes over to the bottle. The buttermilk is given lukewarm; the children almost always take to it. When this point has been attained he gives them twice a day as much as they wish, after which they must rest rather longer than after sucking. He gives it in all cases where the suck is insufficient or not good, and does not discontinue it on account of diarrhoea or other diseases, which can be treated as well under the use of this food as of suck. Lastly, in the buttermilk feeding we have this advantage, that the so much dreaded weaning fit is avoided.

Correspondence.

REMARKS ON CHOLERA IN THE EAST-END OF LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As I have had opportunities of observing the progress of cholera in the East-end of London, more especially in the Parish of Bethnal Green, it may not be out of place or presumptuous in me to state my views regarding the present epidemic, and the treatment adopted at the Winchester-street Dispensary during the time it was open. I acted as Medical Visitor, and with three assistants attended 7000 cases in six weeks, 130 being cholera, many choleraic diarrhoea, and the remainder diarrhoea; besides the above number I have seen 30 cases in private practice—making a total of 160 cases, most of which occurred in districts badly drained, and where there was a deficiency of water to meet the demands of common cleanliness; also in houses where the filth of years had been allowed to accumulate on the walls without being brushed off or whitewashed (in one or two cases the houses had not been thoroughly cleansed for over twenty years), and in some parts from friction the walls were so polished that they might well have served as a looking-glass. The district, I might more especially mention as having been the occasion for the above remarks, was Hare-street, in which street a greater number of cases occurred than in any one in my district, though some houses and streets, even worse than Hare-street, seemed for a time to escape cholera; but sooner or later they also were visited if not so severely as Hare-street.

It is not my object in mentioning the above state of the houses to try and form a theory as to the cause of cholera, and to mention the filthy habits of the people, and the want of sanitary reform in the East-end of London as being the cause of the epidemic, for were I to do so I should go nearer the west, having acted as Assistant in the West London Union for some time. I am well acquainted with both districts, so it is my intention simply to state that whether cholera depends on, or is caused by dirty houses, the filthy habits of the people, or impure water, that active measures ought to be taken by Government to remedy the evil, by appointing visitors to see that the houses in districts known to have been the dens of fever are regularly cleansed at stated periods; for, sir, thoroughly as I believe

filth to be the hand-maid of cholera, so do I believe it necessary that an official inspection of houses be made, and in saying so I do not ignore the valuable services of the Medical Officers of Health, who have done so much to stay the ravages of the disease, and I believe Dr. Sarvis, the indefatigable Officer of Health for Bethnal Green, to be worthy of all praise, for the promptitude with which he has acted during the epidemic; and not one of the least of the services rendered by him was the establishing of three dispensaries, in which over twenty-two thousand patients have been relieved, still I say there ought to be a system of inspection carried on more efficiently than at present by the Inspectors of Nuisance. The system of house-to-house visitation has doubtless done much good—in fact an incalculable amount of good—as houses which were buried in filth are now something like habitable; however, much remains to be done, but although as many as thirteen hundred houses have been visited by three assistants and myself in a week, I am impressed with the idea that, strictly speaking, much of the visiting done by medical men during the epidemic ought to have been done by the Inspectors of Nuisance, and that at a time when not excited by the presence of cholera, so as to do some little towards diminishing it altogether: but, sir, that the visiting done has been the means of diminishing the epidemic will be admitted, and the very fact of twenty-two thousand having been treated at three dispensaries in only a few weeks is sufficient proof that the vestry were right in carrying out the recommendations of their medical officer. It will also be admitted, though the Registrar-General seems to have overlooked the important fact when he attributes the sudden decline of cholera to the improvement in the water, which was found to be polluted, and, although I fully believe with him that polluted water had its share in the production of cholera, still I cannot close my eyes to the fact that the very week cholera reached its maximum, the three dispensaries were opened, at Nichol's-row, Winchester-street, and Grattan-terrace. At Winchester-street the number of applicants on the second day after it was opened numbered 587; the rush was equally great at the other dispensaries, and if it be taken into consideration that each place was regularly besieged day and night for the first fortnight after they were opened, I think it but right to conclude that the treatment of premonitory diarrhoea was certainly an important element in diminishing cholera, a fact which ought to be kept prominently in view, so that in case of another outbreak, local authorities, especially vestries, may be alive to the necessity of providing for the poor on such occasions at the very commencement.

Regarding the treatment adopted at the Winchester-street Dispensary (without condemning, as Dr. Kidd seems inclined to do, all who differ with him respecting the treatment of cholera cases, and that in a weekly paper, see *Morning Advertiser*, August 18, 1866), I have adopted all kinds of treatment—both the astringent and eliminative—and have found patients derive benefit from both modes, but am fully convinced that I have seen more benefit derived from the administration of chlorate of potash, in the form of powder, than from any single drug, and in some cases the effect has certainly been remarkable, oftentimes relieving sickness and bringing about reaction in extreme cases of collapse; still I would not have any one believe that chlorate of potash was infallible more than castor-oil, or any astringent, but what I say is (and there are other medical practitioners who can say the same) that chlorate of potash, combined with a judicious administration of astringents where the dejections are frequent has given better results, and a large per centage of recoveries (I am below the mark when I say seventy-five per cent.), than either plan of treatment alone.

The *modus operandi* of the drug I don't pretend to explain, as there are conflicting views respecting its operation; but surely, sir, we are not to weed the Pharmacopœia of drugs known to be of great benefit in cases of scarlatina, cancrum oris, &c., because its *modus operandi* can't be chemically explained, although from the sudden change of the countenance and fingers, from being blue or livid, to their natural colour, I am inclined to think that, chemically, it does act, as generally supposed, by oxidizing the blood; but if we ignore such a statement from the fact that it is not supposed to be absorbed, then I believe it probable (taking into account the large amount of chlorine introduced when given in the form of powder)—a form I always insist upon—that besides introducing into the system, and making up for what is known to be thrown off largely in the excretions of

cholera patients (chlorides), that some chemical change takes place, or its action upon the periphery of the nerves of the stomach and intestines is such that by reflex action the beneficial effects described are brought about, and one which I ought to have mentioned is the large quantity of urine voided.

I have been led to give the chlorate of potash in powder in cases of cholera from having observed its different effects, in the form of solution and powder, in cases of ulceration of the tongue. Some time since I had two or three very bad cases of ulceration of the tongue and pharynx under treatment, and had tried a solution of the chlorate of potash without the least improvement in the appearance of the ulcers, although containing the solution of chlorate of potash, for six weeks. At this time one of your correspondents mentioned the circumstance of his having had under treatment a similar case, which did not improve while using a solution of the drug, but rapidly got well by sprinkling the ulcers over with the powder two or three times in a day, so I at once tried the powder, as mentioned in the cases under treatment, and was pleased to find the ulcers get rapidly well.

I am aware that chlorate of potash has been given in cholera cases, in solution, but am not aware that the powder has been given, and that given in solution it is but little thought of; but, setting aside the fact that the powder mixed up in a little jelly is much more readily retained on an irritable stomach than the same quantity in solution, I imagine it quite possible, and even probable, that the powder, being the most concentrated form, may act by chemically decomposing the intestinal secretions, or, as I said before, by acting on the sympathetic system of nerves, and so altering the character of the secretions; and if so, the different effects of the drug may be as great in cases of cholera as in cases of ulceration of the tongue; so I can readily understand the fact of its failure as hitherto used in the form of solution, and think it deserves further trial before being condemned.

The mixture generally used at the dispensary was tr. opii minimi v-10; T. capsici gtt. i; T. catechu 5ss; æther chloric minimi x to xv; with mist. creta to an ounce; and that seemed to check the diarrhoea in the majority of cases; but if the disease ran on to the second stage, I generally used to alternate the mixture with powders of chlorate of potash, or gave the potash alone without the mixture if the diarrhoea had ceased or was abating.

In cases where the patient complained of pain in the bowels, a feeling of constriction as if tied around the waist with a cord, sickness, and cramps, but no diarrhoea, then tr. of opium and castor-oil acted well; but as I have not used castor-oil sufficiently extensive to justify my expressing a decided opinion as to its effects, all I can say is that as opium was only given in sufficient quantity to relieve pain. I attribute the beneficial effects, and especially the relief afforded when the bowels were relieved, to the eliminative effects of the oil.

But, sir, strongly as I have spoken of chlorate of potash, and convinced as I am that much good has been done by its administration, I believe the time has not yet arrived to place reliance upon any one drug, but feel confident that we may at no distant period find cholera to be as amenable to treatment as pneumonia, or fever—to which it is more nearly allied—is in the present day.

C. C. RICHARDS, M.D.

Brick-lane, Bethnal-green, December, 1866.

#### MEDICAL INSPECTORS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question I took the liberty of asking a year ago still presses itself on the notice of an observer—What has become of the Medical Inspectors? We hear a good deal about their appointment, &c., through your columns, and from other sources, but so far as seeing them, or any service to some parts of the country from their existence, is concerned, they might be as well among the myths of bygone ages. I am not inclined to place a very high value on the services of those gentlemen. Nevertheless, they did constitute a kind of arbitership, to which an honourable-minded medical officer might have recourse from time to time in the discharge of his duty to the poor, and in the assertion of his own just rights and privileges, without the somewhat obnoxious course of writing to the Commissioners, which is the

only one now left to him. It is true that to those medical officers who fall in with the views of the ratepayers in keeping down the rates to the lowest possible figure, things go on very smoothly—albeit the poor are neglected and stinted in the necessaries of both food and medicine which the law contemplates supplying them with, and are sometimes left to the care of (it may be incompetent or careless) subordinates; while the man who draws the salary which the law appropriates for their attendance, is engaged among the rich, or with his farm, or merchandize. But, sir, there are some medical officers, I take pride in believing there are many, who having engaged for a certain salary to give medical attendance to the poor of a district, and as far as in him lies, to avert therefrom pestilential diseases, applies himself in earnest to that as his chief duty, in the discharge of which he sometimes incurs both opposition and odium, because haply he considers the lives and health of the poor and labouring class of more importance than a few shillings more or less on the rates.

This, you will agree, is rather a lamentable state of things. The Registration Law, however perfect in the lapse of years it may become, as yet forms a very inadequate test of the sanitary condition of the country, and its returns seem calculated to mislead the public, and perhaps to lull the Commissioners into too great a security as to the working of the poor-law machinery. The administration of the relief to the sick poor is left much as it was in former times—*i. e.*, between the local governing bodies (boards and committees) on the one side, and the medical officers on the other; but with this difference and disadvantage, that whereas under the old system the contributions were voluntary, and there was consequently no antagonism between the contributors and the doctors, who were thus placed in a position more favourable for the good of the country. Under the present system the contributors—*i. e.*, the ratepayers—are under compulsion to support the doctor, who is therefore liable to be regarded as a Government officer forced on and supported by the people, and therefore to be made the most of at the least possible expense either of money or courtesy. As might be expected, the Doctor is too often fain to purchase favour and a quiet life by falling in with the views of cheeseparing guardians—a line of conduct more politic than humane and just to the poor.

The Medical Inspectors *might* constitute a barrier against this degenerating tendency in the working of the poor-law. But they are nearly unknown, not having been seen or heard of, in some districts for more than *five years*.—I remain, sir, your obedient servant,

DISPENSARIUS.

### "TELEGRAPHING FOR THE DOCTOR."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—No doubt every physician in the habit of receiving telegrams can testify to the truth of the statements made by a writer in your journal of December 19th. As at present managed, the telegraphic service of the country is in a most unsatisfactory state. Last night furnished me with an additional proof of this. A telegram requesting my immediate attendance for a consultation was forwarded, or supposed to have been forwarded, at half-past ten P.M., from a distance of about six miles from Charing-cross. The message was delivered at my house a few minutes before two A.M. It is needless to detail the inconvenience and annoyance caused by such culpable negligence, and it is to be hoped that some system will be devised to obviate the possibility of such occurrences.—I am, sir, &c.,

A. L.

### DISEASES OF THE EAR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I would suggest to your correspondent "Miser" the advisability of submitting, together with his question of December 19th, a statement of the physical examination of his ear. The *symptoms* he alludes to may be due to very serious causes—mechanical or vital—and therefore no one line of treatment can be recommended with confidence as long as the condition of the external auditory passage, the membrana tympani, the cavitas tympani, ossicula, Eustachian tube, &c., is unknown.—I am, sir, yours obediently,

SPECULUM.

## LEGAL INTELLIGENCE.

### CHARGE OF ILLEGALLY RECEIVING A LUNATIC PATIENT.

AT Bow-street a summons was preferred at the instance of the Commissioners in Lunacy against Mr. George Naylor, Surgeon, of 8, George-street, Hanover-square, charging him with having taken the charge and care of a person of unsound mind, without the proper order or medical certificate. The prosecution was conducted by Mr. Metcalfe, instructed by Messrs. Vandercombe, Law, and Co., solicitors to the Board of Commissioners in Lunacy; and Mr. Harrison, instructed by Messrs. Lewin and Co., defended. Mr. Metcalfe, in opening the case, said the proceedings were taken under the sections 90 and 91 of the Act 8th and 9th of Victoria, cap. 100. It appeared that in October last a young man, whose name he did not mention, being unwilling to make a family affliction unnecessarily public, was sent as a lunatic patient to Southall-park Asylum, with a certificate signed by the defendant. It appeared from it that the defendant had examined him at Deane's cottage, Hanwell, and had come to the conclusion that he was of unsound mind. It was not, however, stated that the defendant, who described himself as a Surgeon practising at 8, George-street, Hanover-square, was also residing at Deane's cottage, Hanwell, and was the person in whose care and charge the patient had been for the preceding seven and a half months. The evidence would show that this was so, Mr. Naylor having signed an agreement by which he undertook the charge, board, and lodging of the patient, providing him with wine, &c., in fact everything but clothing, for £2 10s. per week. At that time the patient had been for twelve years in a state of imbecility, brought on by over-study. In the opinion of Dr. Allen, who had examined him prior to his removal from his father's house to Deane's-cottage, he was incurable. During the early part of his stay at Deane's-cottage he appeared to improve, but in October, as he seemed to be getting worse again, he was removed by his father's suggestion to the asylum. Mr. Harrison cross-examined the witnesses, endeavouring to show that defendant was not aware that the patient's mind was affected until lately, and also that the prisoner was not under his charge (notwithstanding the agreement), but, under that of a widow lady residing at Deane's-cottage. Counsel also suggested that he had witnesses to call, but, on Mr. Vaughan's intimation that unless their evidence was most stringent the case must go for trial, Mr. Harrison reserved the defence, observing, however, that if Mr. Naylor had committed any infringement of the Act it was rather an error of judgment than a wilful offence. The defendant was committed for trial, bail being taken in two sureties of £100 and himself in £200.

## Medical News.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of Candidates who passed the Major Examination, December 19, 1866, as Pharmaceutical Chemists:—

Churchyard, Robert Leman, Bungay. ■  
Moussempes, Jules, Biarritz.  
Allkins, Thomas Boulton, Tamworth.  
Cornelius, Richard Bayly, Clapham.  
Ford, Edward Beeks, Hereford.  
Johnson, Edwin Eli, Nottingham.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows, held on Saturday, December 22, the following Member of the College was duly admitted a Fellow of the same:—

Nathaniel Allan Travis, Nice.

At the same meeting the following gentlemen, having undergone the necessary Examination, were duly admitted Members of the College:—

Thomas Tillyer Whipham, M.B.Oxon., St. George's Hospital; Christian Gottfried Heinrich Bäumlér, M.D.Erlangen, 10, Finsbury-place, North; Walter Balls Headley, M.B.Cantab., 5, Tavistock-place; Francis Valentine Paxton, M.B.Oxon., West Dean, Chichester; Frederic Bateman, M.D.Aberdeen, Norwich; Robert James Lee, M.B.Cantab., 4, Savile-row.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of

Medicine, and received certificates to practice, on Thursday, December, 20, 1866:—

Thomas Alpheus Buck (Guy's Hospital), Kennington-park road; John Jenkins (Guy's Hospital), Castleton, near Cowbridge; James Brierley Hughes (St. Bartholomew's Hospital), The Rectory, Congleton; William Frederick Knapp (St. Bartholomew's Hospital), St. Bartholomew's Hospital; George Fred. Sankey (St. Thomas's Hospital), Ashford, Kent; Augustus Constable Maybury (St. Thomas's Hospital), Frimley, Surrey; William Powell (Charing-cross Hospital), Shirley, Southampton; Edward James Pollock (King's College Hospital), Holford Hounslow, W.; Joseph Oakman (Westminster Hospital), Hillside, Wimbledon; William Askwith Rudd (Hull Medical School), Hull; Reginald Ratcliff Hoare (Birmingham General Hospital), Mount-street, Birmingham.

The following gentlemen also on the same day passed their First Examination:—

George Mason, Guy's Hospital; John Carr, Guy's Hospital; Robert Longust Sheffield, London Hospital.

#### MANFIELD'S PROCESS FOR PRESERVING VEGETABLES.—

In this process, which has been lately patented by Messrs. Burgess and Sons, 107, Strand, London, the pickling of vegetables is effected by means of an apparatus which, after exhausting the articles of the water they contain, forces in the vinegar by atmospheric pressure, and the object of the manufacturer is thus accomplished in a very short time, instead of its occupying several weeks, as heretofore. The vessel in which the vacuum is formed is lined with platinum in order that no metallic impregnation may enter the pickles, and the apparatus is worked by a powerful steam engine.

#### THE NEW VAGRANT WARDS FOR THE HOLBORN UNION.—

This building, which is, we believe, the first of its class erected in London, is now completed and occupied. It is situated in Vine-street, Liquorpond-street, the ground on which it stands having been cleared of buildings for the purpose. Externally it presents the appearance of four ordinary dwelling-houses, the architect being instructed so to plan the structure that in the event of its not being required for the uses to which it is now appropriated it could be readily converted into dwelling-houses, with a range of workshops in the rear. The plan of the interior may be thus described:—There is an entrance-hall, on admission to which the division of the sexes is at once effected, the females passing to the right, the males to the left. Immediately in connection with the receiving wards are the baths, water-closets, and urinals, as also store-rooms, in which the clothes of the inmates are locked up during the night, care being taken first to pass them through the vermin exterminator which has been provided. The sleeping wards, containing ninety-six beds, are in the rear on the ground and one-pair storey, the whole being both lighted and ventilated from the roof, large well-holes having been formed in the floor of the one-pair storey for the purpose. The ventilation, is effected by means of a number of hooded cowls fixed in the roof with rings of gas placed below them to produce an upward current, the fresh air being introduced at the level of the floors. As the building will only be occupied at night, the plan of ventilation adopted would seem to be specially designed to meet that circumstance, depending upon the use of the gas rings in the roof for complete development. No doubt the fact of the front wall being the only one of the external boundaries available for lighting and ventilating the building had considerable weight in determining the use of the roof for these purposes. Be that as it may, the difficulties of the site in this respect seem to have been effectually overcome by the means we have described. Complete supervision over the inmates is obtained by the attendants' room being glazed on all sides, and their being so located as to command a full view of the wards. The labour test would seem to consist of oakum-picking for the females, and stone-breaking for the males, accommodation for both being furnished. Open fireplaces have been provided in all the wards, but this apparently has been done to meet any further requirements arising out of the conversion of the building, since the whole is now heated by means of hot water. A residence for the superintendent and his wife has been erected immediately adjoining the male wards, with a private staircase and entrance from the street. The contract price for the whole was £2662.—*City Press.*

**HOW TO LIGHT A DARK ROOM.**—If, in a very narrow street or lane, we look out of a window with the eye in the same plane as the outer face of the wall in which the window is placed, we shall see the whole of the sky by

which the apartment can be illuminated. If we now withdraw the eye inwards we shall gradually lose sight of the sky till it wholly disappears, which may take place when the eye is only six or eight inches from its first position. In such a case the apartment is illuminated only by the light reflected from the opposite wall or the sides of the stones which form the window; because, if the glass of the window is six or eight inches within the wall, as it generally is, not a ray of light can fall upon it. If we now remove our window and substitute another in which all the panes of glass are roughly ground on the outside, and flush with the outer wall, the light from the whole of the visible sky, and from the remotest parts of the opposite wall, will be introduced into the apartment, reflected from the innumerable faces or facets which the rough grinding of the glass had produced. The whole window will appear as if the sky were beyond it, and from every point of this luminous surface light will radiate into all parts of the room.—*Builder.*

**CHOLERA AND QUARANTINE AT MALTA.**—The officer administering the government of the island of Malta having received official information that cholera has ceased at Constantinople, Smyrna, and Alexandria, and having heard the opinion of the Board of Health, was, under date of Dec. 17, pleased to direct that arrivals from those ports be admitted to pratique; and that vessels arriving from Naples, furnished with clean bills of health, be also admitted to pratique. By another notice, dated the 18th, he further directs that arrivals from the Sea of Azof, the Black Sea, and the Sea of Marmora, be likewise admitted to pratique; and that vessels arriving from Turkish Albania, Taranto, and its vicinity, be subjected to a quarantine of 15 full days from the date of their arrival.

**EARLY STRUGGLES OF MEDICAL MEN.**—Dr. John Cheyne, who, a quarter of a century ago, was by far the busiest and best employed physician in Dublin, tells us, in his interesting autobiography, that, during the first half of his second year's settlement in the Irish capital, and when he had already reached the thirty-fourth year of his age, his fees only amounted to about three guineas. Nine years subsequently, he was making £5000 annually. Not above one or two physicians in London ever drew, I believe, a larger professional income, or, perhaps, ever advanced more early into full practice, than Dr. Chambers; yet, during the fifth year of his practice, when he was already thirty-four or thirty-five years of age, he did not receive above £211 in fees. Seventeen years subsequently, his annual professional income is stated to have reached nearly to £9000. His great predecessor in high London practice, Dr. Matthew Baillie, drew above £11,000 in one year; and yet, with all the interest of the Hunters and others to aid him in his outset, his first march upwards was, like that of all others, very slow and difficult, and, to quote the words of his biographer, Dr. Wardrop, before "he found himself fairly established in practice," he had been ready for twelve years physician to St. George's Hospital, and for nearly twenty years a medical lecturer. Dr. Baillie's uncle, the celebrated Dr. William Hunter, who spent a large fortune, gained by his profession alone, upon the collection of that splendid museum which now enriches the University of Glasgow, was so hard pressed for money, during the years of his earlier struggles in London practice, that he was obliged to postpone for a fortnight the commencement of his third season of lectures, in consequence of not having money enough to pay the expense of the usual class advertisements. Nor have our greatest surgeons been usually more successful than these our greatest physicians, in the first stages of their professional career. In 1788 the son of an English clergyman attended the medical classes of Edinburgh University, and lived on the third flat in Bristo-street, in a room which cost him six shillings and sixpence a week. In after life, when swaying the surgical sceptre of England, as Sir Astley Cooper, his professional income, in one single year, amounted to £23,000; and yet, during the first twelve months after he settled down in London, and was working as a lecturer on anatomy and surgery, his receipts from private practice only amounted to five guineas. The distinguished surgeon who, by Sir Astley's death, was left at the head of the surgical school of London, Sir Benjamin Brodie, did not, as we are told, in a late biographical sketch of him, get into "full practice" till 1825; yet he had been lecturing, practising, and publishing since 1805, or for twenty long years previously.—*Leisure Hour.*

**THE LONDON CASUAL WARDS.**—The active measures which the Poor-law Board took last winter to compel the London Guardians to carry out the Houseless Poor Act have to some extent operated well for this winter, but some facts have come to light showing that the letter as well as the spirit of this benevolent measure of the Legislature, which was passed in order that there should be no excuse for persons wandering about the metropolis without a home, is being wilfully and cruelly contravened. It will be remembered that the Clerkenwell Guardians would not for a long time place themselves under the Act, and provide decent wards for the homeless. By this neglect many additional burdens were thrown upon this heavily-taxed parish, as all the expenses of relieving the casual poor came upon the parish rates, instead of being paid for out of the metropolis rates. This winter, properly-certified wards have been provided in Clerkenwell-close, and the manner in which the law is being administered is best shown in the relation of an occurrence which took place between Saturday night and Sunday morning last, and which will be brought under the notice of the authorities. At a little after midnight on Saturday night, during the fall of a drenching misty rain, two miserable men were seen crouching about the door of the wards. They were interrogated by a passer-by, and they said they had got into town in the evening, and had been directed from place to place until they stood where they did. The onlooker knocked at the door of the wards, and the administrator of the Poor-law answered the knock, and when warned that it was his duty not to turn away applicants for shelter, he would not say why he refused them admission, and, after charging the stranger with the heinous offence of having brought casuals there on a previous evening, he threatened to give him into custody for knocking at the door. One of the casuals appealed to the keeper of the wards to give him a night's lodging. "I have served my country for eleven years," he said, "and it is hard that I cannot get a night's lodging on a night like this." "Then you should look to your country to do something for you" was the rejoinder, and a policeman who came up just before expressed the view that the wanderers should have come before that time. To this the broken-down soldier replied that he and his mate arrived late in the evening, and had last been sent from a place which, from his description, must be the West London Union wards, and had waited for hours before refusal. They could get no lodgings at the Clerkenwell wards, which are placed by the Homeless Poor Act under the express rule that every applicant is to be dealt with in some manner—relieved if necessitous, given into custody if criminal, or handed over to the care of the relieving officer if a parishioner; and the two men wandered forth to seek at the hands of the benevolent, or in some desperate act, the means of existence vouchsafed to them by the Legislature, and thus withheld by the administrators of the Poor-law.—*Times*.

## Appointments.

**BARBOUR, Dr. J.,** L.R.C.S. Ed., has been appointed Resident Medical Officer to the London Fever Hospital.  
**CULLINGWORTH, CHARLES JAMES,** M.R.C.S. Eng., etc., has been appointed Physician's Assistant at the Manchester Royal Infirmary.  
**ELLIS, T.S.,** M.R.C.S.E., has been appointed Assistant-Surgeon to the Hospital for Sick Children, Gloucester.  
**KELLY, C.,** M.B., has been appointed Resident Medical Officer to the Public Dispensary, Carey-street, Lincoln's Inn.  
**NASH, W. L.,** M.R.C.S.E., has been appointed Resident Surgeon and Apothecary to the Buckinghamshire General Infirmary, Aylesbury.  
**TEEVAN, Mr.,** F.R.C.S., B.A., has been appointed Lecturer on Anatomy at the Westminster Hospital, vice Mr. Heath, resigned.

## VACANCIES.

Chorlton-on-Medlock and Rusholme Dispensary.—Surgeon.  
 Cumberland and Westmoreland County Lunatic Asylum.—Assistant Medical Officer.

## RESIGNATIONS.

Cuckfield Union.—Fifth district; area 7484; population 2758; salary £50 per annum.  
 Darlington Union.—Barton district; area 12,935; population 2185; salary £28 per annum.  
 Nuneaton Union.—Nuneaton district; area 7520; population 7845; salary £55 per annum.  
 Selby Union.—Townships of North and Skipwith; area 5058; population 769; salary £5 10s. per annum.

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

Every MS. should bear the Name and Address of the Sender.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be *legibly* written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

*Dr. Chambers.*—Received with thanks. Will be attended to.

*Dr. Griffiths.*—Postponed.

*T. K.*—The article reached us too late.

*Obstetrician.*—Our information was obtained from several distinct and trustworthy sources.

*Dr. Clark.*—The copies were duly sent.

*C. F.*—A private note.

*Double Facial Palsy.*—I observe a case of this kind, treated by Dr. Lyons, reported in THE MEDICAL PRESS AND CIRCULAR, Dec. 19, 1886. The reporter remarks that "of the rarity of the affection in its double seizure some opinion may be formed from the fact that no mention is made of it in the works of Walton, Trousseau, or Aitken." Mackewh (Practical Treatise on Diseases of the Eyes, 4th edition, p. 184), remarks that "in some cases both sides of the face are palsied;" and refers to Magnus, Müller's Archiv for 1837, p. 258. He adds—"A case of this kind, which I saw, arose from a poor man being maltreated on the road, and kicked on the occiput." BASIL.

*Sr.*—Will you kindly afford space to inquire of any of your readers who, as Union Medical Officer, has held the post of "Medical Visitor" in the provinces during the recent epidemic, what the scale of remuneration from the Guardians has been?—Yours faithfully,

SOUTH DEVON.

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

**BLANDFORD.**—On December 18, at 3, Clarges-street, W., the wife of G. F. Blandford, M.B. Oxon, of a son.  
**BRENCHLEY.**—On December 19, at Denmark-hill, Camberwell, the wife of H. C. Brenchley, M.R.C.S.E., of a daughter.  
**DE CHAUMONT.**—On December 16, at Oakland, Woolston, Hants, the wife of F. De Chaumont, M.D., Staff Surgeon, of a daughter.  
**JONES.**—On December 24, at 174, Blackfriars-road, the wife of F. C. Jones, M.D., of a son.  
**ROSE.**—On December 11, at San Remo, Italy, the wife of Dr. F. Rose, of a son.  
**SALMON.**—On December 14, at No. 3, Kempt-terrace, Woolwich-common, the wife of J. Salmon, M.D., Deputy-Inspector-General of the Royal Marine Infirmary, Woolwich, of a daughter.

### MARRIAGES.

**BOOTH—HUNT.**—On December 18, at St. Lawrence's Church, Measham, Derbyshire, J. Webb Booth, M.R.C.S.E., L.S.A., to Isabella, third daughter of the late G. Hunt, Esq., Measham.  
**DAVIS—NIXON.**—On the 25th September, by the Rev. J. A. Welsh Collins, B.A., Chaplain to the Forces at Sedgebrook Grange, Waunganui, New Zealand, the residence of the bride's father, James Davis, Esq., L.R.C.S.I., Assistant-Surgeon H. M. 57th Regiment, to Clara Agnes Elizabeth, third daughter of John Nixon, Esq.  
**FLEMING—MATHERS.**—On December 20, at Partick, near Glasgow, J. M. Fleming, M.D., her Majesty's Indian Army, to Catherine Rennie, eldest daughter of A. Mathers, Esq., Secretary Clydesdale Bank, Glasgow.  
**MILLER—PHIPPS.**—On December 10, at Galle Face Church, Colombo, Ceylon, Staff Surgeon C. M. Miller to Mary A., daughter of the late Mr. E. Phipps, of London.  
**STANLEY—ROBINSON.**—On November 3, at Trinity Church, Kurachee, Scinde, East Indies, by the Rev. H. W. Bagnell, M.A., St. John Stanley, Staff-Surgeon Army, to Emily, youngest daughter of the late Rev. C. W. Robinson, M.A., formerly of Leominster, Herefordshire.

### DEATHS.

**DANDY.**—On December 21, at Rufford, near Ormskirk, C. Dandy, M.R.C.S.E., aged 74.  
**HASLEWOOD.**—On December 9, W. Haslewood, M.D. Edin., of Darlington, Durham, aged 64.  
**JACKSON.**—On December 14, at 44, Upper Brook-street, Manchester, R. Jackson, M.R.C.S.E., aged 43.  
**NOEL.**—On December 6, V. E. Noel, M.R.C.S.E., of Westbury-terrace, Plymouth.  
**TAIT.**—On December 20, at Enfield-highway, R. Tait, Surgeon, aged 71.

Original Communications.

CASES OF SOFTENING OF THE BRAIN.

By JOHN W. OGLE, M.D.,

PHYSICIAN TO, AND LECTURER ON MEDICAL PATHOLOGY AT, ST. GEORGE'S HOSPITAL, ETC.

(Continued from page 637, vol. ii., 1866.)

SOFTENING OF THE SURFACE OF THE RIGHT HEMISPHERE OF THE BRAIN; SLOUGHING OF THE DURA-MATER, FOLLOWING A SCALP WOUND; TETANUS-LIKE SYMPTOMS ON THE LEFT SIDE OF THE BODY

Case 112.—George C., aged 29, an intemperate man, was admitted March 17th, 1859, having sustained a fracture of the clavicle and a scalp wound in front of the right ear, the bone, however, not being exposed. Since the accident he had lost the sense of hearing in the right ear. Fever came on, followed by delirium, for which salines and opium were given. Eight days afterwards violent delirium came on during the night, and twitchings of the left side of the face. The tongue was dry and brown. Much puffiness of the scalp existed, and purulent fluid was evacuated. Pain came on in the left hand, also the left side of the body, and the left thigh, and there was a spasmodic condition of the left side of the body, resembling tetanus. Abscesses formed in the thumb, and on the wrist, which were opened, and a fullness of both lips was observed. On the 31st he became more delirious, but answers were rationally given, and there was no headache. Abscesses formed about the injured clavicle. Delirium continued, and he died April 3rd.

*Post-mortem Examination.*—The membrana tympani was found to contain an opening, but the tympanum was uninjured, as were also the cranial bones; but, corresponding to the scalp wound and the centre of the right cerebral hemisphere, a small patch of the dura-mater was in a sloughing condition. The surface of the convolutions of the brain at this part was softened to about the size of a sixpenny piece in area, and to a slight depth in extent. At this spot the membranes were agglutinated. In other respects the brain was healthy. *Thorax.*—Several ribs, in addition to the clavicle, were found to be fractured, and a quantity of pus in connection was only kept out of the pleural cavity by the pleuræ. Abscesses were found connected with either hip-joint. (68.)

SOFTENING OF THE CENTRAL WHITE PARTS OF THE BRAIN; DISEASE OF THE KIDNEYS, AND EMPYEMA, FOLLOWING SCARLET FEVER.

Case 113.—John B., aged 4, was admitted April 15, 1859, for a slight burn. Whilst in the hospital he contracted scarlet fever, and went on well, until dropsy came on, and albuminuria, with effusion of fluid into the chest. Drowsiness came on, and the dropsy quite disappeared. Convulsions supervened before death, which occurred August 7th.

*Post-mortem Examination.—Thorax and Abdomen.*—The kidneys were very much diseased, and much fluid, with pus, was found in the pleural cavities. *Cranium.*—Much, rather turbid, fluid existed in the ventricles, and beneath the arachnoid membrane. The fornix and septum-lucidum were so softened as to be in a shreddy, broken-down condition. (184.)

SOFTENING OF THE FORNIX; DISTENSION OF THE CEREBRAL VENTRICLES; DELIRIUM, FOLLOWED BY HEMIPLEGIA ON THE LEFT SIDE.

Case 114.—George R. was admitted December 10th, 1859. He had enjoyed excellent health, but for a week had had a slight cough. In the middle of the night before he came to the hospital he was found talking

nonsense, and insisting on walking down stairs, and when admitted he was quite absorbed in himself, heedless of surrounding objects, but not wholly unconscious. The left cheek was flapping, and there was incomplete paralysis of the left arm and leg, the skin of the left side being cold, and he was often fumbling the bedclothes with the left hand. The pupils were natural. There was decided dysphagia. On the 11th the evacuations were passed unconsciously. Stertor and a fixed and contracted state of the pupils came on, the left one seeming rather the larger, and he died on the 15th.

*Post-mortem Examination.—Cranium.*—The bones of the skull were very thick. The brain-substance was firm and natural in all parts except the fornix, which was so softened as to be almost diffuent. The lateral ventricles were large and distended, but equally so, with fluid. The arteries at the base of the brain were atheromatous. The other organs of the body were not examined. (269.)

SOFTENING OF THE SURFACE OF THE LEFT CEREBRAL HEMISPHERE, FOLLOWING INJURY TO THE HEAD; HEMIPLEGIA ON THE RIGHT SIDE.

Case 115.—William B., aged 52, was admitted August 29th, 1862. He had been very intemperate, and two months previously had been struck on the head with an iron gate, being rendered insensible by the blow. A superficial wound had been caused that healed quickly. He recovered at the time, and went on well until a week before admission, when he suddenly fell down in the street insensible. Being seen by some medical man, leeches to the head and purgatives were resorted to, but he was admitted to the hospital in a state of unconsciousness, with absolute loss of power, and diminished sensibility of the skin of the right half of the body. The right eye was more open than its fellow, and its pupil was more dilated than that of the other eye; there was, also, occasional strabismus, and the breathing was stertorous. The temperature of the surface of the body was the same on both sides. There was much dysphagia, and the evacuations were passed involuntarily. The sounds at the base of the heart were rough, but free from bruit; the urine was albuminous. He was treated with purgatives, and cold applications to the head. Noisiness and great restlessness came on, and afterwards bed-sores. Later on he had somewhat more of consciousness; but the pulse subsequently became quick and irregular; he became suddenly attacked with severe dyspnoea, followed by coma; and in spite of stimulants, counter-irritants, &c., collapse came on, and he died September 7th.

*Post-mortem Examination.—Thorax.*—The aorta was atheromatous, otherwise the organs were natural. *Abdomen.*—One of the kidneys was found to contain calculi, as also one ureter. *Cranium.*—A scar existed on the scalp, on the left side of the head, and corresponding to this part, on opening the cranium, the dura-mater was found to be adherent to the skull. The arachnoid membrane, generally, was thickened, and in parts opaque; much fluid existed beneath the membrane, especially on the left side, where the cerebral convolutions (both white and grey matter) were softened, the grey matter near the surface being of a very yellow colour. The posterior part of the middle lobe was mainly affected, and here was observable a small spot of bloody ecchymosis. The other parts of the brain were natural. (242.)

SOFTENING OF THE FORNIX AND SEPTUM-LUCIDUM; DELIRIUM TREMENS; SUDDEN DEATH.

Case 116.—George B., aged 30, was admitted October 6th, 1862, in a state of delirium tremens, having had no sleep for two days. He was sweating much; his pulse was 82, and very weak. Opium and ammonia were given. The next day he was incoherent, and had to be confined down in bed. Tartar-emetac was given every hour. In an attempt to struggle and free himself from restraint he fell down dead.

*Post-mortem Examination.—Thorax and Abdomen.*—The liver was in a fatty state, and the capsules of the kidneys

rather adherent. The other organs natural. *Cranium*.—The cerebral veins were distended; the brain, generally, was "wet," and much serum existed in the ventricles. The fornix and septum-lucidum were decidedly softened. (277.)

EXTENSIVE SOFTENING OF THE BRAIN; COMA BEFORE DEATH.

*Case 117.*—John P., aged 45, a very intemperate man, had nevertheless enjoyed good general health, until a week before admission into the Leeds "House of Recovery" (Fever Hospital), August 10th, 1862, when he was noticed as becoming altered in his behaviour, staring about, and being very absent in manner. On the day before admission he came down stairs dressed with two large scarfs about his head, but was persuaded to remain indoors, and sat down, apparently unconscious. On admission he was very stupid, and it was impossible to get a sensible answer from him. There was no history of insanity in his family. A blister was applied to his neck, and cold applications to the head, and he was well purged. He was more conscious the following day, but soon relapsed into complete insensibility, and the urine had to be drawn off with the catheter. He died the eighth day after admission.

*Post-mortem Examination—Cranium.*—The cranial bones and cerebral membranes were natural. The blood-vessels of the brain were very much congested throughout its entire substance. Both cerebral hemispheres were extensively softened throughout their entire substance, and the fornix and septum of the ventricles were quite diffuent. The corpora-striata and thalami-optici, though highly congested and diminished in consistency, were not at all easily broken down. The cerebellum and pons Varolii were healthy.\*

SOFTENING OF THE SUPERFICIAL CEREBRAL CONVOLUTIONS, WITH YELLOW DISCOLORISATION; SYMPTOMS OF FEVER, FOLLOWED BY PNEUMONIA.

*Case 118.*—Robert H., aged 35, was admitted January 14th, 1863, with well-marked symptoms of typhus fever. There was great contraction of the pupils, and extreme stupor came on, with involuntary passage of the stools. For a time he became so far rational as to answer questions, but relapsed into noisy delirium. After a time, he recovered his mental condition, but pneumonia and pleurisy set in, and he died January 29th.

*Post-mortem Examination—Thorax and Abdomen.*—Abscesses of the lung and pleural adhesions were found, and the spleen was in a very pulpy state. *Cranium.*—The dura-mater, generally, was adherent to the bone. On the surface of the cerebral convolutions of both hemispheres small patches of yellow discolorisation (as of blood extravasations of old standing) existed. The brain immediately below these parts was somewhat, but decidedly, softened to the depth of about one-eighth of an inch. (25.)

SOFTENING OF THE LEFT CEREBRAL HEMISPHERE BELOW THE CORPUS-STRIATUM; PLUGGING-UP OF MANY INTRA-CRANIAL ARTERIES; PERFORATION OF A MITRAL VALVE-FLAP.

*Case 119.*—Margaret Reid, aged 43, was admitted November 29th, 1863, in an "apoplectic fit." She had never had one before, and the present attack was preceded by giddiness, though not of long standing. The limbs on the left side of the body were quite paralyzed, and the right leg was frequently drawn up, whilst the right hand was constantly being raised up to rub the face. A little beef-tea was swallowed with difficulty. She sank within a few hours of admission; no return of consciousness having taken place.

*Post-mortem Examination.*—The aortic and mitral valves of the heart were much diseased, and the latter much destroyed by fibroid deposit, contained a round buttonhole-like opening. No recently formed fibrine could be found on any of the valves or surfaces of the cavities of the heart. A few old pleural adhesions existed. *Abdomen.*—One of the kidneys contained several calculi. *Cranium.*—Dura-mater firmly adherent to the skull. The veins on the sur-

face of the brain were very distended, and the white cerebral matter was very vascular. Immediately under the surface of the left corpus-striatum was a small circumscribed portion of brain tissue, which, retaining its colour, had quite lost its firmness, and was in a porous and spongy condition. This condition existed to an extent of about the size of a hazel nut.

*Microscopical Examination.*—The softened part was shown to contain much coarse granular matter, with some opaque granular cylinders, which might have been obstructed blood-vessels.

Many of the arteries at the base of the brain were obstructed by fibrinous coagula, chiefly on the right side. The termination of the right internal carotid was obstructed by a plug, one and a-half inch long, slightly adherent to the artery, and many others were found, as in the posterior cerebral artery on the left side, generally about an inch long. Both the cerebral hemispheres were, however, of the natural consistency. (288.)

SUPPOSED SOFTENING OF THE BRAIN; HEMIPLEGIA (PARTIAL) ON THE RIGHT SIDE OF THE BODY, WITH FACIAL PARALYSIS ON THE LEFT SIDE.

*Case 120.*—Thomas C., aged 42, a wheel-wright, having been previously in good health, was, about a year before he was admitted into the hospital, affected with giddiness, pain in the forehead, and a certain degree of loss of power on the right side. About six weeks before admission he for the first time found great difficulty in articulating distinctly, and occasionally he suffered from incontinence of urine; but, after a while, this symptom left him. On admission, his aspect was delicate, and his manner somewhat imbecile; all the movements of his limbs were weakened, and he complained of intense pain over the forehead. There was also slight paralysis of the left side of the face—the tongue being protruded to the right side; articulation was thick and indistinct; the pupils were dilated, and the right one was larger than the left. The pulse was 96, and soft. The tongue was coated. He was ordered iodide of potassium, with nitrate of potash and compound decoction of aloes, and ordinary diet, and porter. On the day after admission rigors came on, followed by profuse sweating, but this did not recur. The headache diminished. The pupils became equal, though very sluggish, and strength was recovered. Twelve days after admission he was out of bed, much stronger, and pain in the head had ceased. Moreover, the facial paralysis had almost, if it had not quite, disappeared, and the pupils took on more of activity. The alvine evacuations, however, were still, at times, passed involuntarily. Later on, the articulation grew more distinct, but slight paralysis of the muscles of deglutition subsisted. His imbecility of manner remained the same, and the difficulty as regarded swallowing continued to be considerable, but his general health appeared to improve.

At this time he was, unfortunately, removed from the hospital, and nothing further was heard of him.

EXTENSIVE SOFTENING OF THE RIGHT CEREBRAL HEMISPHERE; DISEASE OF THE LINING MEMBRANE OF THE KIDNEYS AND BLADDER; PROSTATIC ABSCESS.

*Case 121.*—James B., aged 35, a shoemaker, was admitted December 2nd, 1857. It appeared that three years previously he had had a "fit," when he lost his senses and bit his tongue. On recovery his speech was affected, and the right side of his body paralyzed, and so remained a few days. Ever since there had been numbness in that side. About one and a half year afterwards he experienced a sudden loss of power, with a tingling sensation in the left side whilst walking, and fell down. This feeling lasted only a few minutes. Three months before admission he had another (a third) attack, but did not lose his senses; experiencing tingling at the fingers of the right hand, which ran up the arm, and extended to the whole of the side of the body. He had never had rheumatic or scarlet fever, but at times had passed blood in the urine. He had often had pain in the left eyeball, and double vision.

\* For the details of this case I have to thank Dr. Allbutt of Leeds.

When admitted the left eyelid was quite closed, and the left eyeball turned outwards, and immovable except outwards and slightly upwards. The pupil was much dilated, but not influenced by light. As regards the right eye, the sight with it was said to be very "long," requiring objects to be placed far off, and its pupil was very inactive, but of natural size. Double vision often came on when both eyes were opened, at which time the sight was also very dim. He had no pain in the head, and the memory was unaffected, but he complained of deafness in the left ear; the senses of taste and smell were entire. He complained much of pricking sensations on picking up anything with the fingers of the right hand; of frequent jumping of the legs, so that he could then not walk or lie down; and the whole of the right side felt weak. There was decided weakness of the whole right side, but he could walk with the aid of a stick. The tongue was protruded in a straight line, and was furred; bowels confined. The urine was acid, and contained a slight amount of albumen. The heart's sounds were feeble and distinct, but no valvular bruit existed. The lungs appeared in all respects natural. Later on the urine would pass away involuntarily; at other times it was voided with great difficulty, and much pain over the pubic region was complained of. Blood and mucus globules appeared in the urine. He was treated by counter-irritation to the back, and the use of the iodide of potassium. The power of holding the water varied much; pain in the head came on, and also in the loins and back. Rigors set in at the beginning of January, with pains in the penis and left renal region, and was followed by semi-coma. The evacuations passed were involuntary, and he sank and died January 10th.

*Post-mortem Examination—Abdomen.*—The kidneys were natural as to their substance, but their pelvis and lining of the ureter and bladder were very inflamed and coated by recent fibrinous deposit, and the prostate contained a small abscess. *Cranium.*—The pia-mater was in places opaque. The brain generally was wet, and contained many vascular puncta. The posterior and outer part of the *left* cerebral hemisphere was in a very softened condition, and more vascular than other parts. The ventricles were large and full of fluid, and many gritty particles were found beneath the lining of the right ventricle, but few beneath that of the other ventricle. The vessels at the base of the brain were rather atheromatous. Other organs were natural. (10.)

SOFTENING OF FORNIX AND WHITE CENTRAL PARTS OF BRAIN; CARIES OF THE SPHENOID BONE; CHRONIC ABSCESS OF THIGH; COMA BEFORE DEATH.

*Case 122.*—Jane S., æt. 27, was admitted March 27th, 1863, in a very emaciated state. She had always had delicate health, but three years previously had a chronic abscess of the thigh, and the opening there made had never healed. About twelve days after admission she had a rigor, and immediately became unconscious, talking incoherently and incessantly for some hours, when she ceased to speak, but continued to move mouth and lips. She remained unconscious until death, which occurred March 30th.

*Post-mortem Examination—Thigh.*—The sinuous cavity was found amongst the muscles of the thigh connected with the opening above alluded to. The joints were healthy. *Thorax and Abdomen.*—The kidneys were much diseased. Other organs natural. *Cranium.*—The greater part of the body of the sphenoid was found to be carious, forming an abscess, at the upper wall of which was the pituitary body greatly enlarged. The surface of the brain was rather flattened, and the brain generally rather vascular. The fornix and neighbouring white central parts were softened.\* (85.)

SOFTENING OF THE CENTRAL WHITE PARTS AND CONGESTION OF THE BRAIN; EFFUSION INTO THE VENTRICLES; CARIES OF THE SPINE.

*Case 123.*—Andrew Wright, æt. 3, was admitted September 3rd, 1845, having been ill three weeks, with loss of

appetite and restlessness. He had had slight convulsions of the limbs, and twitchings of the muscles of the face; he had been very drowsy and thirsty, and often starting and at times screaming; his bowels had been much confined. On admission his pupils were very dilated, and acting imperfectly; he was sensible, and complained of much pain in the head; he was very drowsy, often rolling the head on the pillow; the thumbs were drawn into the palms; and twitchings of the face existed. In spite of treatment he became worse; the pupils became fixed, the breathing laborious; coma came on before death, which occurred September 10th.

*Post-mortem Examination—Cranium.*—The large veins at the upper part of the brain were much gorged; the pia-mater injected and the convolutions dry; the ventricles contained a large amount of clear fluid, and the fornix, posterior part of corpus-callosum and walls of the posterior and inferior horns of the lateral ventricles were softened and cream-like; a very slight amount of transparent lymph existed under the arachnoid membrane at the floor of the third ventricle. *Thorax and Abdomen.*—The lungs were slightly congested, and the left one contained a few patches like extravasation of blood; other organs natural. The body of the second dorsal vertebra was carious, and had an abscess connected with its anterior surface. (220.)

ON THE

### USE OF ERGOT OF RYE AND PHOSPHORUS IN CERTAIN HEAD AFFECTIONS SIMULATING BRAIN SOFTENING.

By H. R. HADDEN, M.D., F.R.C.S., Clonakilty.

THERE are few practitioners who have not met amongst their intellectual patients cases such as that which I am about to describe, and who will not acknowledge that they are anxious and intractable. The present remarks are thrown out in the hope that those who read them may be led, not only to test their soundness, but to publish the results; for it is not likely that a sufficient number of such cases would fall to one man's lot to form such a basis for deductions as would entitle them to any very general reception.

You are called to a patient, or he enters your study; his gait is unsteady and uncertain, not unfrequently he appears near-sighted, but on closer examination you find that the lids are partly closed, rather to compensate for dilated pupils, the result of an amaurotic condition of perhaps long standing; there is a restlessness about his manner, he shifts uneasily on his seat, his hands are scarcely a moment in the same position, his legs are crossed and re-crossed unceasingly, especially as he describes his case, which he does after an evident effort to collect himself for the task; but once begun he does it rather rapidly, till suddenly he is at a loss for a word, or memory fails; he becomes greatly agitated, rubs his forehead and seems rather vexed with himself; in vain you tell him it is of no consequence and ask him to proceed; he must remember it, and if he can't he'll tell you he will presently, *and so he will*, for, suddenly, when at some other part of his case he stops and gives you the missing link. He has been very intellectual, and instead of curbing a free horse he has spurred him; either he has been a follower of the good old maxim—"It is more blessed to give than to receive," and has worked hard intellectually and otherwise for the sake of others; or he has been selfishly ambitious and worked but to hoard up the results, which, like the miser with his coins, he arranges, re-arranges, and worships, all alone (this latter will I think be found the most intractable case). Some years ago, perhaps either from constant reading or some other cause, his sight began to fail, by-and-bye he is at a loss for a word and can't express himself as freely as usual, dates and names or some such things are hard to be remembered at the right time, yet he can call to mind with

\* For preparation of diseased sphenoid bone, see St. George's Hospital Catalogue, Series, ii., No. 40, A.

surprising minuteness the details of some little occurrence years ago; now he comes down to breakfast without his necktie or collar, he goes out without his hat—in fact he is subject to fits of absence of mind, and his friends get uneasy. It is all put down to stomachic derangement and sympathetic disturbance of the brain; he is dosed with Gregory's powder or some antibilious pills and bitters; some little temporary relief is obtained, a symptom is relieved for a little, but the real cause remains unmolested. At last there is some little unsteadiness of his gait, paralysis at once suggests itself to some intelligent friend, and a medical man is consulted; at once the over-worked brain is pointed out as the "fons et origo mali," but what is the matter with it? Threatened softening. A mild mercurial course is recommended; just because it is a brain affection; or the derivative treatment is tried; purgatives, acting on the lower bowel, are given freely and continuously; a blister is opened on the back of the neck and kept running; mustard foot-baths are recommended, all stimulants are interdicted, and total cessation from work enjoined. I am only describing what I have more than once done myself, but all to no purpose; no permanent advantage is gained, the mind becomes weaker, the gait more unsteady, and lesions (functional at least) of the chylipoetic and genito-urinary systems are more frequent, till at last the dreaded ramollissement with its melancholy train of symptoms ensues; but, is this unavoidable? or at least is the foregoing treatment, and the pathological principles on which it is based, such as will be most likely to delay the progress of the disease, if not to interrupt it? I think not. Let us now strive to unravel the pathology; and here I must speak with caution, for I have no post-mortem appearances to support me, nor is it likely I will, for in this country place, unfortunately, amongst the middle and lower classes to open a patient's head after death would be to put your own into very considerable danger of similar treatment. However, as I do not want to bring forward anything new on this point, it does not matter so much; all will agree that the result of the constant overwork was a proportionately constant congestion of the cerebral capillary circulation, which if relieved by judicious intervals of rest would have done little or no harm, but from being so constantly dilated the walls of the little vessels lose their elasticity, till at last, when the rest comes they are unable to regain their normal calibre, or to do their part in the propulsion of the blood, from which, be it remembered, the organ they supply is nourished; hence there is functional disturbance from mal-nutrition, merging slowly and fitfully but surely into organic disease. There is evidence enough of the disintegration of brain tissue in the phosphatic condition of the urine and elsewhere, but the nourishing fluid is moving too slowly and sluggishly to bring sufficient nourishment to repair the waste. Why? Because the capillaries are dilated and inelastic, and the very organ which is at fault is believed by many to play at least a very important part in endowing them with contractibility. Can this be remedied or relieved, and how? Will mercurial action do it? Scarcely, for stimulated absorption is not indicated. Will induced diversion of blood to and congestion of the capillaries of the rectum and elsewhere? Scarcely either, as although it may relieve those of the brain from tension in some degree, thus giving them a chance of contracting, it will not stimulate them to do so, or minister one whit more nutriment to the organs which preside over this function, although if the case be so recent that the contractibility of the capillaries is but slightly impaired, and its sources intact, the cause of the congestion being removed it may effect a cure; but the condition I have attempted to describe has gone beyond this.

To the experiments of Brown-Sequard on the influence of ergot of rye, belladonna, &c., on the capillary circulation of the cerebro-spinal system through its action on the sympathetic, I mainly owe, under Divine guidance, the treatment which the reading of them in THE MEDICAL PRESS AND CIRCULAR suggested to my mind, and which I put into practice shortly after in the first of the cases I am about to narrate, and which was based on the belief that ergot of rye caused the cerebro-spinal capillaries to contract.

This presumed power of ergot of rye I conceived would be a valuable aid in the treatment of the affection under consideration, and the result in the following case, and others which I may by-and-bye bring forward, I think go far to prove that it was:—

Early in 1864 I was called to see a clergyman of the Established Church, who held a high character for mental endowments, hard work, and usefulness. His age was fifty-six. He had been eight years ailing. The first departure from health was impaired vision, for which he was with The Hofrath in Germany. He believed he received much benefit, and certainly brought home a most favourable impression of his treatment. He returned in the year 1861, and twelve months after he first noticed the commencement of the train of symptoms I have tried to describe. Suffice it to say that he went through all the stages above described, and had from time to time all the symptoms, with others besides, and moreover underwent most of the treatment. When I saw him he had a train of symptoms which (if this occasional interruption were not taken into account) would certainly warrant one in believing that there was decided and hopeless brain softening. Indeed this had been diagnosed, and no wonder, for he could not walk alone out of doors, would make the most egregious mistakes in his toilet, and trembled and jerked all over as he sat striving to talk to you, at a loss for every second word—in fact, mentally and physically in a state which threatened shortly to give place to the paralysis, torpor, and somnolency, if not idiocy of the advanced stage of the disease; indeed he and his mother, for he was unmarried, had just returned from a neighbouring town to await these symptoms; but on inquiry I learned that there were almost perfectly lucid intervals, during which mind and body seemed nearly in health. This encouraged me, for I argued that if hopeless disintegration of nervous tissue had taken place these intervals could not occur. Capillary congestion of the cerebro-spinal system offered me a satisfactory solution, especially as I found that the attacks were always preceded by excited cardiac action and engorgement of the frontal and temporal veins. So I determined to make use of the information I had just gleaned from Brown-Sequard's experiments concerning the action of ergot just referred to. The following was the treatment I suggested, and which was carried out with a firmness and minute attention which I have never seen equalled:—

To have milk or cocoa with wholemeal bread and butter, and a little meat at breakfast; a glass of claret and a biscuit between it and an early dinner of roast or boiled meat, with vegetables sparingly, and two glasses more of claret; a light evening meal of either very weak tea, milk, or cocoa, and bread and butter; no supper.

His brain to be kept as much at rest as possible, taking care to keep him in complete ignorance of all parochial matters.

A perpetual blister which had been open for years over the vertebra prominens, to be kept gently discharging, all medicine except the following to be scrupulously discontinued:—

R. Ergotinæ grana duodecim.

Pulv. aloë cum canella.

Antim. sulphuret. precip. aa gr. xxiv.

Fiat massa. divide in pilulas viginti-quatuor; sumat unam ter in die.

R. Calcis hypophosphitis, ℥ij.

Acidi phosphor. dil. ℥iv.

Syrupi aurantii, ℥i.

Aquæ font. ad. ℥xij. misce sumat. drachmas quatuor ter in die cum pil. sing.

The antimonial was intended to control the cardiac excitement, the aloetic to stimulate the sluggish bowel, and the phosphatics to feed the enfeebled brain, while the ergotine exercised its hoped-for specific action on the capillaries. I should say that at this time his urine glistened with triple phosphates, the bulb of the urinometer being even to the naked eye thickly studded with them, while the field of the

microscope was crowded with beautifully formed crystals; he was also occasionally tinged with jaundice.

I will not delay to go through the necessarily slow progress of the case. Suffice it to say that at the end of three or four months he could and constantly did walk a mile or more together, once, twice, or three times a day, besides moving about at home with comfort; his gait was steady, he was seldom at a loss for a word, his memory was excellent, and his manner calm and composed. By degrees the aloetic was decreased, as it was less needed, while from time to time an occasional flag was met by an increase of the phosphates. Matters went on so, with occasional interruptions, till he reached a state of mental and physical health I never hoped for; he now began to enter very much into his parochial work, and by degrees so much so, that he knew everything pleasant and unpleasant which happened, and transacted a great deal of business both by writing and otherwise—too much indeed, as the sequel proves; and now came a train of symptoms and a course of conduct on my part, which I think was mistaken, and which I can only excuse by the fact of my having been in very ill-health myself.

He was suddenly seized one day, during the early part of which, and for some days previously, he had done much brain work, with an attack which the note sent for me stated was extremely like apoplexy. I saw him a few hours after; he was confused and altogether upset, but his pulse was quicker than usual; there was heat of skin and thirst, his tongue was furred, and he had a rigor some hours before; he complained of difficulty of swallowing, but on examining the throat no cause could be seen; after forty-eight hours it was plain that an abscess of very large size was forming in the left and anterior walls of the pharynx; it increased, causing great discomfort, and very serious constitutional disturbance, till there was a very considerable bulging of that side of the neck; but, owing to the depth of the matter and the intervening muscles, no fluctuation could be perceived externally. On the fifth day the finger when passed well down over the root of the tongue could detect a rounded fluctuating prominence to the left of and on a level with the root of the epiglottis. As matters were assuming a very serious aspect I determined to endeavour to make an opening at this spot, having first made his friends aware of the possibility of the matter rushing from the opening into the trachea, and suffocating him. I rolled paper round the blade of a sharp pointed curved bistoury to within about half an inch of its point, laid it flat on the palmar surface of my right index finger, and while I drew forward the tongue well with my left hand, passed it down till it reached the soft rounded prominence before alluded to, and then by the movements of the remainder of my hand succeeded in making an incision at least half an inch long, and so deep that I could bury the top of my finger in it, yet no matter came; I made the incision yet deeper, and then penetrated further by the use of my sharpened nail, but all to no purpose, when I desisted, rather discouraged, but determined to make an opening from without after he had recovered a little, but before half an hour thick fetid pus began to ooze from the incision, and before an hour had elapsed fully a pint had been brought up, to his entire relief, and mine also; the quantity of matter gradually decreased, and all healed up. The very serious brain disturbance which occurred at the commencement of this attack, and which was, I think, due to the circulatory excitement of the inflammation which resulted in the abscess, only partially subsided, for the relief of which I gave him James's powder, in fair doses; in continuing this treatment and losing sight of the ergot and phosphates I was, I now think, mistaken. Somehow or other I seemed to have lost confidence in it, and for a considerable period, now following, I combated the cerebral disturbance with the James's powder, turpentine enemata, sinapisms, &c., &c.; a train of digestive symptoms now arose, which I proceeded to treat with alterative aperients—pepsine, stomachics, &c., &c. Once or twice that I gave mercurials, they were evidently injurious, although I only used three grains of blue pill, with seven of compound rhubarb. I also tried very small quantities of brandy well

diluted after dinner to aid a weak digestion, with excessive flatulence, but it did mischief, too—the one depressing, the other exciting unduly the feeble brain. My attention had now, unfortunately, got diverted from the origin of the disease to its symptoms, and although I reverted occasionally to the ergot and phosphates, it was only fitfully to give it up again on every (I now think) unfounded charge of disagreement. Matters went on thus—the mind becoming more enfeebled, and the functions of the various organs more impaired; one after another the following symptoms arose and repeated themselves—viz., jaundice, constipation, retention of urine (evidently from loss of nervous presidency over the bladder), hiccup, the most severe I ever saw or heard (lasting continuously for days, loud enough to be heard across the street, and violent enough to convulse his whole body); and last of all, the most unprovoked, and, to him, fearfully distressing sexual excitement, with incessant erections. All these were, as they arose, treated and relieved for the time by their appropriate remedies, but the ergot and phosphates had, by this time, fallen into entire disuse, till, some weeks since, I was called to find him in a state infinitely worse than he had ever been—idiotic, knowing no one, shuffling and tossing about in his bed, muttering all the while to himself, every moment wanting to make water, but when the vessel was brought and the penis caught to direct the stream into it, the mere touch excited the whole sexual system into a frenzy, and back he plunged to discharge both urine and feces in his bed, with bursts of flatulence. He was, I thought, a wreck, and I was nonplused. However, my health having been restored by a trip to France, giving me a few weeks' rest, and my confidence in the ergot, &c., more than restored by my having tested it severely in several cases (one a most remarkable one, the patient having been a sufferer for nearly twenty-five years, and having undergone every conceivable treatment at the hands of the first men in the kingdom), I determined to revert with increased energy to my original treatment. His poor mother asked me if he could be removed to an asylum, or some such place, where he could have skilled nurses, and where she would be allowed to be constantly with him; but I said, "He cannot be removed now; the case is gloomy, very gloomy; but he may recover consciousness." Having stopped all depressing and aperient treatment, enemata, &c., I ordered the following:—

R. Ergotinae.

Pulv. aloes c canella.

Antimonij sulph. prec. ana. gr. xxij.

in pil xxiv. Sumat unam tertiiis horis.

R. Calcis hypophosphitis pxx.

Aqua aurantii ʒi.

ft. Haustus cum pilulo singulo sumend.

To have concentrated meat broths and claret liberally.

Next day consciousness was greatly restored, but easily lost, and all the other symptoms modified. Dr. Hadden, of Skibbereen, saw him with me, fell in completely with my original diagnosis, and advised the addition of one-eighth of a grain of alcoholic extract of nux vomica to each pill, which has proved of signal service in giving tone to the intestines and the muscular system. It is now some weeks since I saw him. (I should have said that after the first day the medicines were given only three times a day.) The accounts have been progressively improving, stating that his mental faculties have quite regained their balance again, and are not easily disturbed, but that he was still very weak. Ere yesterday his mother writes:—"Thanks to our gracious Lord, my dear son is going on favourably. He is stronger on his feet, and this day walked a while in the street without Mr. —'s arm. He passes a good deal of water during the night; it comes freely. During the day he has not nearly so many calls." And on enclosing the note to my uncle, he says:—"It is pleasant to find that he is doing so well, and the improvement which immediately followed the return to your former treatment shows that there can be no doubt of the accuracy of your diagnosis, and the propriety of your persevering steadily with it." I have

already spun this paper to so much beyond my original intention that I will not now refer to any other case. At some future time I hope, if the Lord will, to report the further history of this case, and give the details of others; meantime I would solicit the aid of my professional co-workers in sifting the matter, and if found worthy, placing it on the firm footing of experience. If the lamentable uncertainty of the science of medicine is ever to be dissipated it must be by "a long pull, a strong pull, and a pull altogether."

In conclusion, I would say that, for all I know, this treatment may have been conceived and carried out by some one else, but I am not aware of it, and it is not within my reach to find out. I lay no claim to originality for its own sake, and only seek to advance the cause of truth.

### A SUCCINCT HISTORY OF VACCINATION,

FROM THE YEAR 1796 TO THE YEAR 1866.

By W. H. SANDHAM, M.R.C.S., Cork.

MANY kings, emperors, and princes, lords, dukes, and earls, patriots and poets, lay and clerical, military, scientific, and literary celebrities have had statues and testimonials erected to perpetuate their memories; many of whom, when we trace back their history, should have been denounced as tyrants and heartless enemies of common humanity, who, to gain a miserable distinction, sacrificed every principle of honour, and placed their heels on the necks of friends, since proved true as steel; but there have been grand exceptions. The Medical Profession of Ireland, and all the world over to a man, must feel individually honoured by the latest, hardest-earned, and best deserved tribute to the genius and perseverance in the cause of humanity of the illustrious Jenner—namely, the passing of the Compulsory Vaccination Act for Ireland by Great Britain's Queen, Lords and Commons.

When Dr. Jenner commenced his observations and experiments the annual mortality from small-pox was—at Naples 16,000, 20,000 at Paris, and 30,000 in England. Variolous or small-pox inoculation was first introduced into England in 1721-4.

"Cow-pock and its anti-variolous powers have been known for ages in the greatest part of Holstein, especially in the eastern parts; but inoculation from one human subject to another was unknown until Jenner's publication."—(*Vide* "Report of the Medical Faculty of Kiel to the German Chancery of Copenhagen on Cow-pock in the Duchies of Schleswig and Holstein.")

Dr. Jenner made his first experiment of human vaccination on the 14th May, 1796. Dr. John Redmond Coxé first introduced it into America.—(*Vide* "Practical Observations, dedicated to Jenner in 1802.")

In 1806 the King and Queen's College of Physicians and the Royal College of Surgeons of Ireland were requested, by direction of his Majesty George III., to transmit to the Royal College of Physicians in London their observations and opinions upon the state of vaccine inoculation in Ireland. They did report, and strongly urged the promotion of vaccination.

The practice of vaccine inoculation was first introduced into Dublin early in 1801, the year it was determined there should be but one Imperial Parliament for the British islands.

The Cow-pock Institution, North Cope-street, Dublin, was established in 1804, under the patronage of the Earl of Hardwicke, and it is from this period we must date its general introduction to Ireland. This institution in 1804 vaccinated 578; in 1805, 1124; and in 1806, 1356 patients. The original "Vaccine Pock Institution," Golden-square, London, was established, and did good work, about the same time as the Dublin Institute. The Committee of the Royal College of Surgeons, Ireland, report that from the 25th Nov., 1800, to the 25th Nov., 1806, 11,005 were vac-

inated at the Dispensary for Infant Poor, 2831 at the Cow-pock Institute, making a total of 13,836, exclusive of those at hospitals and other places where no register was kept.

In 1806 a vaccine club held their meetings at the British Coffee-house, Charing-cross—William Devaynes, Esq., M.P., was chairman—where the post hoc and the propter hoc were considered, and they advocated vaccination.

The Cow-pock Institution was removed from North Cope-street to 56, Sackville-street in 1804, under the patronage of—

#### PHYSICIANS.

Joseph Clarke.

James Cleghorn

Thomas Evory.

#### SURGEONS.

George Stewart.

Ralph S. Obre.

Solomon Richards.

At this institution, from 1804 to 1807, 5122 were vaccinated.

The Committee of the Carlow Infirmary issued an address, pressing on every one to promote vaccination.

#### CEYLON.

In August, 1802, to June, 1806, 47,523, and in June of the latter year, 2490 were vaccinated.

#### INDIA.

From September, 1802, to May, 1805, 429,821 were vaccinated in the Presidency of Madras, of whom 2816 were subsequently inoculated with small-pox, *which they all resisted*. From September, 1805, to 31st August, 1806, 178,074 were vaccinated.

#### SCOTLAND.

The Vaccine Institution, Scotland, reports having, from 1801 to 1806, vaccinated 7140.

#### JAMAICA.

In 1807, 900 were vaccinated at Jamaica.

#### NEW ENGLAND.

In 1805, Dr. Spalding, of Portsmouth, New England, writes:—"The blessings of the cow-pock spread far and wide through this country."

#### THE DANISH DOMINIONS

Adopted it, and in the Islands of Ferroe, Iceland, and even Greenland, in 1802, 6849, and in 1805, 23,185 were vaccinated.—(*Vide Med. and Phys. Journal*, 1807.)

#### SILESIA.

In 1804, 24,319 persons were vaccinated; but, on account of the war in Germany, 17,316 were vaccinated in 1805 in Silesia, all of whom escaped the small-pox which broke out early in spring, and continued for the remainder of the year, and premiums were granted to persons who distinguished themselves in the practice of vaccination.—(*Vide Edin. Med. and Surg. Jour.*, No. 9.)

Dr. Willan properly says, "None should be inoculators who have not particularly attended to vaccination."

But Spain and Russia outdid all in their philanthropic efforts at this time to spread the practice of vaccination throughout the world.

You may read in the *Med. and Phys. Journal*, vol. 17, page 247, as follows:—"On the 31st Nov., 1803, an expedition sailed from Corunna, by order of the Spanish Court, under the direction of Dr. Francis Xavier Belamis, Surgeon Extraordinary to the King, and several members of the Faculty, conveying with them twenty-two children, selected for the preservation of the vaccine fluid, by successive inoculations during the voyage, which was undertaken for the sole purpose of establishing vaccine inoculation in all the possessions of the Crown of Spain situated beyond the seas, and in those of several other nations. They touched at the Canary Isles, Porto Rico, and at the Caraccas, when the expedition divided into two branches, one sailing to South America, under the sub-director Don Francis Salvani, the other, with the director Belamis, steered for the Havannah and thence to Yucatan. There a sub-division took place, the parties taking different routes, that they might propagate vaccination as widely as possible, and having made

very extensive circuits, they met at Mexico, whence they proceeded to the Philippine Islands, carrying with them twenty-six children from New Spain. Having propagated the specific in the islands, Belamts established the practice at Maçao and Canton; after which he embarked for Lisbon, where he arrived on the 15th of August. He stopped at St. Helena and prevailed on the *English* to adopt a practice which they had undervalued for eight years.

The other part of the expedition traversed South America; here were vaccinated 50,000 persons without one unfavourable result. They met at Santa Fe, and at the end of March, 1805, continued their journey in separate tracts over the remaining districts of the vice-royalty of Lima and on to Guayaquil. A correspondent has informed Mr. King of London of an expedition being set on foot by the Court of Petersburg, which had, when the account of its progress arrived, propagated vaccination through the vast territories of Siberia and Tartary, and was about to enter the northern boundary of China.

The most remarkable outbreak of small-pox of modern times occurred at Cork in 1855--56, when I (after having advocated house-to-house vaccination in a letter addressed to the *Cork Constitution*), was appointed visiting vaccinator for the city, and Archdeacon Kyle exerted himself beyond all praise to raise funds for benevolent individuals to carry it into effect. My report of that epidemic and the success attending vaccination was published in 1856, and the *Lancet* of the 16th of May, 1857, commented on it:—

“Some subjects there are which periodically turn up apparently for the sole purpose of affording the credulous and weak-minded opportunities for the display of their feebleness and self-sufficiency. Discredit of vaccination, and of its beneficial effects, is one of these subjects. It would not enhance our opinion of human discernment to recount the absurd and impossible effects that have been gravely discussed as attributable to its use, or to repeat the assertions of the gobemouches, that the benefits of vaccination are illusive, and its protective influence a delusion. For this reason, and on account of its intrinsic interest, we cite one of the most notable illustrations which has lately happened of the incalculable value of the great discovery of Jenner:—

“In the beginning of 1856, there broke out in the city of Cork an epidemic of small-pox. It raged throughout the city. The Archdeacon of Cork devoted his energies with noble philanthropy and wise forethought to collecting a fund for the appointment of a public vaccinator to visit from house to house. Dr. Sandham accepted the appointment, and fulfilled his task with admirable zeal. On the 8th of March, when he began his labours, the disease was raging in every lane and ally. In five weeks he vaccinated 2474 persons, and in six weeks after the commencement of his mission he traversed the whole city and found no case that needed vaccination. The energetic course stayed the plague which, during the previous two months, had gradually gained ground in spite of every effort, and attained a frightful intensity. From the report of Dr. Sandham we learn, that of those admitted into hospital one-third of the non-vaccinated died, of cases in the workhouse one-third also died, and the medical officers state that notwithstanding the exposure of all classes to the contagion, it never spread amongst any but the non-vaccinated, nor were any of the nurses or attendants affected.”

Since my report and the remarks of the *Lancet*, every man in the French army was vaccinated or re-vaccinated, and without one unpleasant result. But, as in Jenner's day so in mine, anti-vaccinators are to be found who tell the public—without any proof—that if they get their lovely babes vaccinated they will have horns before they die, or something much worse; so at this time up jumps Mr. John Gibbs, M.P., St. Leonard's-on-Sea, and addresses a letter to the *Brighton Examiner* attacking me and the Archdeacon of Cork in most unparliamentary language. He says:—“A Dr. Sandham, assisted by an Archdeacon, who had better have been trying to save souls, commenced an energetic course of vaccination, and in six weeks ‘stayed the plague.’ This is certainly a marvellous statement; but plain common-sense people who do not respect superstition—(nor facts)—even when clothed with the authority of ‘science,’ so-called, because it teaches not to know—will

ask what it really all means.” Again, Mr. Gibbs writes, “How absurd to expect protection by poking an animal poison on the point of an instrument into the arm!” In fine, Mr. Gibbs argues that every disease to which flesh is heir to is caused by vaccination.

Several controversial letters on the subject from both of us appeared in the *Brighton Examiner* of 1857. I was attacked by Mr. Gibbs, his friend Mr. T. W. Stowell, M.B., Church-street, Brighton, and a gentleman signing himself “Anti-vaccinator,” who I suspect to be a Cork solicitor, who may be an authority on legal matters, or be clever at making out a bill of costs, but certainly not an authority to guide the public on the question of vaccination.

However, after seventy years' perseverance by vaccinators, notwithstanding the opposition and ridicule heaped upon them from time to time, we have, as suggested by my report, and pressed for by the *Lancet*, and the many authorities quoted in this history, now in full force “a Compulsory Vaccination Act for Ireland.”

For the benefit of future vaccinators, I will wind up by quoting Dr. Willan's admirable description of perfect vaccination:—

“Vaccination is accounted perfect when recent lymph has been carefully inserted beneath the cuticle, in a person free from any contagious disease, and has produced a semi-transparent pearl-coloured vesicle, which, after the ninth day, is surrounded by a red areola, and afterwards terminating in a hard, dark-coloured scab. The form and structure of the vesicle is peculiar. Its base is circular, somewhat oval, with a diameter of about four lines on the tenth day. Till the end of the eighth day, its upper surface is uneven, being considerably more elevated at the margin than about the centre, and sometimes indented by one or two concentric furrows; but on the ninth or tenth day the surface becomes plane; and in a very few instances the central part is perfect. The margin is turgid, firm, shining, and round, so as often to extend a little beyond the line of the base. The vesicle consists internally of numerous little cells, filled with clear lymph, and communicating with each other. The areola, which is formed round the vesicle, is of an intense red colour. Its diameter differs in different persons from a quarter of an inch to two inches, and it is usually attended with a considerable tumour and hardness of the adjoining cellular membrane. On the eleventh and twelfth day, as the areola declines, the surface of the vesicle becomes brown in the centre, and less clear at the margin. The cuticle then begins to separate, and the fluid in the cells gradually concretes into a hard rounded scab of a reddish-brown colour. This scab becomes at length black, contracted, and dry, but it is not detached till after the twentieth day from the inoculation. It leaves a permanent circular cicatrix, about five lines in diameter, and a little depressed, the surface being marked with very minute pits or indentations, denoting the number of cells of which the vesicle had been composed.” “Cowpock is described by Mr. King as being on the third day like a fleabite, on the eighth a crystal, on the tenth a pearl, and on the twelfth a rose without a thorn.”

The clear transparent lymph should be taken from the unbroken, uninjured vesicle of a healthy child, at the latest on the eighth day after vaccination, but, in warm summer weather, may be best on the seventh day. If the lymph is allowed to be so old as to look opaque, purulent, or bloody, or even taken at the proper time mixed with the blood that escapes from treating the vesicle too roughly, it ought not to be used, much less depended upon, and it is my opinion, once the vesicle is developed and runs its course, as in the description of perfect vaccination quoted above, that this once secures the individual for life—as far as vaccination can do—without any future necessity for vaccination. I am entirely against vaccinating with the scab formed, even in the early stages, by the escape of the clear lymph.

Cork, 22nd Dec., 1866.

## Hospital Reports.

### SPECIAL REPORT ON THE TREATMENT OF CHOLERA BY VENOUS INJECTIONS.

LONDON HOSPITAL.

MR. LITTLE'S CASES.

(Continued from page 573, vol. ii., 1866.)

#### INJECTION OF SALINES; GREAT IMPROVEMENT; RECOVERY.

*Case 21 (No. 16 of the Table).*—A. B., aged 6, a small strumous-looking child, was brought to the hospital last September, in the morning. He had been seized with purging and vomiting of a rice-water character in the night; had had no previous diarrhoea, and had passed urine when he went to bed. On admission the choleraic expression was well marked; his lips and the skin round his eyes were blue; his pulse was perceptible, though weak and 130; respiration 40; temperature in the axilla 96.5. He was not yet in extreme collapse. During the forenoon he vomited and was purged frequently; he complained of great thirst, and drank cold and iced fluids freely.

He got gradually into extreme collapse, and at four P.M. was considered bad enough for saline injection—in fact those of the hospital staff who saw him considered his case hopeless. He was pulseless at the wrist, carotid feeble, the temperature in the axilla had fallen to 95, whilst in the rectum it was 101. He had 48 respirations a minute, was voiceless, livid, and gasping.

The median basilic was opened at the right elbow, and when fifteen ounces of the usual saline alcoholic fluid had been introduced by gravity, the improvement was so great that the operation was discontinued. The improvement was contemporaneous with the injection, the blueness first diminished, the breathing lessened in frequency and increased in depth, the pulse returned, and at the conclusion of the operation was good at only 100, respiration 40; voice natural. He had no rigor, but felt cold, although, as usual at this stage of treatment by venous injection, the temperature in the axilla was rising, and the internal temperature falling. Half an hour after the injection they were respectively 97 and 100, and the child gradually passed into a warm perspiration, took some beef-tea, which he kept down, and had no thirst.

Eight P.M. No vomiting, but has passed three rice-water stools since the operation. He is not so well as after the injection; his respiration is more frequent, but his pulse is still fair, and he is not livid; therefore he was not re-injected.

He took several spoonfuls of brandy and egg mixture, and beef-tea during the night, and slept pretty well.

In the morning, to our great surprise, he was sitting up in bed playing, quite convalescent, and clamouring for breakfast. Since the last report the bowels have acted three times; the last motion was coloured. He passed urine in the evening, and was kept on spoon diet for two days, then wine and chop were ordered, and he rapidly regained his strength.

In this case, as in others, the vomiting entirely ceased after the injection, and it is remarkable that there were not the slightest symptoms of reactionary fever, which at this period of the epidemic was very fatal to children. This case made a great impression on those who watched it, and converted one or two who were sceptical as to the benefits of the treatment, and who had previously stated it to be an utterly hopeless case. The speedy convalescence was partly due to the fact that the most urgent symptoms were not of long duration, as he was brought early to the hospi-

tal, and no large doses of powerful drugs had been previously administered.

*Case 22 (No. 18 of the Table).*—This man was injected, as the table shows, four times, each time with benefit, so much so as to make him talkative and expect to get well, but each time the improvement was only temporary. His stools were tinged with blood (rose-coloured) before the injection, so that although the warm fluid was a powerful stimulant, yet some fatal change had most likely taken place in the blood and a breaking up of the corpuscles.

#### PARIS HOSPITALS.

Several of our contemporaries have recently announced, as though it were a new fact, that this mode of treatment has recently been tried in Paris. Our résumé of the history of venous injections showed distinctly enough that the French had tried them at an early date, and since then there have not been wanting men in each epidemic as ready to avail themselves of this as of any other mode of combating disease.

In the epidemic of 1849 M. Briquet injected saline fluids into the veins of some cholera patients, and witnessed the temporary revival that usually follows. He was not, however, fortunate enough to have a permanent recovery.

Last year the method was again put in practice, not only in France, but we believe at St. Petersburg, and some other places, but the success has not been very encouraging.

In justice, however, to our confrères across the Channel, we may offer a summary of some of their cases:—

In the Hôpital Lariboisière, four patients under the care of M. Héraud were unsuccessfully injected last August. Of these, in one case only two ounces of fluid were injected, and the instrument employed was very imperfect. The patient lived three days after the injection.

In another case only five ounces were injected, and the operation was extended over about half an hour. Nevertheless, a considerable rally took place, moisture was again noticed in the eyes, and the patient spoke rationally, while the temperature in the axilla rose from 96° to 100°. A relapse shortly took place, and in two hours the patient died. The very small quantities injected in each of these cases would seem to remove them to altogether a different class from many we have related. In the remaining two much more fluid was employed. In one of them twenty-four ounces were injected into the veins of a patient who seemed to be *in articulo mortis*. An immediate rally followed; the eyelids recovered their motor power; the temperature evidently rose, but was not noted by the thermometer; he recovered the power of speech, and actually made his confession to the priest. In an hour, however, relapse came on, and he sank into a drowsy state and died.

In the last case reported at the Lariboisière about forty ounces of fluid were injected, the operation occupying about an hour. Moisture returned to the eyes, as in the other case, the colour returned to the lips, perspiration broke out over the face and chest, the temperature of the body rose, the surface was even described as *hot*. In every respect the patient seemed to be much better, and the mental activity and power of speech were so far restored that the man declined to sign a document presented to him for that purpose. In spite, however, of this great change a relapse soon took place, and he only lived about four hours longer.

These cases would seem to show that the amendment was in proportion to the quantity of fluid thrown into the circulation, and the last, especially, almost makes us regret that re-injection was not attempted.

To these we may add two cases communicated to the Academy of Medicine by M. Colson. In each of these a similar temporary benefit was noticed, but in both the symptoms returned, and the patients died. The liquid employed by M. Colson was as follows:—

R. Aq. distill. ℥xl.

Sodæ mur. ℥iiss.

Sodæ lactatis, ℥iiss.

Sodæ phos. ℥ss.

He injected it at a temperature of 107 deg. F., by means of an ordinary hydrocele syringe, into the median basilic vein. It is obvious that in none of the above cases has the method been carried out with the same perseverance and perfection of means as in those reported at the London Hospital.

To these cases we may add the particulars of the successful case recently brought before the Academy of Science by M. Lorain, and to which our contemporaries have drawn so much attention. It occurred in the St. Antoine Hospital, to which the patient was admitted on September 29, at 8 A.M., in a state of such hopeless collapse that none of the staff expected him to rally. The cramps were severe; he was pulseless and voiceless, with total suppression of urine. Temperature—32 degs. Centigrade in the mouth; 34 degs. C. in the axilla; and 37 degs. C. in the rectum. In the evening 400 grammes of water, at 40 degs. Cent., were injected into the veins. A stronger impulse of the heart immediately succeeded; the respiration became less oppressed, and the thermometer in the mouth, which had fallen during the day till it was only 26·8, just before the operation rose to 30. The patient then spoke. Two hours and a half afterwards he was sleeping calmly, and the surface was warm and bedewed with perspiration. Three hours later the thermometer in the axilla was 34·8 C. The patient was now awake, restless, and he vomited twice. The next morning he sat up in a chair, but no urine was yet passed, and the pulse remained imperceptible. Temperature of mouth 35·9, of axilla 34·6, of rectum 37·8 Cent. He continued to improve, and the third day after injection passed upwards of two pints of urine. The temperature was now 36·8 in the mouth, 36 in the axilla, and 37·2 Cent. in the rectum.

Having now reported in full a large number of cases in London, and briefly referred to many others at home and abroad, we shall, in our next article, conclude this report with a few of the deductions to be drawn from the experiences we have recorded.

## ST. VINCENT'S HOSPITAL.

### ABSTRACT OF A CLINICAL LECTURE UPON A CASE OF FRACTURE OF THE PELVIS.

By FRANCIS B. QUINLAN, M.D., T.C.D.,

MEDICAL ADVISER TO THE HOSPITAL, AND PROFESSOR OF MATERIA MEDICA TO THE CATHOLIC UNIVERSITY.

AFTER some preliminary observations upon the anatomy of the bones of the pelvis, their articulations and bonds of union, and the relations of the soft parts surrounding and contained within that cavity, Dr. Quinlan said—"The specimens upon the table were taken from the body of the patient A. B., a female, aged 35, No. 3, St. Mary's ward, who upon the 18th of November was knocked down upon the footpath and run over by a runaway horse yoked to a heavy country cart, which, however, was empty at the time of the accident. As she lay partly upon the right side, the wheel passed over the left anterior superior spinous process and down across the lower part of the abdomen. I saw her immediately after the accident, and perceiving by her collapsed appearance that she had met with some grave internal injury, had her removed to St. Vincent's Hospital. Her first symptoms were those of great weakness, for which stimulants were freely administered; and when she had rallied enough to allow of examination, it was found that there was a lacerated wound about four inches long extending across the hypogastric region, and through the mons veneris; this wound was of a semi-lunar shape, with the convexity downwards, and laid bare the tendon of the external oblique; but, as might be expected from its character, the hæmorrhage was not considerable. A large ecchymosis marked the track of the wheel over the left side, and a corresponding one on the right side showed how the right great trochanter had been violently pressed against the footpath. Examining further I found that the left anterior superior

spinous process was quite moveable and yielded an indistinct crepitus. The right foot was everted, but there was no difference of length, or crepitus on rotating the femur. These symptoms and the circumstances of the accident caused me to apprehend the occurrence of fracture of the left side of the pelvis, with probably a corresponding counter-fracture of the right. Later in the evening she was seen in consultation by Dr. O'Ferrall, who kindly visited her daily during the rest of her illness. He at once pronounced the existence of the fracture and counter-fracture to which I have alluded; and at his suggestion I introduced a catheter and drew off eight ounces of natural coloured urine without any trace of blood. There was no desire to pass urine; on the contrary, for about forty-eight hours there was that inactivity of the bladder so often observed in severe injuries of the pelvis and its neighbourhood. These circumstances caused us to form a rather confident opinion that the bladder was not injured, as it would have very likely been had it been full at the time of the accident. It is not quite so easy to decide this point as might at first sight appear; and above all the mere presence or absence of blood in the urine is not to be relied upon. The quietude of the bladder, the quantity of urine, and in a secondary degree the absence of blood were the reassuring circumstances in this case. Had the bladder been ruptured the rent would in all probability have been upon the posterior surface of the top of the fundus.

"The patient continued extremely weak, and as there was now some irritability of the stomach, wine mixed with a little brandy was administered during the night; she was kept in a comfortable position, and the abdomen was well stuped and poulticed. Upon the following morning reaction was well established, and in view of the probable occurrence of peritoneal symptoms, calomel and opium in very small doses were commenced. The stimulants, according as required, along with beef-tea and other suitable nourishment, were continued. The right thigh and iliac region were much swelled and beginning to become œdematous.

"Rather circumscribed peritonitis, commencing in the right iliac fossa, set in and was combated by leeching and stuping; the swelling and œdema increased, and ended in the formation of deep-seated matter in the iliac right fossa and thigh, but not situated in such a manner as to permit of direct surgical interference. These symptoms were treated, from day to day, as they arose; and the patient's strength was carefully maintained by nourishment and the judicious use of stimulants. About the eighth day she began to improve, and continued to do so for some days. About the eleventh or twelfth, that form of pelvic cellulitis, so often observed in these injuries, set in with its usual accompaniments of quick weak pulse, brown typhoid tongue, and general depression of the vital power. The stimulants were now freely employed; and, upon the suggestion of Dr. O'Ferrall, champagne and also strong tea were had recourse to. She gradually, however, became weaker and got drowsy, and finally died of asthenia upon the morning of the eighteenth day after the accident.

"The post-mortem examination was carefully made about twenty-four hours after death by Mr. W. H. O'Leary, Assistant-Surgeon to the hospital. Upon opening the abdomen we found a good deal of severe localized peritonitis in the right iliac fossa, in which also there was a large fluctuating swelling underneath the iliac fascia, to which the cæcum was adherent; the cæcum itself was inflamed and of a dark colour, but there was no communication between its cavity and the interior of the swelling. Laying open the latter, we found a great deposit of purulent matter, which we traced upwards along the psoas muscle as high as the fourth lumbar vertebra, and downwards along the sheath of vessels nearly half-way down the thigh, and inwards to a fracture of the os pubis, which will be presently described. In this cavity, in addition to pus, there was some aplastic lymph, and a good deal of ecchymosed blood. There was also a quantity of ecchymosed blood underneath the peritoneum along the right ilio-peritoneal line, above and inside the right acetabulum, showing that the cart-wheel after passing over the front of the left ala of the ilium had come down upon

this part. We next examined the intestines, particularly the rectum, but found no injury. The uterus and vagina were also safe. Turning to the bladder—to test the validity of our belief that it was not injured—we filled it with water with a catheter and syringe, and removing the catheter, and stopping the meatus with the finger, pressed upon the fundus and found the bladder and urethra perfectly water-tight. Turning now from the soft parts to the pelvic bones, we found an amount of injury greater even than we had expected. In the left os innominatum there was a fracture commencing beneath the anterior inferior spinous process, and extending to a point about an inch behind the anterior superior spinous process, breaking the piece off, and another fracture commencing about an inch in front of the posterior superior spinous process, and running into the left synchondrosis. In the right os innominatum, where the counter-fracture had occurred, there was a longitudinal fracture, commencing at the upper and outer part of the obturator foramen, extending backwards through the acetabulum and the ala of the ilium to the crest, at a point about two inches in front of the posterior superior spinous process. From the centre of this fracture there was another extending through the ala of the ilium and the anterior superior spinous process. Turning to the acetabulum we observed the great longitudinal fracture, already described, passing through this cavity in a line slightly above its notch. From this there branched off a fracture of the shell of the acetabulum, running across the whole cavity. The cartilage of the head of the femur opposite these two fractures was eroded, and the cartilage surrounding the erosions was very vascular. Turning now to the right pubal ramus we found two fractures—one of the thin portion of the descending ramus of the pubis, a quarter of an inch above the point of fetal union; and the other of the ascending ramus of the ischium where it joins the tuber. Lastly, there was a dislocation of the symphysis pubis, the right pubis being dislocated forward and slightly upwards, the inter-articular cartilage remaining attached to the left pubis, and having still connected with it a fragment of the right pubic bone. The sacrum and coccyx were uninjured. The dislocation of the symphysis pubis was not observed during life—a circumstance which was probably partly owing to the œdema, and partly because, having once ascertained the existence of the fracture and counter-fracture, we did not make any further examination into the details, which, however interesting in a mere diagnostic point of view, could have done no good to the patient, and would have certainly hastened the supervention of the pelvic cellulitis, which was the immediate cause of death.

“Reviewing all the circumstances, we must perceive the irrecoverable nature of this case from its very outset. Looking to the extensive osseous injuries, we cannot but be surprised that none of the pelvic viscera were injured. This is partly owing to the fact that no sharp point of bone was directed towards the pelvic cavity, and partly because these viscera were guarded more or less by the osseous structures. The only one directly exposed to the wheel was the bladder, and, had it been full, it would most probably have been ruptured.

“The extensive counter-fracture in the right os innominatum appears to me to have been produced by the acetabulum being violently driven against the head of the right femur, which, through the medium of the right trochanter resting upon the ground, acted as an upright wedge, and “stove in” the right side of the pelvis; a belief which is strengthened by the ecchymosis along the right ilio-pectoral line. An instance of this is related by Sir Astley Cooper in his “Surgical Essays,” and another by Mr. Earle, in which the lines of fracture diverging from the acetabulum followed those of fetal union. Nothing of this latter kind occurred in the present case, probably on account of the age of the patient. Owing to the complete eversion of the right foot, fracture of the neck of the femur might have been suspected; the absence, however, of crepitus or shortening, and the perfect semicircular rotation of the right trochanter easily decided this point in the negative. This eversion was simply owing to temporary paralysis of the rotator muscles of the right

thigh, produced by the injury, and is frequently observed in severe bruises of the hip, unattended by fracture of the neck of the femur.

“Mr. Travers has recorded a case of fracture running into the acetabulum in which there was at first no shortening of the thigh-bone, but in which gradual shortening subsequently took place—a circumstance which he attributed to secondary changes in the head of the femur by absorption of the articular cartilage and eburation. In the present instance the vascularity and erosion of the cartilage of the head of the right femur, opposite the fractures, might lead us to suppose that this process had commenced.

“The pathological examination of the abscess appears to justify the opinion that, during life, it could not have been evacuated. It could only have been reached through the thigh; and, considering the nature of the communication between the femoral and iliac deposits of pus, I doubt whether such a proceeding would have been effectual as regards the deposit in the iliac fossa, which was the principal one.

“Lastly, when we look at the circular arched shape of the articulated pelvis, we perceive what force must be required to crush it in—in fact, the accident is generally caused by the sufferer being run over, crushed between two railway buffers, or some other such great violence. When, however, the pelvis is crushed in, we see how naturally a serious fracture of one side is accompanied by a counter-fracture of the other. This arched shape gives to the pelvis a great power of resisting violence; but when the violence is of such intensity as to overcome the resisting power of the arch, the resulting lesions are of course proportionately serious.”

## Reviews.

### ON DISEASE OF THE RIGHT SIDE OF THE HEART.

By T. M. DALDY, M.D. London: Bell and Daldy.

THE author of this small but thoughtful essay has lighted upon a subject hitherto little regarded, and consequently had to draw principally upon his own clinical experience. He believes that the right heart, and more especially the auricle, is liable to a deterioration of its muscular structure, which gives rise to numerous well-defined disordered states of health, and which is essentially different from fatty degeneration. Dr. Daldy has for many years studied the subject, and here lays before the profession the conclusions to which he has arrived, in so compact a form that the busy practitioner may easily find time to read his little work. We have perused every page more than once, and if not quite prepared to endorse all the author's ideas, we can honestly advise all our readers to follow our example.

Having said thus much, it will perhaps be but just to follow Dr. Daldy through the several propositions he lays down.

First of all, he traces to feebleness of the right heart, and especially its auricle, many cases of dyspnoea, and even of angina pectoris, and he would attribute to this condition the powerful effect that certain emotions sometimes exercise on the circulation. The diagnostic signs of this condition he considers to be dullness on percussion to the right of the junction of the ziphoid cartilage with the lower third of the sternum, and propagation of the heart sounds towards the right clavicle. These signs, which should of course coincide with derangement of some part of the circulation, Dr. Daldy thinks are due to an abnormal distension of the right auricle, and this distension is caused by a deteriorated state of its muscular structure, which deprives it of the power of emptying it prior to the fresh supply of blood being on the point of entering. The pathological condition of the auricle is that its muscular structure is reduced to a state “something like elastic tissue (not fatty degeneration),” and here we encounter what is, perhaps, the weak point of the argument, for the author acknowledges that it is almost impossible to demonstrate post-mortem the condition referred to. It is, indeed, fair to remark that a dilatable rather than a dilated auricle would sufficiently answer the purpose of the reasoning offered us; and it is easy enough to imagine that abnormal distension may occur under unusual pressure. This, however, would be a less grave, because less persistent, state than the “habitually distended right auricle,” to which Dr. Daldy more than once refers. It has certainly seemed to us that the temporary lesion might be more frequent than the

permanent, if, as Dr. Daldy asserts, the deterioration of the structure is not fatty degeneration, and, indeed, cannot yet be exactly defined. This would be very hopeful in a prognostic view.

Dr. Daldy has met with instances of this disease which lead him to believe that it is hereditary, and even to be traced through two or three generations.

We now pass to the results to which this condition gives rise.

Cases of congestive headache, vertigo, and even softening of the brain, and mania, are traced by our author to the impediment offered by a distended auricle to the return of the blood through the superior cava.

The symptoms so often called determination of blood to the head would, in this view, assume an altogether different aspect, being produced, not by an actual supply of larger amount, but by the impediment to the return presented by the auricle being unable to receive the contents of the cava, on account of its not having discharged itself of its previous supply. In another class of cases, the effects of a stimulant would be equally beneficial in certain cases of syncope, whether there were actual deficient supply of blood to the brain, or, as Dr. Daldy says, impeded return.

We have no desire to extract all the valuable remarks respecting such difficult subjects as softening of the brain and mania, and shall therefore only state that, to an engorgement produced in the same manner Dr. Daldy thinks may be traced many cases of organic cerebral mischief, and that his statements are well worthy of attentive study.

In respect to treatment, allusion is made to the light atmosphere of great elevations enabling the patient to enjoy exercise. Other hygienic and dietetic counsels are offered, and then the "little as possible ruffled mind" is described as the "grand factor of comfort to persons labouring under deteriorated heart-structure;" and further allusion is made to the "mental erosion, resulting from life's scramble either for existence or distinction." We can most thoroughly corroborate this from considerable experience, and should be glad to see the subject more extensively treated. The wear and tear of modern life has, indeed, been frequently described as a cause of disease; but we doubt if even yet carping care, violent emotion, or that wretched state of worry in which too many of our patients pass too large a share of their time, is not much oftener than is believed the origin of numerous cases commonly described as heart disease. Certain we are that either will aggravate disease of the heart where it already exists.

Of drugs, our author does not name any. To diminish the quantity of blood sent to the right side of the heart, he purges with German Pullna water. He also recommends the habitual use of Vichy water to neutralise excess of acid, determine to the kidneys, &c.

To increase muscular tone he relies upon iron.

The use of stimulants is cautiously treated. Dr. Daldy thinks a certain amount of wine beneficial, but believes it should be taken only in small quantities at a time.

"I have," he writes, "arrived at the conclusion that wine is almost an article of necessity to these patients; but that if they require three glasses during the day it should be taken at three separate periods. The condition is comparable to that of a drooping plant, which requires a small quantity of water frequently, but if you give it too much, at any one time, you seriously impair its vitality."

#### REPORT TO THE CORPORATION OF DUBLIN ON THE OUTBREAK OF CHOLERA, 1866. By E. D. MAPOTHER, M.D., Medical Officer of Health. Pp. 63. Dublin. 1867.

In this report, from which we can find space for only a few extracts, Dr. Mapother avows himself a contagionist, but explains two other conditions which must concur in order to spread cholera. The first case he traces from an infected street in Liverpool to a room in Dublin, where the importer and three relatives died. In the ten days following this, six other persons with the disease upon them arrived in Dublin, and the contagion then spread so extensively that in a large city the difficulties of tracing it became insurmountable. He explains the greater mildness of the disease, when the infection is through the medium of air, by the greater dilution which the germs undergo. He quotes numerous examples of the communicability by water, and gives the following instances relating to the vicinity of this city:—

"In Swords, a little town of some 1400 people, 65 cases of cholera occurred in seven weeks. The water supply was from

an unprotected well, subject to great defilement, as I witnessed. There was the greatest difficulty in isolating the patients or getting them to go to the hospital, but as brandy was given out there was no difficulty in ascertaining when and where the cases arose. The sanitary state of the place has been greatly bettered, owing to the representations of Dr. Davys.

"In the village of Crumlin, out of the 165 inhabitants, 46 were seized with cholera or choleric diarrhoea. A single and most superficial pump is the sole water supply, and its produce is stinking and often muddy, as Dr. R. P. White informs me.

"Kingstown suffered far more than Dublin in proportion to the population, and at least one of the promoting circumstances is a wretched supply of water, exclusively by wells. After two cases of cholera, one of which was fatal, had occurred in the house of a friend of mine, he poured a quantity of carbolic acid into the sewer, and found that the water of the adjoining well tasted of that substance for many weeks after. It is almost certain that the sewage had in the same way percolated before the appearance of the cholera."

Of other media, he says:—

"The clothes of some cholera patients, who had been in one of the hospitals last August, were sent to be washed by a woman in Chamber-street, where the disease had not been previously, and in three days she was seized with cholera, which proved fatal to her and to a man residing in the same house, and spread extensively in that street, which is built along the Poddle."

"No death by cholera has occurred since the 28th December, and it appears to be for the present extinguished. During the 23 weeks it lasted, it destroyed 863 residents of our city, and 52 other persons brought in with the disease died in Dublin hospitals; if their deaths were registered in their respective localities, the mortality of some suburban districts would be relatively much higher than that of Dublin."

The cases of cholera, and of diarrhoea for 12 weeks before the outbreak, and during it as well as the diarrhoea, temperature and rainfall of the corresponding weeks in 1865 and 1864 are arranged in a tabular form. In the 1849 epidemic, out of a smaller population, we lost 1664; and in the most fatal month, June, 477 persons. In October, 1866, 268 persons died, and that month afforded the highest mortality. The late has been the most fatal of the epidemics in many Continental cities. "In my report for August I stated that the three following conditions should concur for the development of the cholera:—First, communication with those already sick; second, the unhealthiness of the body, which overcrowded rooms, bad food, intemperance, impure air, or uncleanness produces; the third condition is purely local, consisting in a porous undrained soil, in which excremental matter putrefies. I will offer evidence of the truth of this statement, as your conviction will mainly influence the steps which are advisable in order to prevent the renewal of the pestilence in spring.

"First—Communication with the sick was clearly traced in the earliest cases, but in a constantly intermingling population, and with such variety of media of infection as water, air, and clothes, it soon became impossible, as is also the case with fever, scarlatina, and other catching maladies. Exclusion by quarantine being impracticable, as persons coming from an infected place may import the disease although they themselves were not perceptibly attacked, our safety lies in disinfection.

"Second—The well-fed, well-lodged, and cleanly, and, consequently, healthy people, almost altogether escaped; there is, therefore, great need for the exercise of benevolence, and in raising the healthiness of the poor the affluent protect themselves. It may be fairly supposed that our remaining population are to some degree insusceptible of the disease.

"Third—Dampness and Foulness of Soil.—Suspecting that the malaria thus emitted conducted to cholera, I traced on a map of the city the long-forgotten streams and pools which are delineated on the plans of Dublin, by Speed, in 1610, and Rocque in 1756, and also marked the houses where all the deaths by the disease had occurred. It appears that cholera has almost exclusively fixed on houses built on these ill-drained sites, or placed close to the canals and other stagnant waters."

Some very interesting results are given. The space on which the house in City-quay, where the first case occurred, was fifty years ago a dock. The Poddle, Camac, Bradogue, and Tongue rivers, and the ditch surrounding the city walls, have been the great lines of the disease; in fact, almost every case can be shown to have been in houses built over such unsuspected sources of danger.

"The remedies are, the perfection of our drainage and the passing of a building act (such as English cities enjoy) to prevent speculators erecting houses on any site or in any way which costs least. In but four of the hundreds of our infected towns did the disease survive the cold of January, 1850, and they may have been re-infected. This fact, and the records of other cities in former epidemics, make me hopeful of immunity this year. However, besides the preventative steps alluded to, and continued vigilance on the part of the sanitary inspectors, I would advise, while the disease is at least dormant, that the refuse receptacles of all houses visited by cholera should be disinfected with carbolic acid and copperas, and that as many as possible of the house drains and main sewers in the city should be flushed simultaneously at stated periods."

The instructions for disinfection and isolation of patients are detailed fully, but do not seem to differ from those elsewhere employed, except in the provision of refuges for the families of those attacked, and a hot-air disinfecting chamber, which, however, from various causes, was not ready till some days after the last case had occurred. It will be used for purifying the fomites of other contagious diseases.

In a report addressed to non-professional persons, he does not, of course, enter into the proximate cause or symptomatology of the disease, but he leans to the belief that the cholera poison is organised, the more so, as it escapes the charcoal filter unaltered, whereas if it were merely a chemical compound, some change would be induced by oxidation. He appeals to the discovery of pus cells in the air of the eye ward at Prague, which had spread purulent ophthalmia, to support the idea that the cholera germ, even if dry, may regain vitality when applied to the alimentary mucous surface. In our columns, some months ago, Dr. Mapother asserted that, in cholera, the sympathetic system was excited probably in a reflex way by the irritation of the mucous surface. As the sympathetic system is the great controlling power over contraction of involuntary muscular fibre, especially the vaso-motor part of it, a profound impression upon it would induce contraction of all the capillaries and necessary cessation of all cell changes and the liberation of heat. It is impossible to believe that the drain of fluid (which in many cases in the late epidemic has been very slight), and consequent thickness of the blood would rapidly lead to the collapsed condition indicated by the shrivelling of the extremities and the stoppage of those functions dependent on the circulation, secretion, absorption, and the production of heat. The production of urine and bile are notably by cell action, and ceases therefore in cholera, but the drain from the skin and intestinal surface may be regarded as exhalations, especially if it be true that the epithelium of the latter is cast off early in the disease.

He noticed also that the pupil was dilated in the great majority of cases of cholera, and that the fact indicated increased action of the sympathetic, as it likewise does when worms in the intestines afford the exciting cause.

**ON DISEASES OF THE VEINS, HÆMORRHOIDAL TUMOURS, AND OTHER AFFECTIONS OF THE RECTUM.** Entirely re-written. By HENRY LEE, F.R.C.S., Surgeon to St. George's Hospital. Second edition. Pp. 190. London: Churchill and Sons. 1866.

MR. HENRY LEE has been so long before the profession as an original writer and an accomplished surgeon, that little more is necessary than to announce the second edition of the present work in order to insure for it a cordial welcome. But as some of our medical brethren, and especially some of the younger among them, may be unacquainted with Mr. Lee's contributions to surgery, we may take the opportunity of mentioning that the work is divided into two parts, the first consisting of a Treatise on Diseases of the Veins, and the second of an Essay on Diseases of the Rectum. The first Essay on the Treatment of Hæmorrhoidal Tumours was published in 1848, and the first edition of the "Diseases of the Veins" was published in 1850, having been the subject of the Jacksonian Prize Essay for the previous year. Although at first sight the different subjects which occupy the volume do not appear to be necessarily connected with one another, yet the diseases of veins form an appropriate point of departure for the consideration of hæmorrhoidal tumours, and thence to other affections of the rectum. The plan of treating piles with nitric acid, originating with Mr. Houston, but advocated and adopted by Mr. Lee, has been widely appreciated since the publication of Mr. Lee's treatise in 1848. We feel that it would be superfluous in us to do more than to announce the appearance of the present edition, and cordially to commend it to professional notice.

WEDNESDAY, JANUARY 9, 1867.

### SPECIAL HOSPITALS.

THE multiplication of what are called Special Hospitals is a subject which is now engaging much attention on the part both of the profession and of the public. The former are concerned, from the fact that many of our brethren are either connected with such institutions, or are anxious to become so, and the latter are beginning to take an interest in the question because it is pressed upon them by many of the Medical Officers of the General Hospitals. The practical point now to be decided appears to be whether physicians and surgeons who accept appointments at the Special Hospitals shall be allowed to continue their connection with General Hospitals, or whether the governing bodies of the latter institutions shall not be empowered to insist that the Medical Officers who held both appointments shall resign one or other of the posts which they hold.

As to the broad question existing between General and Special Hospitals, there is, as is usual in matters of controversy, much to be said on both sides. On the one hand it may be urged that the General Hospitals are so arranged that they are capable of receiving and of treating all the diseases to which human nature is liable, and that the Medical Officers who are appointed to take charge of the patients may be considered to have given sufficient evidence of their respectability and of their professional attainments, and that the fact of their election to such offices may be received by the public as a guarantee of their competency. It is true there may have been a time when hospital medical appointments were made rather on the ground of personal and class interests than of distinguished ability, but such a time has long passed away, and it may fairly be asserted that the present Governors of our General Hospitals are actuated only by disinterested motives in the choice of the Medical Officers, and that they conscientiously endeavour to secure the best occupants for the vacant places. We entirely repudiate the idea that deserving candidates are ever rejected from impure motives, although it may be true that the best man is not always successful.

But, on the other hand, there are obviously many classes of disease which cannot well be treated in the General Hospitals, either from the deficient arrangements of the buildings or from the peculiarities of the diseases themselves. Thus, for instance, lunatics cannot be conveniently received in General Hospitals in consequence of the chronic form which the malady often assumes, and from the injurious influence which might be exercised by such cases over

the rest of the patients, and it would be inexpedient and unsafe to admit small-pox and other contagious diseases into the general wards, or to mingle children with adults. Hence there can be very little question that insanity ought to be treated in Special Hospitals and Asylums; that small-pox and similar affections should be treated separately from cases of ordinary disease, and that lying-in women should be received in distinct wards; and very plausible arguments may be adduced in favour of treating children apart from adults, and of appropriating particular buildings for the treatment of diseases of the eye. Then, again, there can be no doubt that certain forms of disease are properly confided to the treatment of Medical Officers possessing special attainments, and that, as in the instance of the eye, peculiar dexterity is attained by surgeons devoting their abilities to the treatment of the diseases or accidents befalling that organ.

But while the Profession fully admits that what is called specialism in the cases we have just adduced is not only excusable but desirable in the interests of medical and surgical science, it is evident that the minute subdivision of disease into a multitude of distinct branches must tend to destroy or to impair that system of studying disease as a whole, which ought to be the prime object of every true disciple of the healing art. The heart and lungs, for instance, are so intimately connected in their anatomical and physiological relations that the treatment of the diseases of the one must necessarily involve, in very many cases, that of the other; and it would be as unphilosophical to institute separate establishments for the treatment of cardiac and pulmonary complaints as it would be to establish hospitals respectively for the treatment of diseases of the duodenum, the jejunum, and the ileum.

Again, it is necessary to examine every case of the establishment of a Special Hospital on its own merits. Many of these institutions are really merely private concerns, got up for personal objects, and without being subject to any of these controlling influences which, in a great measure, secure in public charities the respectability of the Medical Officers, and it is not unusual for persons so self-appointed to claim for themselves a more abundant measure of skill in treating special diseases than falls to the lot of their brethren. These are some of the abuses of the Special Hospital system, and we are not sorry that the subject has been ventilated, although we strongly suspect that in some instances personal feelings have done something to dictate the opinions which have been expressed, and that the old adage, "two of a trade can never agree," may, even in the professional contest now raging, find a not inappropriate exemplification.

## YELLOW FEVER.

ALTHOUGH it would appear that yellow fever does not find in this country a congenial soil for its development and propagation, it has been raging with great severity of late in some of the West India islands, and the last accounts relate a fearful epidemic of the disease among our troops in Demerara. Several ships coming from infected islands or places have reached our shores, and some have had on board patients suffering from the disease; but hitherto, so far as we are aware, the infection has not been communicated to any of the inhabitants of our islands. It would appear, indeed, that there exist in the West Indies and on the adjacent mainland climatic or local influences favourable to the origin and spread of yellow fever, but which are happily absent in our own country. Thus we find that while the malady periodically breaks out in the countries to which we refer, it is unknown as an indigenous scourge in Great Britain, and even when accidentally introduced, it fails to find a soil congenial to its extension. Our home Government is probably by this time convinced of the inutility of quarantine regulations in the case of yellow fever, and it is unlikely that the passengers of a ship coming from the West Indies will again be subjected to the hardships and inconvenience of lying for many days in the wintry season off the Isle of Wight, because some cases of the pestilence had occurred among the crew.

The accounts received from Demerara, however, are of a very painful description, and the more so because we find that in an article of the *Demerara Royal Gazette* blame is thrown upon the Garrison Medical Officer for not advising or consenting to the removal of the troops, among whom the disease prevailed, and to whom, as we understand, it was entirely confined. Whatever may have been the cause, the results have been most disastrous—the troops, it is said, having been more than decimated, and those who have been spared being described as in a most deplorable condition. The circumstance that the soldiers alone have suffered would seem to prove either that the locality where the garrison is situated is deficient in its sanitary arrangements, or that the troops themselves have been rendered liable to the infection by some constitutional predisposition. Both these causes may probably have contributed to the deplorable result; but the information now eagerly sought for is that relating to the conduct of the military authorities in not at once removing the soldiers from the infected spot to a more healthy locality. From some letters in the newspapers, it would appear that the site of the garrison at Demerara is not unhealthy, and that the disease must be traced to other causes than mere insalubrity of locality; but on these and other points we shall probably soon

receive more definite intelligence than that which we at present possess, and the conduct of the authorities will be subjected to Government investigation.

### THEORIES OF CHOLERA.

Now that the subsidence of the epidemic leaves time for reflection, we shall be able to direct attention to certain theories that have been advanced. That of Dr. Johnson has already been so ardently pushed that his opponents have as yet scarcely had fair play. We shall therefore be justified in placing before our readers the reply that has been penned by Dr. Chapman—one of the most able of those who disagree with Dr. Johnson.

Dr. Chapman's own ingenious theory will be duly noticed in the review which is in preparation of his work on cholera, from which we extract the following analysis of Dr. Johnson's views:—

This theory (of Dr. Parkes), after being considerably modified, has been adopted by Dr. George Johnson. He has taken from it an important element,\* the presence of which was likely to increase the probability of its truth in the eyes of rigorous scientific thinkers, has added to it a proposition† for which there is no ground in either experience or analogy, and has introduced it to the world supported on assumptions which he proclaims as truths. With a confidence alien to the genuine scientific spirit, he insists, in the absence of evidence, on the perfect adequacy of his doctrine to account for every phenomenon of cholera, and to dictate the only rational method of treating the disease, in a series of arguments, plausible at first sight, and calculated to mislead all who do not think for themselves, but which, when weighed in the balance of scientific experience and accurate reasoning, are found to be wholly "wanting."

Referring to the symptoms of choleraic collapse, Dr. Johnson asks, "What is the pathological explanation of this remarkable train of symptoms?" and then replies, "The one great central fact is this, that *during the state of collapse, the passage of blood through the lungs, from the right to the left side of the heart, is, in a greater or less degree, impeded.*" He afterwards says, "I believe the true explanation of the arrest of the blood in the lungs to be this:—*The blood contains a poison whose irritant action upon the muscular tissue is shown by the painful cramps which it occasions; the blood thus poisoned excites contraction of the muscular walls of the minute pulmonary arteries, the effect of which is to diminish, and in fatal cases, entirely to arrest, the flow of blood through the lungs.*"

Within so short a compass as the two foregoing paragraphs, it would be difficult, in my opinion, to find elsewhere so many and such important assumptions destitute of proof. It would be quite as reasonable to say that the powerfully contracted and empty, or nearly empty, condition of all the systemic arteries, excepting the large branches, or the distended condition of the systemic veins, their radicles and main trunks included, is the one great central fact of collapse. What is the central fact?—is precisely the question which has long needed, and is still needing, an answer; and Dr. Johnson's assertion that the impediment, in a greater or less degree, to the passage of blood through the lungs from the right to the left side of the heart is that central fact, is wholly unproven.

Again, he says—"The blood contains a poison." This assertion, though made by most of the authoritative writers on cholera, and repeated by almost every one who helps to swell the literature of the subject, is unsupported by any evidence of a satisfactory character; while, on the other hand, a large array of facts may be advanced in support of the hypothesis that the blood of cholera patients is poisoned in no respect whatever.

Again, Dr. Johnson says, "the irritant action" of this hypothetical poison "upon the muscular tissue is shown by the painful cramps which it occasions." Can he offer a single proof of the truth of this statement? Until he has done so, I reply confidently in the negative. In those diseases in which there

is unequivocal evidence of the presence of a poison in the blood—small-pox, scarlet fever, or measles, for example—the irritant action upon the muscular tissue is not shown by the painful cramps which it occasions, for it causes none. If, then, cramps do not occur in these signal instances of the presence of an organic poison, it is simply absurd to allege that the cramps of cholera are caused by a poison, the very existence of which remains to be proved. Moreover, cramps constantly occur in cases where there is the most unequivocal evidence that the blood is not poisoned. It has been indubitably proved that pure dynamic derangements of the blood supply of the nervous system, and especially of the spinal cord, are adequate causes of abnormal muscular contractions.

"The poisoned blood," Dr. Johnson says, "excites contraction of the muscular walls of the minute pulmonary arteries," but he tenders no proof whatsoever of this assertion, nor does he even supply reasons which render it seemingly probable. Having stated that the walls of the pulmonary arteries are muscular, and that under the influence of a stimulus they have the power of contracting upon their contents, he at once jumps to the conclusion that in cases of cholera they are irritated by a poison in the blood, and consequently, by contracting, impede the passage of blood through the lungs. He states that the injection of a concentrated solution of salt of soda, or a few grains of nitrate of silver, into the jugular vein, or the admission of air through a wounded vein in the neck or axilla, is speedily followed by death; and that beaten bullock's blood, mixed with air, requires nearly twice the pressure to drive it through the pulmonary vessels that suffices to drive unmixed blood through them. Having thus shown "that the movement of blood through the lungs may be quickly arrested by the addition of some foreign ingredient to the blood, and that this arrest is probably due to the power which the arteries possess to contract upon their contents,"\* he implies that in doing so he has adduced a proof that in cases of cholera the contraction of the pulmonary arteries is due to the exciting influence of a poison in the blood. I submit that there is here no connection between the premises and conclusion; and that, until the missing link is supplied, the very foundation of Dr. Johnson's hypothesis must be held to be a mere assumption. If the hypothetical poison be, as alleged, an efficient cause of the contraction of the pulmonary arteries, and of the cramps of the voluntary muscles, how comes it that Dr. Johnson does not teach that the systemic arteries are contracted by the same agency? If the blood be poisoned, surely its poisonous influence must pervade the whole body, and pre-eminently, according to his own statement, the muscular structures, and therefore the muscular coats of the systemic arteries. In restricting the action of the assumed poison as he has done, he has, it seems to me, weakened his own case; for that the systemic arteries are in a state of intense spasmodic contraction is believed by at least some competent observers. He says himself—"I suppose that no physiologist at the present day would deny that spasm of the arteries is as real a fact as spasm of the muscles." It is, therefore, difficult to understand how, in presence of this fact, of his hypothetical blood poison, and its assumed irritation of muscular fibre, he does not extend the influence of this poison to the systemic arteries.

Having stated his doctrine in the manner now described, Dr. Johnson says:—"We can now understand the sudden coming on of collapse, and its sudden passing off. Robust men falling down 'as if they had drunk the concentrated poison of the upas tree,' and recovering again almost as rapidly as 'patients who are resuscitated after suspension of animation from submersion in water.'" But such "patients" have not absorbed a poison, and it is not difficult, therefore, to understand their rapid resuscitation. If, however, cholera collapse be induced by a blood poison sufficiently virulent to irritate, and thus to produce contraction of the pulmonary arteries in the manner he alleges, it may be easy to understand "the sudden coming on of collapse," but it is almost, if not quite, impossible to understand "its sudden passing off." In those cases of disease in which we know an organic poison is present, its sudden passing off has never been observed; and as such a fact is contrary to all experience, its possibility is discredited.† Moreover, it is precisely in those cases in which the alleged contraction of the pulmonary arteries is especially intense, or, in other words, in which the spasmodic phenomena are markedly predominant,

\* Viz., the doctrine "that there is some impediment, or arrest of the circulation, in the capillary system generally."

† Viz., that the blood, which in cholera patients is alleged to be poisoned, "excites contractions of the muscular walls of the minute pulmonary arteries."

\* The reason given for "this arrest" is more than questionable.

† It may be alleged that the rapid recoveries from the poisonous effects of ether, chloroform, and hydrocyanic acid countermand Dr. Johnson's statement; but it must be recollected that these are not organic poisons.

and in which the eliminative processes, vomiting and purging—regarded by Dr. Johnson as Nature's method of getting rid of the poison—have been least active and continuous, that recoveries, when they do occur, are most rapid.

"The most interesting and conclusive evidence," says Dr. Johnson, "that arrest of blood in the lungs is the true key to the pathology of choleraic collapse, is to be found in the simple yet complete explanation which it affords of all the most striking chemical phenomena of the disease—the imperfect aeration of the blood, the fall of temperature, the dark and thick appearance of the blood, and the suppression of bile and urine." Now, this arrest of blood, considered as the central fact of collapse, is nothing more nor less than suffocation, or asphyxia; but, in asphyxia, the characteristic phenomena of choleraic collapse are never induced; the features are not shrunken, but tumid; and the body generally, though more or less livid, is in no respect shrunken, as it is in the algide cholera. The differences, in fact, between the two states are numerous and essential. In asphyxia, the liver and kidneys are gorged with blood, but in choleraic collapse they are both anæmic. Without comparing the two conditions in detail, I will merely state a few conclusive facts. First, whereas in cholera "a mortal coldness" comes over the body with astonishing rapidity—sometimes in a few minutes—in asphyxia there is no such rapid diminution of heat—the long continuance of the animal temperature, even after the heart has ceased to beat, is a characteristic fact. Second, whereas in cholera cadaveric rigidity comes on with extreme rapidity, in asphyxia it continues absent "almost always for a much longer period than from death under other circumstances, and from other proximate causes."\* Third, whereas in choleraic collapse there is suppression of bile and urine, in asphyxia there is neither one nor the other. Thus it appears, that of the several phenomena stated by Dr. Johnson, in the passage last quoted, as being explained by his doctrine, only one—viz., the imperfect aeration of the blood—is really accounted for; and when this occurs in cases of pneumonia so severe as to cause the blood in the systemic arteries to become dark, no symptoms like to those characteristic of choleraic collapse are observable.

Dr. Johnson says—"Suppression of bile and urine during the stage of collapse is a necessary consequence of a limited supply of oxygen, which results from obstruction in the lungs." If so, why is there not a like suppression in asphyxia, and severe cases of pneumonia? If the blood in choleraic collapse contains a supply of oxygen so limited as to preclude the possibility of any oxydation whatever, in either the liver or the kidneys, and thus to arrest entirely the functions of those organs, how is it that there is nevertheless sufficient oxygen in the blood to enable the cerebral functions, which involve a considerable amount of oxydation, to continue without interruption? How is it that when collapse is most profound, and when death is approaching, there is still sufficient oxygen in the blood to permit of a recommencement of oxydation, resulting in a notable increase of animal heat, so that the temperature of parts of the body rises before death, and that of the whole body after death, the elevated temperature being prolonged for a considerable time?

Dr. Johnson accounts for the admitted fact, that in some cases of choleraic collapse "the secretion of milk continues apparently diminished," by saying—"The chief constituents of milk, casein, sugar, oil, and water may be obtained from the blood without the addition of oxygen. The secretion of milk, therefore, continues during the stage of collapse." What I have already said, concerning "the defective supply of oxygen" as the alleged cause of the suppression of bile and urine, renders Dr. Johnson's ingenious explanation of the continued secretion of milk extremely questionable, and will be probably considered as completely confuting it.

While the positive side of Dr. Johnson's theory is so demonstrably erroneous, the negative side is not less remarkable by the number of phenomena characteristic of cholera which it fails to explain. Of the prodromata of cholera—slight headache, slight deafness, singing in the ears, dizziness, faintness or syncope, and the copious discharge of pale urine—he renders no account, and makes not the least attempt to show how they are produced. His great discovery that vomiting and purging are "the salutary efforts of Nature, by which the morbid poison is eliminated," is not sufficient; if his doctrine be true, it should surely explain the "modus operandi" of these important processes. The fact of the contraction of the bladder

to the size of a walnut he passes quite unheeded. The seemingly paradoxical fact, that while the systemic arteries are almost wholly emptied of blood during collapse, sweat is freely, and very often profusely, secreted, also passes unnoticed as well as unexplained. The remarkable calmness and clearness of the intellect during collapse—notwithstanding the suffusion of the brain with blood, the supposed poison of which is said to cause the pulmonary arteries to contract so vehemently as to impede or arrest the circulation, and thus to cause death—receive neither comment nor explanation. The rise of the temperature of the body immediately before death, and for some time afterwards, and the astonishing muscular contractions, often involving movements of the limbs, sometimes even of a seemingly co-ordinated character, after death, obtain no recognition whatever.

If it be admitted that a poison exists in the blood, and that it effects the contraction of the pulmonary arteries in the manner stated by Dr. Johnson, his hypothesis does not account for the contraction of the bronchial tubes and the consequent absence of air in the lungs, which is denoted by the extreme collapse observable in these organs. So extreme is this collapse, that, as stated by Dr. Parkes, "several observers have opened bodies under water, believing that air must have been generated in the pleural cavities; but this was found not to be the case, and the shrinking of the lungs must depend on some cause existent in itself." This very interesting and remarkable fact, wholly inexplicable, I apprehend, by Dr. Johnson's theory, is passed over by him in silence. Dr. Parkes feels the difficulty and expresses it.

There is yet another difficulty connected with the lungs: some time before death, usually two or three hours, there is often, as already stated, "some return of heat in the scalp and forehead, over the region of the heart or whole chest, and it may be also over the abdomen; the extremities are still icy-cold, and the cholera visage is unaltered." Now it is fairly presumable that when the supposed poison in the blood is on the point of destroying its victim, it must, according to Dr. Johnson's hypothesis, exert its maximum of poisonous energy on the muscular coat of the pulmonary arteries; and yet at this very time it appears that the poisonous blood often courses through the lungs again, and produces, in consequence, a considerable elevation of temperature. Dr. Johnson fails to explain this very curious and interesting fact, seemingly adverse to his doctrine.

The kidneys are in a very pre-eminent degree the organs by which poisonous elements in the blood are separated from it, and thus cast out from the body: if vomiting and purging be "the salutary and curative efforts of Nature" by which the cholera poison is eliminated, the fact that Nature does not avail herself of the chief eliminating organs—the kidneys—in order to effect a more rapid and complete expulsion of the poison from the system, is certainly very astonishing and inexplicable; but Dr. Johnson ignores this fact also, or, at least, makes no attempt to reconcile it with his doctrine of elimination.

Tried by the test of practice, Dr. Johnson's theory is found to be no less unsatisfactory than it has been proved to be by the evidence given above. He says: "I maintain that this pathology is a compass which will guide the intelligent practitioner over a 'sea of troubles' and perplexities in the treatment of cholera." Guided by this compass, Dr. Johnson has discovered that "the natural method of cure is eliminative," and that the best eliminative method consists in the administration of castor-oil. In section 13 of the next chapter will be found a considerable body of evidence, proving that the practice of giving purgatives to cholera patients is an extremely dangerous one, liable, in fact, to induce collapse and destroy life; and in the same section, the reasons of their dangerousness are explained. The experience and reasons there given are remarkably accordant with the conclusions expressed in the report on the results of different methods of treatment pursued in epidemic cholera, addressed to the President of the General Board of Health, by the Treatment Committee of the Medical Council of the Royal College of Physicians. The results of the several plans were tabulated, so as to show the *per centage* of deaths following each plan. That following the use of eliminants was the greatest of all, viz. 71.7; the per centage of deaths following the treatment by castor-oil was even greater than that which followed the use of eliminants in general; it was 77.6 *per cent*. In the report on the treatment of cholera drawn up for the Royal College of Physicians by Dr. Gull, he says—"The popular theory that the discharges are an effort of nature to throw off a *materies morbi* is not only unsupported

\* Copland's "Dictionary of Practical Medicine." 1866. ART. Asphyxy.

by any known facts of the disease, but when applied to practice is found to increase the violence of the symptoms." "We have only to say," observes the *Lancet*, of June 2, 1866, "that there is a discrepancy between Dr. Johnson's experience, and that of the profession. His treatment was largely tried in 1854, and generally and strongly disapproved." Considering these decisive statements, the reader will scarcely be surprised by the following confession, published in 1866 by Dr. Johnson himself: "I have not the faintest hope or expectation that a specific remedy for such a disease as cholera will ever be discovered."\*

## Notes on Current Topics.

**CASUALS IN CLERKENWELL.**—We have extracted from the *Times* the recent revelations respecting the manner in which casuals have been turned away from the Clerkenwell Workhouse. It is but fair to report that one of the guardians has ventured on a reply. In his letter this philanthropic gentleman asserts that "it is no great marvel that the porter should behave in a rude manner to him (Mr. While, who brought the matter to the notice of the public), and order him off the premises, and tell him he was drunk," and this because Mr. While knocked so loudly at the door. Never, we assert, was a more indecent apology put forward, and we only regret that Mr. Hopkins, the guardian who pens it, cannot be compelled to occupy, for at least one cold night, the position of the two unfortunate casuals whose rights were so justly taken up by Mr. While. But, lest we should be thought partial, we reprint below Mr. Hopkins' letter to the *Times* :—

SIR,—As reported by you in the *Times*, an inquiry was held by Mr. Corbett, the Poor-law Inspector, into the charges brought against the officials of the Clerkenwell Casual Wards. I, as one of the guardians, attended that inquiry, and I am bound to say that so far as the case then investigated is concerned, I consider our official did his duty in refusing to admit the two men whose cases were brought under the notice of you and the Poor-law Board. The evidence of the porter on oath, which was unshaken by the severe cross-examination of Mr. While, or the Inspector's utmost scrutiny, was that the two applicants were drunk. That evidence was corroborated on oath by Police-constable 158 G, an intelligent officer, who gave his evidence very fairly. Mr. While, on the other hand, swore they were sober, and called a witness to prove, as I understood, that he was sober. My impression, as an impartial witness anxious for justice, is that Mr. While was so excited that he was not a competent judge as to the condition of the two casuals. I gather this from the fact that the policeman swore that he heard a violent knocking when he was in Pear-tree-court, some 130 yards distant, and on his hastening to learn the cause, he found it was Mr. While demanding admission for these men at the casual ward, and the same policeman swore that such was his excitement that, "until he turned his bull's eye full upon his face, he thought he was drunk too," it is no great marvel that the porter should behave in a rude manner to him and order him off the premises and tell him he was drunk, when the noise could be heard so far off. I cannot resist the thought that Mr. While's sympathy for the two casuals was more than counterbalanced by his utter regardlessness of the slumbers of a large number of poor wayfarers who were sleeping in the wards.

Allow me to ask you, sir, and your readers, if Mr. While would not have acted in a fairer manner to the Clerkenwell Guardian Board, if, instead of rushing into print and writing to the Poor-law Board, he had made his complaint to us first, either personally or by letter, and then if we had taken no notice of his complaint, or instituted no inquiry into the matter, to have had recourse to the extreme measures he has? As it is, none of us were aware of either of the cases until we read them in the *Times*, and we are thus brought prominently before the public for the alleged infraction of laws which it is our hearty desire and anxious wish to have carried out.

\* Notes on Cholera, p. 87.

In conclusion, allow me to say your reporter is altogether in error when he says that the guardians had resolved that no one should be admitted to the wards unless introduced by a guardian. The guardians, I beg to say, have nothing to do with the admissions; their instructions to the casual wards officials being to admit all wayfarers, homeless and destitute.—Yours obediently,  
JOHN W. HOPKINS, Guardian.

**ROYAL COMMISSION ON WATER SUPPLY.**—We are happy to find that the question of water supply is to receive further investigation. A Royal Commission has been appointed to inquire into the means of obtaining pure water for London, and the chief towns. Sincerely do we hope that inquiry may result in action. Too often a commission has only been a mode of respectably shelving a difficult question. Let us hope that in this instance the Government is in earnest. Nothing is of greater importance to the people than an abundant supply of pure water, and nothing ought to interfere with the inquiry, or prevent the decisions that may be arrived at being turned to account.

## Proceedings of Societies.

### MEETING OF THE HARVEIAN SOCIETY.

DECEMBER 20, 1866.

President—Dr. TYLER SMITH.

#### CASE OF INHERITED SYPHILIS.

DR. DRYSDALE showed a patient, a young woman, aged 19, with the usual characteristic marks, described by Mr. Hutchinson, of inherited specific disease. The girl had pegged teeth, remains of interstitial corneitis, and was quite deaf. She had been blind at the age of seven, and had been deaf since the age of twelve. Neither the father nor mother would admit that they had been infected. Dr. D. said that he had at that time four similar cases under observation, in all of whom the appearances of the teeth, &c., were associated with the history of inherited syphilis. He considered that Mr. Hutchinson had made very great addition to the knowledge of the causation of degenerative diseases by showing that what but a few years ago would have been looked upon merely as scrofula, was in reality a consequence of syphilitic poison in peculiar circumstances.

#### ON THE NATURAL HISTORY OF SYPHILIS.

DR. DRYSDALE, in treating of this subject, explained that he wished to make a few remarks upon the lesions which he had found, in his own experience, to arise when the disturbing influence of mercury was withdrawn. Comparative statistics having convinced him, as it had done others, of the injurious effects of a long course of this drug in syphilis, he had abandoned it, and he wished to ascertain, as far as his materials served, what was the natural course of the disease. His experience led him completely to endorse the opinions as to the nature of the disease entertained by Hutchinson, Cooke, &c., and to class it with the exanthemata; and he would endeavour to present the points of analogy as follows:—Firstly, as regarded incubation. In scarlatina the incubation varied from a few days up to three weeks; for typhus fever, from days to weeks; for inoculated variola from four to eighteen days. This was imitated by the primary lesion in syphilis, which had an incubation period varying from a few days up to two months; the soft sore, on the other hand, had no incubation. To prove this assertion he cited some cases, as—Case 1. A young woman, aged 19, had indurated sore on lower lip, followed by rosolia and sore throat. Seen 10th March, 1865. Had observed the sore first on the 1st of March. Her friend, to whom she was engaged, had bitten her lip in play about the beginning of February, 1865. Incubation, three weeks. Case 2. E. K., 42, during his wife's confinement, July, 1865, went with a strange woman once, at the beginning of the month. Indurated sore appeared in September. Pustular syphilis in October. Two months of incubation. On the other hand, he had notes of cases where there seemed to be scarcely any incubation period. The next point of analogy between syphilis and the exanthemata lay in the period which elapsed before the appearance of

the eruption. His experience corroborated that of most writers in making this interval about six or seven weeks. This was, of course, longer than what was seen in variola, but in some cases of malignant syphilis this interval was much shorter. The eruptive period of syphilis constituted in many healthy persons almost all that had to be said about the disease. The eruptions in such cases assumed the forms of roseola, lichen, and psoriasis, and had a tendency to fade away and reappear for periods varying from weeks up to months, and, in rare cases, to years. During the whole of the eruptive period the disease was contagious; as Vigo said long ago, "Notum est quod morbus gallicus contagiosus est; tamen contagio ista non extenditur nisi in principio morbi." Dr. Drysdale said he confidently believed that during this eruptive period the internal parts were scarcely ever attacked, except in infants. In healthy adults, these eruptions when not interfered with except by good diet and attention to hygiene, &c., gradually died away, leaving the patients for the most part completely free from any recurrence of the disease. He had seen numerous examples of this fact. On the other hand, when patients were of scrofulous constitution, delicate in health, drinkers, or worn out by fatigue, poverty, or bad living, or still more by the debilitating effects of mercurial courses, the eruption was not the end of the disease, and was itself often of a formidable character. Rupia with large blebs might be the very first symptoms observed, with great prostration of strength, and even in rare cases death. Such cases were fortunately rarer now than formerly. Rupia might, in his experience, occur from weakness of constitution and bad hygienic causes alone. Old age or extreme youth were unfavourable in the prognosis of syphilis. Women in general, he thought, suffered more than men in proportion to the very small number of them infected, as compared with men. Alopecia occurred in about sixteen out of twenty cases of natural history of syphilis in his experience. Crusts in the hair about as frequently. Roseola was by far the most frequent form of skin eruption, then papules, then squames, then pustules. He had seen one case of syphilitic orchitis among those treated, eighteen months after infection. Iritis had occurred twice in fifty cases of natural history. Serpiginous sores, especially of the lower limbs, were not uncommon, and came on after the eruptions faded. Mucous tubercles and sore throat were extremely common in the natural history of syphilis. Periostitis was not common in the eruptive period. Tertiary syphilis was only a rare event in the natural history of the disease. In his experience the lesions of this stage most frequently seen were corneitis, serpiginous ulcers, emaciation, and affections of the fauces, nostrils, and larynx. He had not often seen deafness to arise in adults, although in the cases of inherited syphilis seen at hospitals, deafness was seen in one-tenth. He had seen a case of acetic with albuminuria, lately, when he had some idea that there existed syphilitic inflammatory deposits in the liver. Epilepsy had occurred in one case of natural history he was well acquainted with, and he had often seen it when he could hear no account of such specific treatment having been used. He had seen syphilitic patients dying of phthisis, but had not as yet ventured to look upon syphilis as more than one of the causes of the fatal result. He had also seen many cases of nervous diseases and local and general paralysis in persons who apparently had suffered from syphilis, and had not been much mercurialized; but this was one of the most difficult points to clear up, since it was one of the admitted properties of mercury to cause paralysis, as seen in a large scale at the mines of Idria and Almaden. As to the transmission of the disease to the offspring, his experience led him to say that if the father was affected by the eruptions when he impregnated the woman, the mother and child would be affected, and the latter would either be prematurely born, or soon have eruptions; but after a few years the man lost the power of engendering syphilitic children, although his children might be ricketty. If the mother were alone infected, he had found that the offspring were likely to be affected for several years; but that the later born became healthy. When the woman was infected during pregnancy, she rarely infected the child. Case 3. A lady, seen June 2nd, 1866, with sore throat, complete alopecia, and mucous tubercles, brought with her an infant fourteen days old, which was and had remained uninfected. The mother was infected two months before confinement. Children were very rarely, he thought, infected at birth, but he had seen several cases of infection shortly after birth. He had seen one case of syphilis communicated by vaccination, where both parents were healthy. Summing up the results of his experiences, he would say that all the lesion which we were accustomed to see among mercurially

treated patients might also be seen in the natural history of the disease when no mercury was used, but that the severer forms occurred very much more rarely, and at a far later period, when the drug was dispensed with, that such cases were much more easily restored to health. Again, the natural history of the disease showed children infected for some years, and then healthy ones appearing, whilst in mercurial cases abortions and infected children might in his experience go on indefinitely. With regard to the prognosis of inherited syphilis, he had found it to be very grave, if the eruption appeared soon after birth; but if the eruption did not appear until two months or more after birth, the prognosis in general was favourable, if simple means were used. As to cases of inherited syphilis in after life, he could not say much about them as yet, since the oldest patient he had thus treated was only five years old; but that child, a boy, was in good health, and could not be detected as one of the cases of inherited syphilis described by Hutchinson. He was inclined to think that the prognosis of the disease was far graver in childhood than in adult life. In conclusion, Dr. Drysdale said that it was deplorable that there were so few observations given forth of natural histories of syphilis. With the exception of Boeck, Baerensprung, Diday, &c., he could scarcely enumerate any number of authors who had given numerous histories of this kind, whilst M. Ricord and his pupils' habit of giving six months daily doses of mercury had so completely, either for good or for ill, obscured the disease, that it would require at least twenty years before much could be said about the natural history of syphilis. Mr. Allingham and Mr. Dunn had done much for the natural history of infantile cases.

Mr. DE MERIC observed that the author's paper was able, but very much wanting in method. It was called an essay on the "natural history of syphilis," but it was in reality a philippic against the use of mercury. As the author did not employ mercury, any cases he might have given would have been very valuable. However, as he had followed the plan he had done, he (Mr. De Meric) would make some remarks on one or two points in the paper. Firstly, he did not by any means admit the cogency of the analogy drawn between syphilis and variola. It was true that there was some similarity, but there was immense dissimilarity also between syphilis and the exanthemata. The very length of incubation referred to by the author, and of which he had lately had an example when the period was so long as two months, was against the analogy. Then again, the relapses which were so common in syphilis were unknown in variola, &c. In small-pox we saw a hurricane at first, and then all was over; but this was by no means the case in syphilis. Next, the author had launched into the question of visceral syphilis, and also into that of inherited syphilis, although neither of them had anything to do with the natural history of the disease, and then he had concluded with mentioning the treatment of the disease. Now, with regard to this he must say that when we saw a patient with indurated sore, he thought we had no right to withhold mercury; twenty years of practice with mercury, with few evil results ensuing, and much good, had convinced him how necessary it was. Nevertheless, such discussions did good by forcing persons who gave mercury to look well into the matter, and as they were always conducted by the author in a most polite and courteous manner, they were very agreeable.

Mr. BERKELEY HILL said that it was unprofitable to touch on more than one or two of the numerous points raised in the author's papers. With regard to the question of comparative treatment of the disease, as recorded by Boeck and Bidenkap in Christiana Hospital, it was asserted by Dr. Boeck that the number of relapses when he cured syphilization was only ten per cent., whilst when derivation was used it was 23, and when mercury was used it was 33 per cent.; but it must be observed that the patients who were syphilized were kept in hospital so long that they got through all their relapses before they went out, whereas when derivation or the blister plan was used in 140 cases, the patients went out, had a relapse in a week or two, and then came back.

Mr. CURGENVEN said that he had seen several cases of natural history of syphilis, of which the following were examples:—A tailor, with urethral chancre, had sore throat and eruptions, and took no treatment. His first child died; his second also and his wife were infected. He then placed both under bichloride of mercury; they both got well, and had a child, which recovered from eruptions under mercury. In the case of another patient, a soldier, treated without any specific, seven years afterwards on the eve of marriage sores broke out again like the old sore.

Mr. BENSON BAKER said he took much personal interest in this question. Some months ago he pricked his thumb, when making a post-mortem examination, and having soon after to perform circumcision, he was infected; in a day or two his thumb was indurated, he had large glands in the axilla of same side, and in six weeks afterwards he had eruptions of roseola; not wishing to take mercury he went to the sea-side, and the eruptions disappeared; but on returning to London they broke out afresh, when, on the advice of Mr. Gascoyne, he took mercury, and he was now without any eruption. He had often heard from veterinary surgeons that they had seen gonorrhœa and sores on the penis in dogs, and thought that this would be a very curious matter for investigation.

Mr. HENRY LEE said that Dr. Boeck's point was that the indurated sore, when frequently inoculated on syphilitic persons, could be re-inoculated again and again in a series. The learned professor had come over here a year ago, and yet, up to this time, not a single case of verification of his results had been obtained. Now, although we might see it some time or other, life was short, and he would like to see the thing done before he died. It must be remembered that, in the Lock Hospital, no care was taken to cover up the sores of those practised upon; hence there were many ways in which the matter from soft sores might be conveyed, and this became a means of infecting other patients. As to the natural history of syphilis, he continually saw bad results where the disease was left to its own course. A medical man, a friend of his, has some after symptoms, and upon his being asked by Mr. Lee whether he did not regret not having taken mercury at the commencement, he replied, "Certainly, I do very much repent it." With regard to visceral syphilis, however, he was inclined to think that the use of mercury, internally, might give rise to such symptoms. This result he avoided by only administering the metal in the form of calomel vapour bath.

The PRESIDENT said that his experience of syphilis was mainly in cases of pregnancy and infected children. A man he had often seen might marry without any sign of syphilis about him, and to all appearance in perfect health, and yet his wife might have syphilitic abortions her whole life. He had known a case like this, where the husband was so affected that he committed suicide. This occurred in a wealthy gentleman in whom the mercurial treatment had been tried. Again, he had often seen a man syphilitic, and his children all syphilitic, and the mother remain uninfected. In some women the disease seemed to pass through them without doing much damage to their constitution. He remembered when the first non-mercurial treatment of syphilis appeared. He saw a death from rupia under this treatment. For infants, the best treatment, he thought, was the flannel band with unguent hydrarg.

Mr. SEDGWICK mentioned the case of a tailor, in whom there was no trace of syphilis to be seen; his first three children, however, died of the disease. The fourth is now strong and healthy. He thought that as a rule we could not regard the paternal influence as nearly so strong in the production of syphilis as the maternal.

Dr. MEREDYTH gave the case of a patient whom he had treated by the expectant method for roseola and erosion, and had treated the alopecia and headache by means of iron. No new appearances had been seen in this case. Three years after this he had delivered this gentleman's wife of a healthy infant, and this child, now two years and a half old, was in good health. On the other hand, he had seen lately a case of necrosis of the frontal bone in a patient, who never had taken mercury. As to syphilization, he had tried inoculations of indurated sores on persons with syphilis, day after day, for six weeks, and had never obtained any result.

Dr. DRYSDALE thanked Mr. De Meric for his strictures on his method, and should try another time to avoid the word mercury. He wished, however, to remark that Dr. Diday in his "Natural History of Syphilis," had found it necessary to speak of the mercurial treatment all through the book. No one treated scarlatina, or measles, or variola now by attempting to cure these diseases. They only did then but to keep the patient up whilst the disease was being eliminated, and this they ought to do when the eruptions were eliminating the syphilitic veins. If Mr. De Meric and Mr. Lee would lay their hands on their hearts and say that they were well acquainted with the natural evolution of the disease, and that they preferred to alter this evolution by attempting to cure the disease by mercury, he would say no more; but he knew very well that these gentlemen were not well acquainted with the natural history of the disease, since wherever they saw it they gave the so-called specific. With regard to Mr. Cuvengen's

cases, they were interesting, and he hoped he would give some more like these. Mr. Benson Baker's own case was most instructive; 1st, there was no incubation of the sore; 2nd, there were six weeks' incubation of the eruption; 3rd, the eruption faded by change of air; and 4th, as usual, again appeared. This quite accorded with his own experience, and had he been in Mr. Baker's place he would have been quite prepared for it. With regard to Mr. Lee's vapour bath treatment, he saw nothing against it. He continually advised simple vapour baths in roseola, and as calomel was insoluble it could do no great harm, as it did not, he believed, ever enter the system, unless the patient inhaled the vapour, which might of course salivate him. But this appeared not often to occur. Upon the whole, he thought that Mr. Lee might very fairly be considered as a follower of the natural history treatment of the disease, since he encouraged the skin to throw off the virus by means of the vapour bath. There was no doubt that using calomel along with it made many persons attach a superior efficacy to the bath, and that it was one way of treating them rationally without alarming their prejudices. He concluded by thanking Dr. Meredyth for his contribution of such an interesting case to the natural history of the disease. Lastly, with regard to syphilization, he believed that were it not for the unpleasantness of the process and the trouble it gave to the medical attendant, there was more in it than was dreamt of in our philosophy; and as he had found Dr. Boeck more learned upon the subject of syphilis than any other authority he was acquainted with, he hoped sincerely that syphilization might yet be found to prove of service in difficult cases, although the inoculation of hard sores on syphilitic persons required to be further experimented upon by persons of unbiased judgment like Mr. Lee.

#### OBSTETRICAL SOCIETY OF DUBLIN.

Dr. ATHILL detailed the particulars of a case of

##### INTRA-UTERINE POLYPUS.

The patient was an unmarried woman, aged 45. She was in an extremely weak and emaciated condition, being rendered almost exsanguine by the repeated and latterly continuous attacks of uterine hæmorrhage. On vaginal examination the uterus was found to be greatly enlarged, perfectly globular, the cervix being entirely obliterated, and the os closed, so much so as to admit with difficulty the point of a uterine sound. A small sponge tent was carefully introduced into the os, which dilated it in a few hours to the size of a sixpence. On its removal this was at once replaced by a larger one, and finally by one of even greater size. These acting very satisfactorily opened the os to the size of a crown-piece. Dr. Marion Sims' intra-uterine ecraseur was then introduced, but all attempts to snare the polypus with it failed. An ordinary wire ecraseur was then tried with no better success, the extreme narrowness of the vagina, and the unyielding nature of the uterine walls adding greatly to the difficulty of the operation. Recourse was then had to Gouche's canula, with which, after some difficulty, a ligature of double whip-cord was carried round the pedicle and tightened. Some vomiting followed. The ligature was tightened morning and evening by means of a winch, ingeniously adapted on the plan suggested by Dr. Beatty, to the end of the connecting rod of the canula.

Five days elapsed before the ligature cut through the pedicle, and even then the polypus was retained in utero, and had to be removed by means of a small pair of forceps. The polypus, which was fibrous, was the size of a large egg. This woman had more than one well-marked rigor, and much uneasiness was felt lest she should be attacked with pyæmia. In order to obviate the risk which the slow action of the ligature entails, Dr. Athill devised and exhibited to the meeting an instrument which may be briefly described as an adaptation of the canula of Gouche to the ecraseur, the end of the ecraseur being modified so as to allow the canula, by which a wire rope is carried round the pedicle of an intra-uterine polypus, to pass through it, the rope being then attached to the ecraseur. The operation is completed as by an ordinary wire ecraseur, thus uniting the rapid action of the ecraseur to the facility of application afforded by the canula of Gouche.

#### THE HEALTH OF LONDON.

(From the Weekly Return of the Registrar-General.)

In the week that ended on Saturday, December 29th, the births registered in London and twelve other large towns of

the United Kingdom were 3998; the deaths registered 3071. The annual rate of mortality was 26 per 1000 persons living.

In London, the births of 990 boys and 910 girls, in all 1900 children, were registered in the week. In the corresponding weeks of ten years 1856-65, the average number, corrected for increase of population, was 1871.

The deaths registered in London during the week were 1436. It was the fifty-second week of the year; and the average number of deaths for that week is, with a correction for increase of population, 1554. The deaths in the present return are less than the estimated number by 118.

The daughter of a pen merchant, aged 16 years, died on 23rd December, at 3, Boar's-head-yard, Whitechapel, of Asiatica cholera (14 hours).

Fourteen deaths from diarrhoea were registered during the week.

Small-pox proved fatal to 27 children and 8 adults; it was not stated in the returns that in any case the patient had been vaccinated. In the sub-district of Christchurch, Marylebone, 5 deaths from small-pox were registered. The registrar of the sub-district of St. Giles South, remarks that "small-pox is very prevalent and great inconvenience is felt from the want of proper accommodation for patients suffering from the disease."

Twenty-five deaths from measles, 41 from scarlatina, 10 from diphtheria, 58 from whooping-cough, and 41 from typhus were registered during the week.

The influence of the temperature on the mortality from diseases of the respiratory organs is very great. In the week which ended October 13th, the mean temperature of the air was 52.4 degrees, and the deaths from bronchitis were 89; as the air became colder, the deaths from bronchitis increased; last week the mean temperature was 44.0 degrees, and the deaths registered from bronchitis were 224.

Eight deaths from burns or scalds were registered in the week. One of the unfortunate victims was a domestic servant, whose clothes took fire when distended by crinoline.

A child, aged one year, died on 21st December in consequence of swallowing mistletoe berries.

The annual rate of mortality last week was 24 per 1000 in London, 28 in Edinburgh, and 24 in Dublin; 25 in Bristol, 26 in Birmingham, 33 in Liverpool, 30 in Manchester, 25 in Salford, 28 in Sheffield, 27 in Leeds, 23 in Hull, 37 in Newcastle-upon-Tyne, and 27 in Glasgow.

The high rate of mortality which has prevailed during the past thirteen weeks in Newcastle-upon-Tyne has been caused by an unusually fatal epidemic of scarlatina, from which 220 deaths have resulted in the past seven weeks out of a total of 601 deaths.

## METEOROLOGY OF 1866.

By R. H. ALLNATT, Esq.

THE past year has been fertile of meteorological phenomena, and was marked by great insalubrity, and in some of the summer months the death-rate exceeded the estimated average by nearly a thousand. To what influences are to be attributed the pathological conditions which prevailed, and how far may they be due to the specific action of atmospheric combinations? The issues are of vital importance, and can only be approached by patient deduction from physical facts. It may be mentioned, "in limine," as an extraordinary, and, according to our present notions, most anomalous occurrence, that during the height of the late epidemics—the cholera and cattle plague—ozone manifested an almost unbroken series of maximum development, and on the cessation of those diseases the monthly average gradually diminished to a point two-thirds at least below that of its full registration. Deep purple mists, which spread at various periods over the landscape, gave evidence of the antagonistic action of atmospheric and telluric electricity.

### JANUARY.

The new year was ushered in by a wild tempestuous wind and driving rainfall. The month was remarkable for its high atmospheric temperature. On the 12th, amid showers of sleet and snow, the thermometer sank 12 deg. below freezing, and in a few hours rose to 46 deg., and during the remainder of the month once only fell so low as 35 deg. On the night and morning of the 22nd the respective barometric readings were 47 deg. and 50 deg. Fahrenheit. A terrific hurricane raged on the 3rd, and minor gales on the 7th and 8th. There were

alternate periods of ozone and antozone. Rainfall occurred on 16 days, and amounted to 4.62 in., which is considerably above the recognized average of the month. There were three cloudless days, and the predominant wind was tropical, W. or S.W.

### FEBRUARY.

On the 11th an equatorial cyclone raged, accompanied by frequent flashes of lightning from S.W. At Frant, Sussex, which, as the crow flies, is about 25 miles from the sea, the gale committed great havoc, the pressure being somewhat about 40 lb. to the square foot. Houses were partially unroofed, and at Eridge-park, one of the seats of the Earl of Abergavenny, 3000 trees were uprooted by the fury of the blast. Spray from the sea was borne nearly 30 miles. Intermittent tropical gales occurred also on five other days, and were preceded or followed by auroræ boreales, streams of electric cirrus, lightning, and solar haloes. Diurnal oscillations of the barometer were considerable, and ranged from 29.40 in. to 30.30 in. Rainfall extended over 15 days to the extent of 5.33 in.—upwards of 3 in. above the mean. The prevailing cloud, which almost daily obscured the sky, was the composite or rain cloud, fully developed. Three days alone were cloudless.

### MARCH.

The passing of large solar spots gave rise to high magnetic action, and consequent atmospheric perturbations. The prevailing winds were keen and bitter from N. and E., and the whole month was abnormally unhealthy. During the first three weeks the registered rate of mortality was upwards of 500 above the average. There was not one cloudless day; tropical and polar winds were almost equally balanced; rain fell on 19 days, and amounted to 1.90 in., which is below the acknowledged mean of the month by about the eighteenth of an inch.

### APRIL.

Three consecutive days were cloudless, when the sun shone with full vigour, and a cold and detrimental E.N.E. wind prevailed. Barometric readings were high, and ranged from 29.00 in. to 30.00 in. The wind in combination touched the N. and E. on 15 days, and on the remainder it was complicated with S. and W., so that the balance was nearly equalized. The mean temperature of the month was considerably lower than that of last year; the range by day was from 40 deg. to 62 deg., and by night from 34 deg. to 55 deg. On the 26th, at 2 P.M., the thermometer in full sun rose to 111 deg.; in shade, N. aspect, it stood at 70 deg. On the 29th it had fallen full 30 deg. Rain fell on 19 days, and amounted to 2.41 in.; from the 2nd to the 4th, inclusive, it was mingled with snow and sleet. From the 1st to the 30th, *de die in diem*, the ozonoscopes registered 10 deg., or the maximum of ozone.

### MAY.

The weather of this month was marked by extreme unhealthiness. Towards the latter portion the wind became established [in the N.E., and sometimes blew with the fitful violence of a gale; hoar-frost frequently covered the ground, and vegetation was greatly retarded. The mean temperature was little above 51 deg., which is 8 deg. lower than that of last year. The variation was from 40 deg. to 61 deg., thus making the range of morning temperature 21 deg. Hail fell on the 3rd and 4th, and rain on ten days, amounting in the aggregate to 1.0 in., which is considerably less than the acknowledged monthly mean. Cloud predominated on 21 days; the modification was that of the composite or thunder-cloud, either fully formed, or the elements existed isolated in their respective wind currents. The diurnal oscillations of the barometer were limited, and the entire range was below an inch. As in last month, so in this, ozone manifested a consecutive daily maximum, and notwithstanding the full development of this allotropic condition of atmosphere, the rate of mortality was excessively high, and diseases raged, which are supposed to be specially controlled by its sanitary influence. The hygrometric state of the air was very low, amounting sometimes to 50 per cent. only of moisture; telluric evaporation was consequently rapid, but was speedily carried off by the stirring winds that prevailed.

### JUNE.

We have the recorded rate of mortality again this month unusually high, the aggregate, corrected for increase of population, having amounted to little short of 1000 beyond the estimated average. The rainfall, though not excessive, was some-

what above the mean, and was spread over 14 days. The temperature represented less, certainly, than the average of past years; but, nevertheless, it maintained a considerable elevation. There was during the month but one purely cloudless day, and thunder clouds, or their elements in antagonistic currents, existed perpetually. The winds at the commencement and for nearly three consecutive weeks were tropical concomitants of thunderstorms, and were generally paroxysmal or squally. Atmospheric pressure underwent but slight variations, and the diurnal oscillations were comparatively inconsiderable. The range of the thermometer was 20 deg. The highest night temperature 63 deg., and the lowest 47 deg. The maximum reading occurred on the 28th under the influence of a N.E. wind, and the lowest on the 6th, beneath a tropical and gusty S.W. wind. Ozone was very largely developed, the maximum, or 10 deg., having been reached on 24 days. The hygrometer registered a fair balance of atmospheric humidity, varying from 15 to 50 per cent.

## JULY.

The whole of this month was also marked by great unhealthiness, and the temperature manifested strange fluctuations. During the first week the morning register ranged from 56 deg., to 60 deg.; and the night from 40 deg. to 56 deg., and rainfall occurred every day. On the 9th the weather became dry and sultry, and on the following day the thermometer rose to 71 deg., at a later hour to 80 deg., and in the sun to 114 deg., marking a difference within a brief period of temperature amounting to some 35 deg. The predominant cloud modification was the composite, or raincloud, which occurred on 22 days, and frequently entirely obscured the sun. Four days were free from cloud, and rainfall, with very unequal distribution, extended over 11 days, and amounted in the aggregate to 3.05 in., which exceeds the accustomed mean by nearly one inch. From the 8th to the 28th no rain fell—or rather during that time there was no appreciable gauge. Tropical winds predominated and occasionally they were high and squally, but once only, at the end of the month, attained the force of a gale. The estimated average temperature of July is 61.07 deg.; this year it exceeded that amount by 3 deg. The maximum of ozone was registered on every day but one.

## AUGUST.

But one solitary cloudless day during the month. The predominant modification was the cirro-cumulo-stratus, or thunder cloud. On the 17th masses in two strata and adverse wind currents formed rack and scud, and undulating waves of cirro-cumulus frequently overspread the sky. On the 6th and 7th, 8th and 9th, cold, high, tempestuous winds blew from S.W., sometimes with the force of a hurricane. On the 16th and 17th equatorial gales again prevailed, and produced considerable damage on our coasts. Barometric oscillations were frequent, but limited in range; the highest point attained was 29.72 in., the lowest 29.00 in., so that the entire variation was scarcely three-fourths of an inch. Up to the date of the 20th the mean temperature was considerably below the standard, but on that day a change occurred, and the thermometer rose and registered consecutively above the average until the 29th. The highest morning reading, at 10 A.M. on the 24th, was 75 deg., and the lowest, on the 4th, 59 deg.; the range, therefore, was 11 deg. The maximum divergence between day and night temperature was 27 deg. Rain fell on 18 days, and was below the average by 0.15 in. Lightning and thunder, electric cirri, haloes, and other meteors were frequent, and ozone began to decline. The 10th, 15th, 22nd, 29th, and 30th were periods of antozone.

## SEPTEMBER.

This month was characterised by the prevalence of wild, tempestuous gales, and excessive rainfall. The wind on 25 days blew from W. and S.W., and on the remaining days came in complication with N. and E. Tropical gales from S.W., extending throughout England, raged on the 2nd, 5th, 6th, 11th, and with somewhat mitigated force on other occasions. On the 24th, at 11 P.M., a cold atmospheric wave passed over Frant, Sussex, and produced transient condensation and sent down the thermometer several degrees. The mean temperature of the month was 7.06 deg. lower than that of last year, thus bringing it into close proximity with the general average of the season. The variation of the barometer was 0.10 within the inch. Rain fell every day from the 1st to the 27th, and amounted to upwards of 6.50 inches, which is more than 4 inches above the mean. Ozone continued to decline, and was below the average, but there was no apparent period of antozone. Fogs, light mists, and abundant dews occurred throughout the month,

sometimes producing complete atmospheric saturation, when external objects streamed with their accumulated condensation. Lightning and thunder visited the North and East Ridings of Yorkshire on the 16th, and slight shocks of an earthquake are reported to have occurred in Devonshire.

## OCTOBER.

A month of cloud and gloom and sunless days. On five or six occasions the hygrometer denoted complete saturation. The predominant combination of winds was E. and N.E. On the 18th a tropical gale occurred, but on the whole the action of winds was very moderate. The diurnal oscillations of the barometer were considerable, but limited in extent. A lunar rainbow, succeeded by a dim gray halo, appeared on the night of the 23rd. They were followed on the succeeding day by copious rainfall and heavy radii of cirro-stratus from N.W. Rain fell on seven days, and amounted, in gross, to 1.90 in., which was below the average by 0.18. Ozone again fell below the mean, and there were several well-marked periods of antozone.

## NOVEMBER.

Mensis Mirabilis.—The marvellous epoch of meteors. This month was marked by destructive gales, disastrous floods, and other signs of violent atmospheric perturbation. The rainfall was of very unequal distribution, and some of the northern counties were deluged by successive torrents, while others were visited by scarcely their normal average. One day alone was free from cloud, the prevailing type was the composite, or rain cloud, often in varied and beautiful modifications. The complications of wind from W. greatly preponderated, and the gales were generally equatorial. The first frost of the season occurred in Yorkshire, on the night of the 10th, of sufficient severity to blacken or destroy the tender annuals; but generally the month was marked by unusually high temperature. The night register, on several occasions, was 50 deg., and twice only, on the 20th and 21st, it fell below freezing. Ozone continued to exhibit a deficiency, and there were several periods of antozone.

## DECEMBER.

The past month was ushered in by a cold S.E. gale, and such depression of atmospheric temperature as gave promise that Christmas this year would assume his ancient prerogative, but the wind having lulled, the thermometer rose upwards of 20 degrees, and the frost of the previous night was followed by a warm equatorial wind from S.W. Several minor gales occurred during the month, and high and squally winds, which committed considerable damage. There were two cloudless days, and twenty-two days on which a canopy of rain-cloud overspread the sky. The highest reading of the barometer was 30.45 in., and the lowest 29.35 in., thus denoting a range of 1.10 inches. Atmospheric temperature attained its maximum on the 4th, when it registered 55 degrees in the morning, and 54 degrees by night. The lowest was on the night and morning of the 2nd, when the respective readings were 28 and 31 degrees; during the remainder of the month the temperature, with one exception (on the 31st), never sank below freezing. Rain fell on twenty-two days, and amounted to two inches, which is fractionally below the average. Ozone was very scantily developed, and there were nine periods of antozone, when the tests, after due exposure, remained pure and uncoloured. The hygrometric condition of the air was tolerably uniform, and one day only denoted saturation. The rate of mortality was below the average.

Thus has passed away this memorable year, leaving in indelible characters traces, upon living witnesses, of its wonderful phenomena and antagonistic manifestations. No theory has yet been propounded of the dynamics of atmospheric combinations, but the day may not be far distant when even these recondite mysteries shall be solved by the human mind.

## Correspondence.

### ON THE PROPERTIES OF OZONE—A NEW TEST FOR BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I believe I have discovered a most beautiful and delicate test for blood, but as it is not quite three weeks since I first tried it, I may learn, after a time, that it is not quite as reliable as I now think it. I borrowed the idea from Schonbein, who says, "Blood-globules, on addition of tincture of guaiacum

and oxygenated water, produce a blue colour, so characteristic, that a very slight trace of the globules can be recognised in this manner: water coloured with defibrinated blood, so as to be slightly red, forms a mixture of tincture of guaiacum, and oxygenated water blue, markedly and quickly. I recommend this re-agent—the most delicate I am acquainted with—to the notice of physiologists and those who interest themselves in the application of chemistry to medical jurisprudence." Following out Schonbein's views that ozone cannot be formed without the simultaneous production of antozone, I was led to try the effect of ozonized ether and tincture of guaiacum on blood; the reaction was immediate, and resulted in a most beautiful and, I think, permanent blue. I send you three specimens, marked one, two, and three, and also painted in water colours, a very fair representation of them as they appeared a few hours after the test was applied. By this test it is quite easy to detect the smallest possible trace of blood, old or fresh, and on any fabric. It seems to be chiefly the blood-globules that give rise to the reaction. Albumen slowly produces a rather dull green, quite different to that produced by blood-globules. You will find Schonbein's theory of the reactions in an article headed "Action of Oxygen on the Blood," published in THE MEDICAL PRESS AND CIRCULAR, dated, I think, June 27th and July 4th. I wish I could send you some of my ozonized ether, and some of my ozonized essential oils. I have recently tested their power of destroying the product of decaying organic matter in the closets of a large public school. Before I operated on them the stench was intolerable; now the atmosphere is not only pure, but agreeable. My plan is as follows:—In an ordinary case I suspend a piece of sponge or of flannel in the closet, and occasionally sprinkle over it a few drops of ozonized ether, combined with about a sixth or an eighth of some ozonized essential oil. Oil of lavenderis, perhaps, the pleasantest. Oil of capsia or of juniper answers as well. In my own closet I have adopted this plan for the last two years, and it has become quite famous for its purity.

In any bad cases I mix a small quantity of ozonized ether and some ozonized essential oil in a large quantity of pure rain-water, and wash the atmosphere with it by means of a garden syringe with an extremely fine rose.—I remain, &c.,

JOHN DAY, M.D.

#### MR. P. C. SMYLY'S REPLY TO MR. RICHARDSON ON HOLT'S DILATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Circumstances have prevented me answering Mr. Richardson's note sooner. In my short note I used the word misstatement, knowing that Mr. Richardson was well acquainted with the facts of the case, not only from the very able paper of my colleague, Professor Macnamara, when he introduced the instrument to the profession in this country, but also from the discussion at the Surgical Society of Ireland on a paper read by me on the immediate plan before the Surgical Society of Ireland when the differences between Perrève and Holt were discussed. Mr. Richardson has very dexterously pointed out the similarity between the two instruments. As to the differences I will allow Mr. Holt to speak for himself. I enclose you his letter.

I again ask the candid reader—Can an instrument brought before the profession in 1847, and rejected as dangerous, be the same as that introduced many years later by Mr. Holt, and received as valuable and safe?—Yours sincerely,

PHILIP C. SMYLY.

DEAR SIR,—Your letter in reference to the instrument that bears my name (which has been pointed out to me in the GAZETTE and MEDICAL PRESS AND CIRCULAR) has provoked a long explanation from Mr. Richardson, the personal part of which I refrain from referring to. The first of Mr. Richardson's remarks is contained in the following paragraph:—"But for all practical purposes, and in all the essentials, I repeat, the two instruments are identical in form and action, so much so that the instrument used by Mr. Holt is evidently a reproduction of M. Perrève's."

Mr. Richardson is in error. The instrument that I use is so different in detail that I am surprised it has escaped Mr. Richardson's observation; to my mind it is the difference between failure and success. In Perrève's dilator there are three errors—first, you have no positive means of knowing when the instrument is in the bladder; second, there is nothing to prevent the tube slipping from between the blades; and third, the directing rod projects so far beyond the handle of the instru-

ment as to prevent the tube being quickly thrust between the blades, so that the stricture or strictures may be fairly split. The drawing Mr. Richardson has given does not represent the instrument I now use, and although the principle is the same as Perrève's, the detail is so entirely different as to have insured the use of my modification with almost universal success, while that of Perrève has been entirely abandoned. Mr. Richardson has likewise alluded to the method of treatment, which here again is entirely different. Perrève did what Thompson is now doing, dilated rapidly. I, on the contrary, am never satisfied without the stricture is split. I conceive it to be a very great error to rapidly dilate strictures, and the quickness with which they recontract when so treated justifies me in that conclusion. Without wishing in the least degree to detract from the merits of Perrève's invention, I must assert that the instrument that bears my name is so far different from Perrève's that in mine you have all the elements of success, while in Perrève's there are errors which have made its use unsafe even in experienced hands.—Believe me, dear sir, faithfully yours,

Philip Smyly, Esq.

You are at liberty to use this note as you think fit.—B. H.

#### THE SYMPTOMS AND TREATMENT OF EPIDEMIC CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Crudelis ubique  
Luctus, ubique pavor, et plurima mortis imago.

What dark forebodings tinge with gloom my mind?  
I hear strange voices in the coming wind.  
Across my pathway, in the evening hour,  
Fantastic shapes and beckoning spectres pour.  
And in the clouds, careering through the sky,  
I see a thousand funerals fitting by.  
Are these prophetic of approaching death—  
Of cholera, that dread disease, of which the vital breath  
Deserts the frame—life's turmoil is o'er,  
And pain and misery rend the heart no more?

BUT should not the disease terminate under the favourable forms described, the third grade, or fully developed stage of the malady succeeds—namely, great vertigo, distressing nervous agitation, and restlessness, oppression of chest and precordial region, with total loss of muscular power, great collapse of the countenance, the eyes turned up, exposing the sclerotics, and surrounded by a deep and dark circle, sharp and contracted features, wild and terrified expression of countenance, and a feeling of immediate dissolution. The whole surface of the body—especially the hands, face, and extremities—assume a leaden blue or purplish hue; the extremities are shrunk, shrivelled, and sodden; the skin deadly cold, damp, and raw to the touch; the nails blue; the course of the large superficial veins are marked by flat lines of a darker tint than the adjoining skin; the tongue moist, flabby, and ice-cold, rarely contracted to a half or third of its size, dry, and of an ochre colour. Pulse, if perceptible, slow, thready, and irregular; profuse vomiting and purging of a wheyish or rice-water coloured fluid, which is ejected with great force, mixed with whitish foci; cramps commencing at the fingers and toes, rapidly extending to the trunk, or vice versa. The voice is nearly gone; respiration quick, imperfect, and most laboured; the patient painfully struggles for breath; inspiration is effected by immense effort, and expiration hurried and spasmodic, the expired air being ice-cold; he speaks on inspiration with a plaintive whisper, and utters but a word at a time with a painfully convulsive struggle, producing the well-known vox cholericæ; complains of burning heat and pains at the epigastrium (Leiperia), possibly owing to irritation of the solar plexus of nerves, parching thirst, and calls incessantly for cold water; sense of touch is much diminished, and deafness prevails; the integuments of the abdomen are drawn towards the spine and chest; the spasms usually clonic, occasionally tonic, and frequently rigidity of the muscles takes place; the secretions of the eyes, nose, and mouth cease; there is a total absence of bile, suppression of urine, and a faint and sickly odour from the body and evacuations. The patient expresses a wish to be left to his fate. Consciousness continues in the majority of cases to the end or nearly so. He now passes off imperceptibly, or respiration becoming slower, the anterior muscles of the neck contract strongly, the cheeks puff out in expiration, becomes incapable of swallowing, a quivering of the tendons of the extremities, or of the whole body comes on, he gives a convulsive sob or two, and dies.

Ordinarily death takes place in from six to eighteen hours on the first invasion of the epidemic.

The most common time of seizure is between the hours of one o'clock and five o'clock A.M.

This is the epidemic disease in its fully developed form, as first witnessed in India and Russia, and as we have had it presented to us in our own country, exhibiting uniformity of symptoms under every circumstance of locality, climate, and constitution of the affected.

The tongue, as I have observed, appearing in some rare instances contracted to a half or a third of its size, of an ochre colour and dry, is a symptom I have not seen noticed by any writer; those cases in which I saw it were in persons dispirited, suffering from inanition, and nude of all comfort, consequently very unfavourable cases—all in whom I saw it died in a very few hours.

Hæmorrhœa in this grade on its invasion is fearfully fatal; no time allowed for treatment, in fact, it commences in death.

The epidemic form appeared in this country in May, 1831, and in September, 1832, on both occasions in a most malignant form; in Sligo, especially, in the first twenty-four hours upwards of 100 deaths, seven medical men, died in one week in that town.

In the year 1831, of twenty-nine cases admitted to hospital in this town twenty-eight died. In the year 1849 during the summer there were many sporadic cases, especially amongst children, and in September of that year it became epidemic. In 1854 hæmorrhœa appeared in December and continued for months, especially in Cork and Belfast.

Those who recover from hæmorrhœa are not exempted from future attacks; on the contrary, I have found them more susceptible of the disease than those who never had any symptom of it. They become our sporadic cases in many instances. Your obedient servant,  
JOHN LENEY, M.D.

#### SALARIES OF POOR LAW-MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The Medical Officers of Workhouses and Dispensaries in Ireland may desire to know the result of the memorial of the Medical Officers of Sligo and Leitrim, addressed to Lord Naas in favour of salaries and superannuation pensions being paid from the Consolidated Fund. The Chairman and Secretary presented the Sligo and Leitrim memorial, and had a favourable reception. Lord Naas seems sincerely disposed to legislate for our interests. He wishes us every success, admits that we are not adequately remunerated, and fears that where officers can have private practice it would be difficult to establish our claims to superannuation pensions. I replied that our private practice was destroyed by red ticket practice, which any one can obtain who may apply, and once a ticket is tendered a fee could not be accepted even if it were offered, that not a single practitioner could or did exist on private practice alone in the counties of Sligo and Leitrim, that I refused midwifery practice beyond my district, lest I should disappoint applicants upon visiting tickets in my district, that the Sligo Resident Medical Officer of the Lunatic Asylum could be absent daily upon out-door private practice, and could retire upon full pay after twenty years service if infirm. His Lordship seemed surprised to hear this. I need not proceed further on the interview. I believe that if the Medical Officers and Boards of Guardians of Ireland petition the Government in favour of our salaries and superannuation pensions being paid from the Consolidated Fund, that both will be granted. We, of course, could not expect Lord Naas to declare his sentiments on the subject, but that his Lordship is well disposed to act justly towards the Medical Officers I feel convinced. Will all unite now or never to represent their strong claims?

Half the Poor-law medical expenditure in England being paid from the Consolidated Fund for the last twenty years, gives Ireland a strong claim now, which was recognized by a vote of the House of Commons last session, through the combined influence of Irish members of all parties upon the late Government.

If Irish members combine again upon the measure we now solicit they will succeed. We have the support of the five members for Sligo and Leitrim in our favour.

It would appear that close on two million pounds are due to Ireland, which sums England received towards her poor-law medical expenditure during the last twenty years. Why should not all urge their common claims now, and their representatives to support them? What we seek would not only relieve the poor-rates immensely, but remove Medical Officers from the tender mercies of Guardians, many of whom are very uncertain in their public conduct.

I refer Medical Officers to the Sligo and Leitrim memorial, published in your issue of the 26th December. May we hope that all will address Lord Naas on this important subject.—  
Yours truly,  
J. TUCKER, M.D.

### LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR DECEMBER, 1866:—

Anderson, John Albert, Cavan, L.R.C.S.I. 1866, M.D., Q.U.I. 1866.  
Gogarty, Henry Joseph Kelly, Dublin, L.R.C.S.I. 1864, Fell. 1866, do. do.  
Brown, Henry, County Antrim, L.R.C.P.Edin. 1866, L.R.C.S.Edin. 1866.  
McCarthy, Florence, Dublin, L.A.D. 1866.  
Dwyer, Henry, Dublin, L.R.C.S.I. 1866, L. 1866, and L. in Midwif. 1866, K.Q.C.P.I.  
Boake, Wm. John Slade, Dublin, L.F.P.S.Glasg. 1866, L. in Med. Univ. Dub. 1866.  
Cooper, Charles, County Cork, L.A.H.Dub. 1866, L.F.P.S.Glasg. 1866.  
O'Connor, Alfred, County Dublin, L.R.C.S.I. 1866.  
Beatty, John Guinness, Dublin, L.R.C.S.I. 1866, L. 1866, and L. in Midwif. 1866, K.Q.C.P.I.  
Manning, Leonard Archibald, Dublin, M.B. Univ. Dub. 1864, L.A.H.Dub. 1865.  
Singleton, William, Dublin, L.R.C.S.I. 1843, M.D. Univ. Glasg. 1845.  
Fitzgerald, R. Gerald, Dublin, L.R.C.S.Edin. 1866, L.K.Q.C.P.I. 1866.  
MacAlevy, R. Peel, County Down, L.R.C.S.Ed. 1866, M.D. Q. Univ. Irel. 1866.  
Robinson, Richard, Golden Ball, County Dublin, L.R.C.S.I. 1865.  
Neary, Bernard John, Dublin, L.R.C.S.I. 1865, L.K.Q.C.P.I. 1866.  
Hazlett, Henry James, Lurgan, County Armagh, L.R.C.S.I. 1866, L. 1866, and Lic. Midwif. 1866, K.Q.C.P.I.  
Keelan, Bernard, County Monaghan, L. 1866, and L. in Midwif. 1866, K.Q.C.P.I., L.R.C.S.I. 1866.  
McGann, Terence Joseph, County Clare, L.R.C.P.Edin. 1866, L.R.C.S.Edin. 1866, L.A.H.Dub. 1866.  
Alt, Nathaniel William, County Dublin, L.R.C.S.I. 1866, L. 1866, and Lic. Midwif. 1866, K.Q.C.P.I.  
Ritchie, James Hutton, Belfast, M.D. 1866, and Mast. in Surg. 1866, Qu. Univ. Ireland.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The vacancy in the Court of Examiners of the College of Surgeons, caused by the resignation of Mr. C. Hawkins, was filled up on Thursday last by the election of Mr. E. Cock, Guy's Hospital, the next senior candidate on the Council after the one last elected, viz., Mr. Quain. Mr. Cock became a member of the Council just ten years ago. Mr. Hawkins is still connected with the College as its representative in the General Council of Medical Education and Registration.

DUBLIN OBSTETRICAL SOCIETY.—SATURDAY, 12TH JANUARY.—1. T. E. Beatty, on Rigid Perineum. 2. G. H. Kidd, on Cephalotripsy. 3. J. A. Byrne, of Case of early Abortion, Hæmorrhage, Morbid Adhesion of Placenta—Removal. 4. S. L. Hardy, Case of Hematemesis in an Infant.

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

Every MS. should bear the Name and Address of the Sender.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

### ERRATA.

In the report of Mr. Richardson's case of Stricture of the Urethra, in page 19 of our last number, for *critical* read *cortical*, and for *tasa* read *Naasa*.

In our report of the Address delivered by Dr. Butcher before the Surgical Society of Ireland, in the 16th line of the 20th page of our last number, for *good* read *fixed*.

### BOOK RECEIVED.

Lectures on the Study of Fever. By Alfred Hudson, M.D., &c. 8vo. Dublin, 1867.

 SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

(Continued from page 536, vol. ii, No. 48, 1866.)

OBSERVATIONS ON THE TREATMENT OF THE DIABETES  
 MELLITUS.\*

SINCE the publication of Doctor Rollo's Treatise on the Diabetes Mellitus, this disease has been investigated with more than ordinary attention; and, though no absolutely curative plan of treatment has as yet been discovered, still considerable progress has been made, and the disease has lost somewhat of its hopeless and intractable character. Much was expected from Dr. Rollo's mode of treatment by animal diet; the efficacy of which was, at first, scarcely doubted. However, like other remedies which have, for a time, been high in public estimation, it has lost much of the character it had acquired; and will be found, I fear, greatly to disappoint the expectations of those who are disposed to place much reliance upon its virtues. An exclusively animal diet may, no doubt, and often does, alter considerably the sensible properties of the urine, and materially diminish its quantity; but even with the few who can endure, and will submit to such a restriction, it will be found to effect but little towards the removal of the disease. A partial adoption of this regimen will, however, be useful, and much merit is undoubtedly due to Dr. Rollo, not only for his discovery respecting the change produced in the saccharine urine, by a total abstinence from vegetable matter; but also for the valuable light which his labours have thrown upon the nature and treatment of this terrible malady.

Amongst the remedies hitherto employed, opium, in very large doses, ranks highest; it possesses the property of checking and restraining the flow of urine, and depriving it of many of its morbid qualities. Its effects, however, are of a transient nature; when the medicine is withdrawn, the complaint recurs; it may again and again check its progress, but the tendency of the disease towards a fatal conclusion will not, I apprehend, be ultimately prevented. A permanent cure of the diabetes mellitus has rarely been accomplished.

A perfectly successful mode of treatment yet remains to be discovered. Every step which is made towards the attainment of this desirable object, is in itself valuable, and may also lead to still further advances; till, at length, we may become possessed of the ability to rescue a considerable proportion of those who are affected with the disease, from a lingering and miserable death.

A well-marked case of the diabetes was, not long since, placed under my care. From the wish to afford all possible relief, I anxiously referred to every source whence useful information might probably be derived, and was thereby led to an attentive perusal of the several treatises and detached cases of this disease, which have, from time to time, appeared. In the works of the older writers, little, if any valuable matter respecting the treatment will be found; indeed, until the period at which Dr. Willis made the curious discovery of the existence of sugar in diabetic urine, all the recorded histories of this complaint are marked by vagueness and uncertainty; and are as applicable to any form of diuresis, as to that in which the urine

is saccharine. While employed in turning over the several works written on this subject, my attention was particularly arrested by the following important considerations: First, in many of the cases whose histories are recorded, the earliest disturbance in the general health could distinctly be traced to some cause acting upon the skin, and producing derangement of its functions. Secondly, every case of the diabetes mellitus is accompanied with a peculiarly morbid condition of the skin. In truth, I know not any disease in which this symptom is so uniform and so remarkable. Thirdly, none of the remedies employed produced the slightest beneficial effect, until the skin began to relax, and a sweat to appear on the surface.\*

These considerations led me to turn my attention more particularly to the state of the skin, and suggested the probability of advantage arising from the application of vapour to the whole surface of the body. The vapour bath was employed. The impression made upon the disease by the frequent use of this remedy surpassed my expectations. Its salutary effects, in giving a new action to the skin, were immediately perceptible. The perspiration having been afterwards maintained by warm clothing, and continued bodily exercise, the patient daily improved in health; and at length quitted the hospital, under the conviction of his disease being wholly removed. Before entering upon the particulars of this case, I shall briefly state two observations obtained, the one from Dr. Rollo's book, the other from a treatise written by Dr. Latham. These observations appear to me peculiarly important; as, in both instances, the only operative remedies were those which established upon the surface an abundant perspiration. In the first, the effect was produced by the tepid bath; in the second, by bodily labour. To these facts an additional value should also be attached, because, unwarped by any theory, they are simply and as it were accidentally stated.

In the second edition of Rollo on Diabetes, p. 183, there is a communication from Dr. Gerrard of Liverpool. In the case given by Dr. G., the first observable symptom was a diminution of habitual perspiration; afterwards it totally ceased; and at length "the cuticle became unnaturally dry, harsh, and rough, and to all appearance dead, and incapable of perspiration, absorption, or any kind of transmission." With this state of the skin was connected the ordinary symptoms; thirst, increased appetite, languor, debility, and saccharine diuresis.

In the sole view of determining, by experiment, the existence or non-existence of cutaneous absorption, this patient was immersed, every successive or alternate day, in water raised to a pretty high temperature; the weight of his body having been carefully ascertained, both before and after each immersion. An attempt was made to restrict him to animal diet; medicine of every kind was intentionally withheld. The warm bath was first used on the 12th of February. On the 22nd, there was a considerable diminution of the quantity of urine; its smell was urinous, and the extract less sweet; the weight of the body was increased, and it was observed, the dead cuticle began to come off.

24th. On this day he used the bath at the temperature 100°, and remained in it fourteen minutes.

\* See two cases of Diabetes treated by opium. *Transactions of the London College of Physicians*, vol. iv. In case I. it is stated, p. 198, that the "opium produced considerable perspiration, and on the following morning the urine was no longer sweet. The patient had felt great relief from languor since the opium had been resumed." In Case II. p. 208, it is observed that, "during the period in which the dose of opium had amounted to ten grains (taken four times in the day) the patient had perspired profusely, had been sleepy and giddy, but had suffered no other inconvenience; the urine had a natural appearance and odour, and yielded a very considerable extract." A case is recorded by Dr. Darwin, in which opium produced salutary effects, at a time when it caused the patient so to sweat, "that large drops stood on his face, and all over him." Another case is mentioned by the same author, in which a course of astringent and tonic medicines did not in the least benefit the patient. Opium was at length given; it excited profuse perspiration, and great relief ensued. Emetics have been useful, so far as they have been effectual in determining to the surface. The Hepatized Ammonia has also had the effect of promoting perspiration. Antimonials, when effectual in exciting diaphoresis, have likewise been found useful. Blood-letting and the warm-bath are valuable remedies, and their utility will be found proportionate to the power they possess of re-establishing the functions of the skin. See *Watt on Diabetes*, pages 27, 28, 29, 36, 35, 151, 152, 155.

25th. "The dead cuticle is peeling off; and he is obviously improving in every respect, and gaining weight." Bath continued at the same temperature, and employed every day till the 20th of March.

For several days, at the beginning of March, he lost ground, in consequence (as I conceive) of considerable disorder in the stomach and bowels. During the continuance of this derangement in the functions of the abdominal viscera, the cuticle did not come away as before, nor did the patient sweat. On the 21st of March, the non-existence of cutaneous absorption having been satisfactorily proved, the warm bath was laid aside.

28th. "He has had a considerable and general perspiration last night; his thirst and appetite are moderate, and he is quite free from pain." At this time the disorder of the bowels appeared to subside; the functions of the skin became more natural; and he began evidently to gain ground.

April 7th. He used the warm bath to cleanse his skin, when a large quantity of the dead cuticle came off. Cold bath ordered.

8th. Urine four pounds thirteen ounces; it is not sensibly sweet. He felt very warm and comfortable after the cold bath, and rested well at night; his appetite and thirst are moderate. He was now a second time thrown back by disorder in the digestive organs; but soon afterwards he began again to improve.

29th. Urine three pounds three ounces. "He had a copious perspiration in the night, which continued about four hours."

May 1st. "He perspired much in the night, but it does not weaken him."

6th. On this day it was discovered, that the patient did not adhere to the plan of animal diet longer than the first fourteen days. During the remaining (as is distinctly stated by the author himself) "he partook, with the other patients, in the common mixed diet of the house."

17th. "Urine four pounds ten ounces; it is neither sweet, nor in any over proportion to the fluids taken in; nor will it ferment, although he has lived chiefly on vegetable matter and milk, since the 6th instant. He has had copious perspirations these two nights past."

25th. "He was discharged from the Infirmary, to all appearance cured of the disease; which, to his own thinking, has long been the case; and to the opinion of his being *even cured*, I have no hesitation in subscribing."

This case, the details of which are in Dr. Rollo's book, possesses peculiar value. Medicine was not administered; nor was animal diet, except during the first fourteen days, adhered to;\* and yet there is here presented to us as perfect an instance of recovery as any on record. To what then is the cure of this patient to be ascribed? Not certainly to a few days adherence to animal diet; for it was nearly three months after the exclusively animal regimen had been laid aside (and at a time too, when the diet was chiefly vegetable) that the most marked and decided amendment of the symptoms was manifested. Since, therefore, no medicine was given, and little, if any effect, can justly be attributed to the short restriction to animal diet, it obviously follows that the warm bath (which was not used as a remedy, nor was its efficacy in the least suspected) was, in reality, the one and only efficient means of cure. This opinion is likewise corroborated by the fact, that, in the same proportion as the morbid cuticle was detached, and abundant perspiration established, so did all the symptoms of the disease subside. The second observation derived

from Dr. Latham's book, I shall quote in his own words:—\*

"The first case I remember to have seen, was in the Radcliffe Infirmary at Oxford, under the care of the late Dr. Parsons, then Clinical Lecturer in the University; the impression of its being an incurable disease, which the medical pupils received from the Professor, was sufficiently fixed in their minds by the inefficacy of the remedies which were from time to time prescribed for the patient's relief; worn out with expectation, and despairing at last of receiving any benefit, he was at his own desire put upon the list of out-patients, and requested to come occasionally to the Infirmary, that the pupils might have the opportunity of seeing the progress of the disease, rather than with any expectation of a prosperous issue to the complaint: a few weeks elapsed before he returned to us, and to the great astonishment of all we found him improved, not only in his appearance, but also very materially in the urinary discharges. His own account was, that, weary of life, and destitute of every ray of hope, he had wandered about, as well as his strength would allow him, for a few days amongst his fellow-labourers of the neighbourhood, and finding, from this exertion, that his strength did not decrease, he was tempted to take a part in the work that was going forwards; that a copious perspiration very soon ensued, under which he did not feel himself weakened in bodily powers, but rather improved in spirits; that he renewed the same sort of easy occupation from day to day, with the same comfortable event; and that at last not only his spirits but his bodily strength was manifestly increased; his urine, however, was then neither perfectly natural in smell or taste or quantity, although in all these respects it was certainly much amended. He visited the Infirmary a few times afterwards at irregular intervals, and at last ceasing to attend, we concluded, from the progress made towards recovery, whilst he continued his attendance, that he probably had been fortunate in experiencing a cure. And had we been then as convinced of the efficacy of animal food in diabetes as we now are, we should probably have thought that the provincial diet of that district might possibly have contributed to his relief, for the poorer sort of labourers usually lived upon a large onion with fat bacon, and no great portion of bread." I fancy the reader will be disposed rather to attribute the amendment in the state of this patient's health, to the free perspiration caused by bodily labour, than to the large onion, or even the fat bacon.

I shall now proceed to relate the principal facts of the case of the diabetes mellitus, which I have lately had under my care; and which strongly illustrates the value of those remedies, by which a copious and continued diaphoresis is most certainly produced.

— Riddal, æt. 20, a shoemaker; hair and eyes dark; conjunctiva clear and pearly; lines of the muscles distinctly marked; complexion sallow; emaciation extreme; veins prominent and full; skin a dingy yellow, permanently arid, and glued apparently to the subjacent muscles; gums ulcerated; a small unhealthy ulcer on the right cheek; epigastrium tumid; tongue florid at margin and point, and covered in other parts with a thin whitish secretion; extreme listlessness, languor, and debility; a sensation of weakness (referred to the knees) so great, that it is with difficulty the weight of the body is supported; dimness of vision; sleep broken and disturbed; he is much distressed during the night by spasms in the lower extremities; though constantly placed before a large fire, a sensation of creeping coldness is always present. Appetite inordinate; thirst unquenchable; mouth clammy; digestion rapidly performed; a craving sensation recurs soon after food has been taken; costiveness; there is a constant desire to pass water, which is increased during the night. From twenty to twenty-two pounds of urine are passed ordinarily during the twenty-four hours; the bubbles remain on its surface; it is limpid and almost colourless; its smell peculiar, and not easily to be described; its taste very sweet; when

\* It is scarcely credible to what a degree an exclusively animal regimen is loathed by the diabetic patient. Dr. Gerrard in the narrative of the case referred to in the text, whilst expressing his disappointment at being deceived by his patient, speaks of the "irresistible propensity to more or less of vegetable diet, as one of the characteristic symptoms of the disease." (P. 223). So prone are such patients to practise deception in this matter, that the adoption of the animal regimen, during even fourteen days, seems to me more than questionable. My patient deceived even those in the ward with him; and devoured, in secret, the skins of potatoes, and every vegetable substance he could lay hands on. The loathing of animal food is so very constant a symptom, that there arises from this circumstance alone an insuperable obstacle to the cure of the disease by animal diet.

evaporated there remains an abundant extract resembling coarse brown sugar; pulse 88, full and throbbing; neither cough nor dyspnoea; such were the symptoms which manifested themselves at the time of his admission into hospital, which was towards the end of the month of December.

I obtained from him the following account of the state of his health, previously to the time of his admission: In the beginning of last November, he embarked at Liverpool, in a vessel destined for Dublin. He was then in perfect health; a violent storm came on; the loss of the vessel was hourly expected. He was four days at sea, and during the greater part of that time was to his knees in water; he was chilled with cold; and for the last two days there was not any supply of provisions. After quitting the vessel, he felt himself constantly chilly, and could not by any means (to use his own expression) "get warmth into him." A thirst so intense came on, that he was perpetually swallowing large draughts of water; he preferred cold drinks. In describing the symptoms, he dwelt a good deal upon an unusual dryness of the skin, and a total absence of perspiration, since the time of his sea voyage; his sight also grew dim; his bowels were costive. In consequence of the excessive keenness of his appetite, his complaints became a subject of ridicule; languor and debility, notwithstanding the large supplies of food, daily increased; and at length he found himself so weak, that he was obliged to abandon his ordinary occupation, and make the best of his way to town to seek relief.

On the first of February, ten ounces of blood were removed by the lancet; the serum was milky; the crassamentum firm; the loss of blood did not in any manner affect the symptoms. From this time, on to the 2nd of March, mercury was used, externally and internally, in large quantities; no fetor of the breath, no increased secretion of saliva, nor any other symptom indicating the presence of mercury in the system, was perceptible. Only whilst using that medicine, he evidently lost ground and became, by degrees, so very weak, that he was no longer able to leave his bed. His bowels were regularly evacuated by doses of castor oil and tincture of senna. His diet was chiefly vegetable; his ordinary drink the inf. lin. and water.

On the 2nd of March the vapour bath was used for the first time. No very perceptible effect was produced. This remedy was repeated on the 9th, 12th, 16th, and 26th. The symptoms still unabated: there was, perhaps, some slight accession of strength.

From the 2nd to the 27th of April, all treatment, except daily purgation, was laid aside. The flow of sweet, and almost colourless urine, in the course of the day and night, often exceeded twenty-four pounds. The necessity of assuaging his thirst, and voiding his urine, was so continual during the night, that he could scarcely obtain any sleep. He was now reduced to a state of alarming debility. On the 27th of April, he was again placed in the vapour-bath; half an ounce of the tincture of opium was mixed with the water which was to be converted into vapour. He remained in the vapour-bath twenty minutes. On being replaced in bed, syncope came on, from which he recovered very slowly; he then became feverish and hot; at length the skin gave way, and the whole surface of the body was soon covered with sweat. He felt, he said, immediately relieved; and on the following day was much better.

On the 4th of May, he was again put into the vapour-bath, to which the tincture of opium, as before, was added. There was not, on this occasion, any tendency to faintness: it excited copious perspiration, and he had a sound and refreshing sleep.

On the 10th of May, the following note was taken of his case: Strength improves daily; he feels much less languid; skin soft and perspiring; pulse 88; a whitish secretion covers the tongue; appetite less craving; improved sleep; he grows fat; gums continue ulcerated and sore; and the ulcer on the inferior maxilla is still open.

May 18th. The urine, almost colourless and very sweet, amounted during the preceding day and night, to full twenty-four pounds. His thirst was very urgent. His weight on this day was seven stone ten pounds.

May 22nd. A temporary diarrhoea, with griping pain, was produced by repeated doses of the colocynth pill. The urine, during the increased action of the bowels, was observed to assume an amber colour, and to acquire a urinous odour, to be much diminished in quantity, and to have a taste less sweet. The tongue was cleaner; the feces yeasty; the mouth parched; no perspiration; skin very itchy.

May 30. Urine, though more amber-coloured, amounts to twenty-one pounds; pulse 100; no perspiration; an exclusively animal diet, with lime-water and milk, had been for some time enjoined: the patient, however, devoured in secret whatever of vegetable food he could procure; he said that much meat at a time lay heavy on his stomach, and greatly oppressed him.

June 3rd. A remarkable change in the symptoms was observed; for the last twenty-four hours the urine did not exceed eight pounds; during the preceding day and night perspiration flowed generally and profusely; there was a great accession of strength, and diminution of thirst and appetite. The abundant and continued sweating was produced by laborious exercise, while the body was enveloped in thick flannel, and the weather unusually warm. The first efforts at bodily labour were difficult and reluctant. The patient in the morning, when commencing the work of the day, could hardly move his spade; he was, however, prevailed on to persevere: by-and-bye he began to work with more ease to himself; and before the close of the day, when perspiration was fully established, the labour was easy and the fatigue trifling. From this period to the beginning of July, medicine of every kind was abandoned. He worked very hard every day; was warmly clad, and sweated much. His food was principally vegetable; he daily gathered strength and weight; enjoyed sound undisturbed sleep, and felt himself so far relieved, that he was resolved to return immediately to his home and former occupation. From the slightly saccharine taste of the urine, and the continued ulceration of his gums, I strongly urged that he should not yet remove himself from medical superintendence.

July 27th. Bowels costive; urine sweet, light-coloured, and moderate in quantity; tongue much cleaner; free perspiration; he rose but once during the night; thirst, though much abated, continues; weight eight stone thirteen pounds. For several days past he had ceased to work; the vapour-bath has not been used, nor any medicine given; a perspiring state of the skin, however, has continued.

August 4th. He has been for some days restricted to a diet exclusively animal; he has adhered strictly (as far as I could learn) to the regimen prescribed; his ordinary drink was milk with lime-water and beef-tea; the weather was very warm, and the patient's body entirely enveloped in thick flannel. An itchy, slightly-elevated, pale-red eruption was thickly and universally diffused over the surface of the body. His pulse beat steadily 120 strokes in a minute, and was throbbing and full.

August 10th. Pulse still 120. Diet consists in eggs, beef, mutton, soup, and milk. The serum of blood taken yesterday from his arm was white, like milk; sixteen ounces of blood were at that time removed; his strength, by this evacuation, was not in any degree impaired; the pulse fell to 104; perspiration continues; urine, within the last twenty-four hours, has amounted to eight pounds; the taste not sweet; the colour a deep amber; sleep natural. This day he complains of thirst, which has not been the case for several days past.

On the 12th of August, after a meal of fat meat, he was seized with severe vomiting and retching, and spent a feverish and restless night. On the following day, the pulse throbbed strongly, and rose to 120; he loathed food of every kind, had intense headache, panted for breath, and seemed like one suffocating. Fourteen ounces of blood were removed; the appearance of the serum was altogether altered; it was now perfectly transparent, and had a slightly greenish tinge; those urgent febrile symptoms he attributes to the animal regimen, from which he had not for some days deviated. He said

that fat or rich meat particularly disagreed with him. Urine slightly saccharine; much more deeply coloured, and considerably less abundant; skin thickly covered with an eruption of the same nature as that already described. The dyspnoea was so urgent that it gave to his countenance an expression of wildness. He was very restless, and continually changed his position. His skin was intensely hot. The flannel dress was laid aside, and he lay uncovered, except by a single sheet. His thirst was not to be appeased, and his appetite was wholly extinguished; the epigastrium was tumid and painful. By pressure at that region of the abdomen, the dyspnoea and suffocative sensation were very much augmented. Leeches were frequently and numerously applied at the epigastrium; the bowels maintained in a lax state by the daily exhibition of purgatives, saline draughts repeatedly administered, and opium, in large doses, given at night. After each application of the leeches, the respiration became freer and easier. In a few days, the febrile symptoms subsided, and left him weak, languid, and emaciated. The rapidity, however, with which he regained health, and strength after the cessation of febrile action, was remarkable: his skin continued soft and moist, but not profusely perspiring; his pulse did not rise beyond eighty in a minute; his sleep was undisturbed; his appetite moderate; and there did not remain any inordinate thirst. The quantity of urine varied from six to eight pounds, during the day and night; it was rather light-coloured; the taste salt and slightly sweet; he weighed eight stone four pounds. Under these circumstances, towards the end of the month of September, he quitted the hospital. I saw him on the first of January, 1822. There was not any return of the symptoms; the skin retained its natural and softened feel; he weighed eight stone five pounds; his pulse was moderate; the expression of his countenance very much improved; though not exempt from thirst, it gave him no annoyance; his tongue was whitish; he felt strong, and alive to every enjoyment; he worked at his trade as a shoemaker, from an early hour in the morning, with little intermission, until late at night; his diet consisted of bread, butter, occasionally meat, fish, potatoes and gruel; the gums were very slightly ulcerated; the bowels, without medicine, were daily evacuated; the general quantity of urine, in the course of a day and night, varied from six to seven pounds; taste salt, slightly saccharine; colour still paler than natural.

Such are the leading facts which belong to this case. I regret that the specific gravity of the urine was not at any time ascertained, and that this fluid was not, during the progress of the disease, subjected to chemical analysis. Attention to these points would have rendered the history of the case much more complete. Such as it is, however, it exhibits, in a striking point of view, the powerful effects of copious perspiration, produced by the vapour-bath and muscular exertion, in controlling and restraining the symptoms of the diabetes. That many have attempted the cure of this disease, by diaphoretic remedies, I am well aware; but the attempt has been made rather through the medium of medicines taken into the stomach, than by means of remedies designed to act directly upon the skin. That internal remedies should have failed is not surprising, when we consider that the constitution of a person labouring under this affection will resist the action of the most powerful medicines, even when exhibited in the largest doses. It is singular to what an extent opium, antimony, and other drugs may be administered, and yet little or no effect be produced. The warm-bath has been used—but it has been used only occasionally; it has been employed as a secondary remedy, as one of minor importance, and not as one, which, if properly managed, is of itself sufficient to effect a cure. Its daily employment for weeks, nay months, may be requisite to bring about that relaxed and freely perspiring state of the skin, without which, whatever temporary abatement in the symptoms, or diminution in the flow of urine, may have taken place, not one step has, in reality, been made towards the accomplishment of a cure.

(To be continued.)

## Original Communications.

### CASES OF INTESTINAL OBSTRUCTION, ILLUSTRATING THE VALUE OF OPIUM AS A REMEDY.

By W. H. SANDHAM, M.R.C.S., Cork.

(Read Before the County and City of Cork Medical and Surgical Association.)

MR. F———T, æt. 20, healthy constitution, residing four miles out of Cork, suffered two months since from intestinal obstruction; it yielded to ordinary treatment in about thirty-six hours. *Second Attack.*—At 4 o'clock A.M., on 3rd December I was again sent for, and found him after taking a cup of salts and senna and a large dose of castor oil without any purgative effect. He complained of pain at the head of the colon and vomiting. There was no hernial tumour nor other systemic disturbance; pulse soft, full, and 80. I administered a large turpentine and assafoetida enema; left him two pills, cal. gr. iij., opii gr. j., to be taken every four hours, followed by a glass of salts and senna mixture every hour; of this he drank 8 oz.; no effect. Friday 4th, ten A.M. Still in pain; bowels above the obstruction tympanitic; tenderness limited to seat of obstruction. Gave three drops of croton-oil, two turpentine, and one tobacco injection this day. I remained with him this night. At 1 o'clock, being still in pain and rejecting everything, I determined on giving up purgatives by the mouth, and adopt the soothing plan; pulse, tongue, and heat of skin were normal. I put him on poppy stupes and 2 grs. of opium every two hours; vomiting and pain ceased immediately after second pill. I then put him on 1 gr. of opium every three hours. Saturday, 5th. No vomiting and little pain; system undisturbed; used large enemata morning and night; continued opium. Sunday, 6th. About two o'clock this morning he complained of inability to micturate, and his father becoming uneasy called in Dr. Edward Townsend. I preceded Dr. Townsend, and administered a large enema through an œsophagus tube with a stomach pump. He passed water without catheterism. Dr. Townsend added to my opium pill 2 grs. of calomel every three hours. Immediately after taking the second pill severe bilious, almost black, vomit set in. At my evening visit, 8 P.M., I omitted the calomel, and put him again on opium alone; vomiting at once ceased; used enema nocte-manè. Monday, 7th, 8 A.M. Found him tranquil, and pulse full, soft, and 74; not much abdominal tenderness, but tympanitic to such an extent as to define the transverse colon and stomach; gave large enema; in fact pumped away until he could contain no more, when mechanical distension alone caused it to pass off; no effect. At half-past four P.M. Dr. Townsend and I administered enemata as before, and added two grs. of aloes to the opium pill every three hours, and a glass of salts and infusion of roses, alternating with pill; to be stiped often, and have fowl broth and arrow-root; took some of the pills and most of mixture; no effect. Tuesday, 8th, nine o'clock A.M. Dr. O'Connor and I saw him, Dr. Townsend being feed off. I regretted the loss of Dr. Townsend, but was pleased his successor was a man of such large experience. We administered a copious enema, containing turpentine, oil, assafoetida, soap, and common salt, and to the opium and aloes pill of Dr. Townsend and myself, we added one-twelfth of a grain of strychnine every three hours. Six P.M. I saw him; used usual enemata, and continued pills. Up to this no systemic disturbance whatever; pulse 64. Wednesday, 9th. Tranquil; no vomiting; considerable tympanitis; enemata, stupes, &c., as before; ceased pills and ordered half oz. castor-oil and twelve m. tinct. opium every three hours; took them through the night; had a good night, and towards morning three liquid stools, like portions of the injections. Thursday, 10th. Dr. O'Connor and I concluding the bowel was about to resume its functions, omitted enemata, but con-

tinued oil draught, two in the day. Dr. O'Connor feed off. Six P.M. He took the two oil draughts; no alvine effect. I gave him a large soap enema, and he passed some scybalous matter, small in amount; two oil draughts during night. He this evening craved for food, and said he "felt satisfied some change had taken place." His abdomen was still very tympanitic, and whatever there was of tenderness was now over the sigmoid flexure of the colon, in the groin opposite that first pained. Friday, 11th, A.M. Three liquid stools; had fine night. To have tea and toast, beef-tea, arrow-root. Is in good spirits; swelling and tympanitis better. Six P.M. Had two feculent discharges, but none since taking sedlitz powder at three o'clock; gave soap injection. He passed a large quantity of broken down feces, complains of painful tenesmus, eats with a liking; region of stomach and transverse colon still tympanitic; no pain on pressure anywhere over abdomen. Saturday, 12th, ten A.M. Good night; took sedlitz powder at six A.M., followed by two satisfactory stools; gave soap enema, followed by another satisfactory result; feels much better; tympanitis greatly abated. Sunday, 13th. Better; another enema satisfactory. 15th. Soap enema again satisfactory. Feed off.

*Mr. F—t's Third Attack.*—On the 18th of February, 1863, again called in. Dr. O'Connor was four days in attendance, and during that period he used cal. and opium, salts and senna mixture, stupes and enemata, without effect. We agreed to treat him on the same principle as on the second attack—namely, avoiding purgatives by the mouth, and administering grain doses of opium every four hours, with copious enemata nocte-manerque; this treatment was followed with the same satisfactory results as before, so far as keeping vomiting and systemic disturbance quiet. Morning and evening copious enemata were given, until the 28th, when he had two encouraging stools; pulse tranquil, and 80; all through it kept steadily 96 to 100. Notwithstanding the continuance of opiates no symptom of narcotism presented. There was a marked difference between this and the second attack, in the remarkable absence of pain and tenderness. He had a sense of oppression from tympanitic distension, which was very great, but nothing more throughout; thirst was often urgent, and tongue brown and parched; lived on fowl broth all through.

March 1st. This morning his bowels acted freely without enemata, and in consequence Dr. O'Connor and I were discharged. The father was physicking him for three days before Dr. O'Connor saw him, so that the obstruction this time continued *nineteen days*—the second attack *fourteen days*. Such attacks as those now read most practitioners of any standing present must have met, but the history of three attacks on the same person must even interest such; but I have been induced to record them especially for the information of the students, who, I am glad to see, attend the meetings of our Society in large numbers. The second attack is a remarkable one; and the third is in every particular like it—first, for its obstinacy, never yielding a jot for twelve days; second, for the number of injections administered, in all about thirty—at one time consisting of turpentine, oil, and assafoetida; at another, soap suds, soap suds and salt, and even tobacco, cal. and opium pills to ptyalism, croton oil bolus, croton oil by itself, senna and salts, salts and infusion of roses, pills of opium and aloes, opium, aloes, and strychnine, castor oil draughts to the number of twelve, and from one o'clock A.M. on Friday, 4th, to Sunday, 13th, he took opium every three or four hours in doses of two grains, one grain, or the minimum, half a grain, throughout nine days and nights without one symptom of narcotism being induced. It was remarkable—*once he was put on opium*—how little the constitutional or systemic disturbance. Any medical man looking at him in bed, and examining his pulse, would at once tell the boy to get up for he had no illness. Dr. Watson, in his "Lectures on the Principles and Practice of Medicine," page 463, says:—"I know of no cases of disease more painful to witness or to treat than those which result from invincible obstruction of the intestinal tube;" and, again, page 467—"It is to these circumstances of irremediable disease that *opiates* are eminently adapted." Every practitioner present

knows well how painful it is either to witness or treat obstinate intestinal occlusion. But the history of the preceding incontrovertibly proves that opium is invaluable even in remedial cases—the persevering use of opium I look upon as the salvation of my patient, Mr. F—t, who, I am happy to say, is hearty and strong this day.

One word about calomel in ileus. I am strongly of opinion calomel is entirely contra-indicated once you are satisfied the bowel is constricted or obstructed, no matter from what cause. I think calomel does positive mischief, and in this way: you administer a scruple—ten or five grains as a purge at first; it fails to purge or pass per anum. It is then given every three or four hours, combined with opium. It is accumulating in the system, and what organ does it stimulate or seize on? The liver. Its secreting powers are increased, or the gall-bladder and its ducts stimulated; bile is poured out in large quantity; this bile cannot pass the obstructed bowel, and nature gets rid of it by vomiting; in fact, violent anti-peristaltic action is induced, and the patient thereby suffers intensely—this being invariably what I have witnessed whenever calomel was administered. Unless my mind changes much, I will in future oppose the giving of calomel in constricted or obstructed bowel affections after it has failed as a purge. To the young practitioner I would say—while there is life there is hope; never part your patient until death snatches him from you, for in many cases—like the attacks just read—your patience and perseverance will be crowned with success.

I forgot to mention that during the last attack, on two or three occasions I tried electricity (the interrupted current), but without effect. Dr. Watson, before quoted, writes, page 465—"The intestines may be torpid and insensible to ordinary stimuli, and really require strong rousing. Dr. Abercrombie mentions the case of a gentleman whose bowels were locked up by an accumulation, as the result showed, of black, hardened feces. The obstruction, which had resisted the most active purgatives, and was accompanied by an evident and painful distension of a part of the abdomen, yielded *at once* to the repeated application of galvanism to that part. Each application was *immediately* followed by a copious evacuation. Here the flagging muscular action was restored apparently by the galvanic stimulus.

From my experience of this remedy, I would deserve censure did I omit its use in future cases. When you have want of power or a semi-paralysed state of the muscular coat, I think it a stimulant and anti-spasmodic likely to induce active peristalsis. We can see before our eyes some of the effects of certain currents of electricity when made to traverse voluntary muscles in the human subject, and in frogs, &c.; but what effects should follow the same currents applied to muscles supplied by the sympathetics alone, I fear we are as yet ignorant of, and to this ignorance of the proper current to use, and the best direction to pass it, I attribute the want of success in such cases as those I have read; but I think the day not far distant when this knowledge will be arrived at.

#### REMARKS ON CHOLERA AND ITS TREATMENT; WITH CASE.

By G. KINLOCK H. PATERSON, L.B.C.P., L.R.C.S.Ed., &c

THE articles on cholera in THE MEDICAL PRESS AND CIRCULAR, during past months and recently, show that the profession are far from being at one in regard to the nature and cure of it, nevertheless in the discussions respecting which it will be admitted that there has been and still is shown very great ability, with much effort and earnestness, to relieve and cure as many of the affected, as possible, also a noble and kindly sympathy towards sufferers from cholera wherever it has made its appearance. It is but justice to acknowledge these public services for the relief of our suffering humanity. Perhaps at no time before was there ever so much written

about this epidemic as in 1866, both in our own country and abroad.

Bleeding in cholera—that is to say, in young and stout persons affected with cholera—if done early, ought to find not a few supporters for its use.

In 1849, when the cholera was in Dundee and Carse of Gowrie, I tried bleeding as a remedy to a small extent, in the early stage, with success. Also, I generally used the tincture of opium, although at other times I gave to some who were of delicate constitutions, and after being seized with vomiting, purging, and cramps, then tincture of the sesquichloride of iron, or steel drops; good results following from both. Evidently it is in vain, as far as I have seen, to look for any one remedy to suit all cases or stages of cholera. Those affected will, in my humble experience, always have most chance to recover when the means are early and properly adapted and adjusted to their individual conditions, and expertly applied, especially before their strength begins to fail from the progress and effects of the disease.

All my successful cases of cholera in 1849 were in the early or first stage of it; and I do believe had such not been timeously seen and means applied early, a very unfavourable statement would in regard to the latter have followed.

I am in favour of giving to the delicate, when attacked with cholera, the tincture of the sesquichloride of iron, alternated, if needed, with tincture of opium, in doses according to the severity of the case and age.

*Case.*—J. D., aged 19, female servant, was on 5th Nov., 1866, suddenly and violently seized with internal abdominal pain in the evening. I was hurriedly sent for; on my arrival found her having symptoms of what some writers call “cholera sicca;” soon afterwards cramps came on, affecting the upper and lower extremities; she complained very much of the latter while they lasted, and, when such had for a little subsided, of the pain in the abdominal region. There was no vomiting or purging.

Speedily I bathed her cramped hands with salted hot water, and kept them stretched out, and put her feet in warm water with mustard; laid a large sinapism over epigastric region, but on account of the pain returning now and then I gave her tincture of nux vomica to the extent of twenty drops, and in about half or three quarters of an hour she had an evacuation of her bowels, after which she began to feel easier, and by next morning she was much better, and did well.

## SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### LATEST VIEWS ON ANTISEPTICS AND CHOLERA CONTAGION, COLLATED FROM VARIOUS SOURCES.

The late epidemic, which seems to have now left our shores, has given us some amount of experience, which will no doubt be of considerable use in connection with contagious diseases generally. The subject of purifiers of contagious or offensive matter has been considerably sifted from a great deal of the chaff which surrounded it. Much of this confusion was, in many cases, due to the ill-advised advertisements, which have the sale of a proprietary article at heart more than the benefit of the community. Perhaps no more difficult subject has engaged the attention of the scientific world than the different phases of contagion, and the destruction of miasmatic effluvia. Before we take leave of it, it may be well to place before our readers a summary of what, at least, is the aspect of this subject at the close of the year 1866, which, in this respect, has been to us an eventful one indeed.

The following have been the disinfectants finally used by the Medical Officers in London:—Carbolic acid and M'Dougall's powder are those specially marked out by the Medical Officers for the parish of St. Mary, Islington. Dr. Gibbon published a separate handbill for the use of carbolic acid and the carbolic powder in the “Holborn district.” Sulphate of iron, with carbolic acid, were solely recommended for “privies and water-closets” at St. Giles's. Mr. Lionel J. Beale especially recommends carbolic acid for the disinfection of excreta, water-closets, and clothes.

In the district of St. Mary, Newington, also, carbolic acid is specially recommended for arresting the spread of cholera.

At Oxford some drains and sewers were disinfected by means of carbolic acid during last autumn, and the characteristic flavour of carbolic acid was soon after detected in the drinking water, to the great indignation (says the reporter) of the householders, who would doubtless have preferred the sewage, if undetected, to the flavour of carbolic acid, so easily detected.

That ozone has no effect on the presence or absence of cholera has been shown by Shultze, Voltolini, Du Methe, Lamont, &c. As regards the charcoal boxes recommended for drains, we learn that charcoal does not seem to disinfect or destroy cholera poison. The ships which were employed in transporting charcoal from Constantinople to the Crimea were ravaged by cholera.

Dr. Gibbon, Medical Officer of Health to the Holborn district, has reported to the Local Board of Works that whenever a death or removal of a cholera case occurred, he had instructed the inspector to retain the key of the sick room until every article of bedding and clothing had been plunged into a mixture of boiling water and carbolic acid, and he “considers this method of disinfection more effectual than the somewhat costly one recommended by the order in Council of burning every article.”

The Lords of the Admiralty have ordered that the use of Burnett's disinfecting fluid shall be discontinued in the Royal Navy, in consequence of several fatal cases of poisoning having occurred from its having been accidentally swallowed by seamen (Burnett's fluid being a strong solution of chloride of zinc). Carbolic acid is now to be used throughout the fleet.

Dr. Letheby's observations to the Registrar-General in connection with disinfectants may be summed up in a few paragraphs.

*Chlorine gas*, being a diffusive body, is best suited for the disinfection of places which cannot be reached by other disinfectants. It has been principally used for the disinfection of vaults of churches, &c. *Chloride of lime* was used in disinfecting about two thousand of the worst class of houses, by sprinkling it over the floors, and scattering it about the cellars and yards. Carbolate of lime was used in a similar manner to chloride of lime, but principally where the bleaching action of the latter would be an object. They must not be used together. The carbolate of lime should contain twenty per cent. of carbolic acid. *Carbolic acid* has been used as the sole agent of disinfection for privies, drains, and sinks, and for the sewers of public roads. *Chloride of zinc* is only applicable to the discharges from sick persons, but it is hardly applicable to any other purpose. (Carbolic acid must be the most efficacious for this purpose.—Ed. S.) *Chloride of iron* is used in the same manner as chloride of zinc. Permanganate of potash is only suited for the disinfection of drinking water.

Dr. Frankland writes, as regards the putrefaction of organic matter in river water, and also with regard to the temperature at which putrefaction and decay of organic matter in water takes place, to the following effect, in the case of the Duke of Buccleuch and others v. Alexander Cowan and others, recently tried at Edinburgh:—

“Where a river becomes sluggish, as where it is pent up by a weir, the quantity of organic matter, and also of mineral matter, increases, in some cases very considerably; but that is only the case in warm weather, and the temperature of the water must be 55 deg. Fahrenheit and upwards for this effect to be produced. The putrefaction of the mud in

the bed of the river ensues, and the previously insoluble matter becomes soluble."

The safest and most sensitive test of putrefaction in water is the relative proportion of oxygen to nitrogen in the dissolved gases. The river North Esk, as it flowed through the Duke of Buccleuch's grounds at Dalkeith Palace in March and June last, afforded striking evidence of this kind as to the effect of temperature upon the absorption of oxygen by the organic matter of water. It is only when the whole of the oxygen dissolved in water is consumed that the latter assumes a true and putrefactive condition.

On the 31st of March the temperature of the water in the North Esk was 38 deg. Fahrenheit, and the proportion of oxygen to nitrogen in the dissolved gases was  $O : N = 1 : 2.02$ . This is the normal proportion in water free from organic matter. On the 21st of June the river emitted a putrid odour; the temperature of the water was 60 deg. Fahrenheit, and the proportion of oxygen to nitrogen was  $O : N = 1 : 0.25$ ; thus the amount of dissolved oxygen was reduced to a mere trace, and the organic matter was in a putrescent condition.

#### ON THE ACTION OF GLYCERINE UPON METALLIC SALTS.

Antony Guyard, in a communication to the *Chemical News*, 30th November, 1866, points out certain cases where glycerine has the well known property, possessed in common by many organic substances, of concealing the ordinary chemical reactions. Oxides of nickel and cobalt are very indifferently affected by glycerine, if this substance is added in excess, and if potash or soda is added the whole forms an apparent solution, from which however the largest portion of the oxide is precipitated, simply by destroying the viscosity of the glycerine, either by diluting with water or by warming. Sulphate of alumina, sesquichloride of iron, nitrate of lead, protochloride of tin, are not precipitated by ammonia in the presence of a large excess of glycerine. Alumina, instead of being precipitated in its gelatinous form, will effect the shapes of dense flakes, which collect rapidly at the bottom of the flake, and which, if filtered, can be washed with the utmost facility. This property, the author remarks, will be found extremely useful in the preparation of hydrated alumina; the process can be slightly modified for this special purpose in the following manner: To the solution of the alumina salt, supposed to be pure, an excess of an acid and of glycerine is added, the whole is warmed, and then precipitated by ammonia.

Per oxide of iron is very soluble in ammonia and glycerine.

#### ON THE PRESENCE OF PROPIONIC AND BUTYRIC ACIDS, &c., AMONG THE PRODUCTS FROM THE DESTRUCTIVE-DISTILLATION OF WOOD.

Dr. Anderson has noticed the presence of some of the homologues of acetic acid in the mother liquors of acetate of soda. The butyric and propionic silver salts were separated and analyzed. The presence of Valerianic acid was inferred.

#### "ELAND'S BOONTJES."

This substance was analyzed lately by Dr. Attfield. It is a species of acacia, yielding food, medicine, and tan to the natives of South Africa. They extract an oil by boiling, which is used as food. An infusion of the root is employed as a gargle, and also as an astringent in dysentery. The root is also used for tanning, and contains 13 per cent. of tannin. The seeds contain about 30 per cent. The percentage of nitrogen in the kernel is 3.6, and in the integument 1.03. Dr. Attfield says it probably exists in the state of vegetable albumen.

#### SULPHIDE OF AMMONIUM.

Mr. Spence, in a communication to the Manchester Literary and Philosophical Society, gives the following easy method of manufacturing pure sulphide of ammonium on the large scale:—He mixes soda waste, or gas lime (impure sulphides of calcium), with half its weight of sulphate or chloride of ammonium, and then blows steam into the mixture, and passes the vapours through a condensing

apparatus; the distillate is pure sulphide of ammonium. Sulphuretted hydrogen, says Mr. Spence, when referring to an accident which happened in connection with this substance, is most powerful in its effects on animal life, but when combined with ammonia it seems even more active. One peculiarity of it, in both forms, however, seems to be that if you escape with life, it leaves no bad effects afterwards.

The result of Mr. Spence's process is no doubt the production of a hydrate of the monosulphide. There are great numbers of the sulphide all procurable by distilling any corresponding sulphide with a salt of ammonia. The heptasulphide, however, of which there is no corresponding sodium or potassium salt, seems to be the most stable of the polysulphides of ammonia, and is no doubt the most valuable commercial salt.

#### ON A FATTY ACID, &c., FOUND IN HUMAN URINE.

M. E. Schunck, in two communications contributed to the Royal Society, gives us another instalment towards the catalogue of numerous products derived from the above source. The first is a description of a process by which he separates a fatty acid. The process consists in passing urine, which has already been filtered, so as to separate all insoluble matter, through animal charcoal. The charcoal completely decolorizes and deodorizes the urine: The charcoal, after being thoroughly washed with water, yields a brownish fatty matter on boiling with alcohol. This is further purified by treating with water. This fatty acid has properties characteristic of the group to which palmitic and stearic acids belong. It is white and crystalline; has a pearly lustre; melts at 54 degs. C.; volatilizes unchanged when heated; and is easily soluble in alcohol and ether. It is also soluble in the alkalies and alkaline carbonates, yielding solutions which froth. The author thinks it is a mixture of stearic and palmitic acid (margaric acid), but the quantity obtained was too small for analysis. How this acid, if a normal constituent of human urine, comes to be dissolved in an acid fluid (urine) is a matter of some interest; the author's researches do not, however, throw any light upon this subject.

In another communication the author says that he procured oxalurate of ammonia from the washings of the above fatty acid. Whether this salt is a normal constituent of human urine or not he cannot say, but its presence, he says, affords an easy and satisfactory explanation of a phenomenon which has, until now, been unexplained—viz., the formation of oxalate of lime in urine, long after its emission. It is, doubtless, owing to the decomposition of oxaluric acid, which takes up water, and splits up into urea and oxalic acid, the latter then combines with the lime contained in urine.

#### ON THE CONCRETIONS FOUND IN PORK.

M. Virchow has often found in the flesh of pig some concretions which experiments have proved to be formed of crystals of guanin. They are found especially in the cartilage, &c., which surround the knee.

The concretions examined by M. Begemann are not organic. They consisted of a mixture of phosphate and carbonate of lime, which had already been observed. Nothing authorizes us to see in them the remains of trichina cyst.

The author speaks again of concretions observed by M. Leuckart, formed of stearine and palmine. These are developed in smoked meat.—*Journal de Pharmacie et de Chimie*.

#### NON-EXISTENCE OF CAROTINE.

The red crystals found in the ligneous parenchyma of the carrot, and which have been considered as due to the immediate principals, carotene and hydro-carotene, are, according to MM. Frorde and Scaur, nothing more than cholesterine coloured by a red pigment.

MM. Frorde and Scaur also ascertained the presence of asparagine, and, they believe, of bimalate of lime.

Although the supposed carotene yields substitution compounds with chlorine and bromine, which resemble those

obtained by similar means from cholesterine, the researches of M. Husemann, performed some years since (An. Ch. Pharm. cxvii. 200), seem to point to some difference between these products. But there is nothing extraordinary in the presence of cholesterine in vegetable substances, as it has been noted before.

#### ACTION OF WATER UPON LEAD.

The cause which tends, most, towards attacking lead, when immersed in distilled or rain water, is, according to M. Stalmann, the presence of a small quantity of ammonia. On distilling water the first portions will be found most corrosive. A water containing 0.0015 in 100 is very active. Nitric acid if present renders it equally active. Small quantities of nitrate of ammonia are without influence. The air and carbonic acid have a considerable action upon lead, but when deprived of the presence of air carbonic acid is without action.

### MEDICAL GLEANINGS.

(From the British and Foreign Medico-Chirurgical Review.)

#### ON THE HISTOLOGY OF THE BLOOD-CORPUSCLES.

By PH. OFSIANNIKOF.

PROFESSOR OFSIANNIKOF believes himself to be justified in concluding from his experiments that the blood-corpuscles of most if not all animals possess an investing membrane or proper cell-wall, which reacts differently from the cell contents when exposed to the action of water, serum, and other fluids, and under certain circumstances possesses a remarkable degree of firmness. The behaviour, however, of different corpuscles taken from the blood of the same animal with these fluids often differs considerably. He has observed that the process of crystallization occurs in the cell contents whilst yet enclosed within the membrane, though sometimes this takes place with more, sometimes with less, facility. He alludes to the variety of forms that have been depicted as the result of the action of certain reagents upon the corpuscles, but declares that he has observed nearly all these forms in the corpuscles whilst swimming in blood-serum. He has found the entire substance of the blood-corpuscles, cell-membrane, contents and nucleus, when this last is present, dissolve after a time completely in serum, water, solution of sugar, and in other fluids. Beautiful crystals may be obtained from frogs' blood (but not from the blood of man), treated with solution of sugar mingled with alcohol.—*Bulletin de l'Academie Imperiale de St. Petersburgh*, t. viii., p. 561.

#### ON THE CONSTRUCTION OF A MICROSCOPIC SLIDE CAPABLE OF BEING HEATED, AND ON THE EXAMINATION OF THE BLOOD BY ITS MEANS.

By MAX SCHULTZE.

FOR the particulars of the construction of Max Schultze's slide we must refer to the original, only observing that it consists essentially of two metal arms, extending laterally, to which the flame of a spirit lamp can be applied. The temperature is ascertained by a small thermometer, and is regulated by the part of the arms to which the lamp is applied. One of V. Recklinghausen's moist chambers is an important adjunct.

In examining the blood, the temperature was maintained at about 100° Fahr. As regards the *white corpuscles*, Schultze found constantly in his own blood and in that of some of his friends, some white corpuscles of smaller size than the red corpuscles, some of equal size, and, lastly, the well-known typical form; in these last the most lively and vigorous movements were perceptible, processes being thrown out which were followed up by the whole corpuscle, exactly as in the movements observed in the Amœbæ. In no instance was he able to determine the existence of a membrane on the surface of these colourless corpuscles, and its absence was also rendered highly probable by the taking up into their interior of certain colouring matters, as carmine and indigo, and of milk-granules. They thus appear to be membraneless cells, and they therefore belong to the same series of cells as the blood-cells of the Invertebrata.

The movements of the colourless cells cease in man after two or three hours at 100° Fahr. If the temperature is much ele-

vated beyond this point they quickly die, but if it be lowered to near 32° Fahr. the movements may continue even for as long as twenty hours.

The *red corpuscles* never exhibited any movements, but when raised to 125° Fahr., at which temperature the white corpuscles were killed, the red underwent a change of form hitherto unnoticed; at first they were unchanged, then indentations occurred at the margins; then roundish fragments, at first with pedicels, detached themselves. The end of all was that in the blood-fluid only small spherical bodies of darker colour remained, the largest being always smaller than an unaltered blood-disc, and the smallest quite a minute granule. Schultze arrives, from his experiments—not only on man, but on the dog, rabbit, calf, and guinea-pig—at the conclusion that the coloured corpuscles of the blood are also destitute of any investing membrane, and he is herein in accord with Rollett and Brücke, but opposed to Ofsiannikof, whose statement has just been given. Schultze found constantly, according to the period of the day, a varying proportion of small spherical red blood-corpuscles, the significance of which is not yet satisfactorily determined. In violent fevers there was a marked tendency in the red discs to become globular.—*Archiv. f. Microscop. Anatomie*, Band I.

#### ON THE EXISTENCE OF A PERIVASCULAR CANAL SYSTEM IN THE CENTRAL ORGANS OF THE NERVOUS SYSTEM, AND UPON ITS RELATIONS TO THE LYMPHATIC SYSTEM.

By W. HIS.

HE observes that on examining fine sections of the spinal cord from chromic-acid preparations, &c., it will be constantly found to present fissures which every one must have seen, and which have always been referred to breaking down of the tissue during section. But on attentive examination the fissures will be found to present smooth edges, and to be bordered by a layer of condensed tissue. Their course and division are regular, and the same for all sections made from the same cord. In the white substance they pursue for the most part a radial direction from the grey substance outwards, whilst others commencing at the periphery pass inwards; these are connected by smaller transverse fissures. In the grey substance they are less regularly arranged, are shorter and more angular and closer together, especially at the cervix cornu posterior. They recall the lymph fissures of the testicles and of the intestines. On dipping an injection-needle into a fresh calf's cord, and throwing in some injection, he was immediately successful in filling a canal system, whose arrangement on section exactly corresponded with that of the above-mentioned fissures. The grey substance appeared like a sponge, penetrated by a close network of tubes 1-100" to 4-1000" diam., and the same appearances were shown in the human cord. The radial direction was very well shown. The calibre of the chief branches diminishes quickly in passing outwards from the grey substance, but opens into a close and narrow network of canals. The whole closely resembles the root network of the lymphatic system; but we will first consider its relations to the blood-vessels.

Close examination shows that every fissure is traversed by one blood-vessel, sometimes lying close to the wall, sometimes free on both sides, and so, on transverse section, each vessel is surrounded by a clear space.\* Frommann, who has seen them, attributes these perivascular spaces to retraction of the tissues. The best mode of displaying them is to inject the blood-vessels in the usual way, and then to inject the spaces by sticking the needle in at random into the texture. The arrangement is also well shown by injecting a nitrate of silver solution either into the vessels or perivascular spaces. All modes of preparation show that the perivascular spaces are constant, and not produced by extravasation nor by collapse of the blood-vessels. The calibre of the spaces is two, three, or even four times greater than that of the contained vessel, and there is no bond of connection between the walls of the vessel and those of the circumscribing space.

Appearances similar to those described above are also to be seen in the brain. The spaces are proportionately larger round the larger vessels than around the smaller. His inquires, what relation does this canal system bear to the lymphatics?

Those accustomed to injections will readily perceive a similarity existing between the perivascular spaces and the lymphatics, and in their size and mode of branching, as well as in the absence of an investing membrane or wall separable from the

\* See also John Dean Smithsonian. "Contrib. to Knowl.," 1864, pl. v, vi, and viii.

adjoining tissues, and in the difficulty of exhibiting an epithelial lining. Fohmann and Arnold showed indisputably the presence of lymph-vessels in the pia mater, but no one has succeeded in tracing lymphatics into the substance of the brain. Are the perivascular spaces, then, continuous with the lymphatics of the pia mater?

In answer to this question His shows that the lymphatics of the pia mater can be injected from the perivascular spaces of the brain, and the union is effected by a wide lacunar system separating the brain from the pia mater. He believes there is no question that the perivascular spaces are the lymphatics of these parts of the nervous system. He thinks that, on the one hand, these perivascular spaces act as reservoirs for the nutritious fluids, and, on the other, serve as organs protecting these important parts from pressure, serving the same purpose for each individual segment of the nervous system that the liquor cerebro-spinalis does for the whole collectively.—*Siebold und Kölliker's Zeitschrift f. Wiss. Zool.*, xv., 1865, p. 127.

## RESEARCHES ON LYMPH AND BLOOD-VESSELS.

By LEOPOLD AUERBACH.

AUERBACH remarks that, according to the representations of all modern writers, besides the chyle spaces of the intestinal mucous and submucous tissue, there is a superficial subserous network of lymphatics; these communicate by some straight vessels, which traverse the longitudinal muscular coat obliquely. Whilst these statements hold for the frog and many cold-blooded animals, they are incorrect representations of what is really visible in warm-blooded animals.

There is, no doubt, a superficial subserous network of lymphatics; but this is only visible at the point of attachment of the mesentery, and over a space varying from half a millimètre to six millimètres on either side of it. On the remaining and by far the larger portion of the intestine there is no subperitoneal network. At and close to the attachment of the mesentery the vessels dip through the longitudinal muscular layer to communicate with the deeper stratum of lymphatics.

The elongated network of larger trunks, described by authors as subserous, is in reality situated between the longitudinal and circular layers of muscular fibres, and constitutes only the largest collecting trunks of a very much closer network of lymphatics situated at this level, which, again, is only an offset of a still larger system, that everywhere interpenetrates the muscular tissue, and is in connection with the chyle passages. These lymphatics of the muscular layers he has examined in the pig, calf, rabbit, guinea-pig, cat, and dog. He terms them *interfascicular* capillaries of the lymphatics. In the longitudinal muscular tissue there is usually only one layer of these capillaries, but in the circular layer of muscular tissue there are many layers succeeding to one another. They present the usual characters of lymphatics.

The lymphatics from both layers of the muscular coat pour their contents into a network of larger canals, which is extended between the muscular coats in the same fissure or space as that in which the plexus myentericus nervosus is found, and, indeed, always on the inner side of the latter, crossing its trunks and ganglia. This he terms the *interlamina* network, and states that it may be very easily shown. The tubes vary greatly in size, from 1·7 to 1·6 mm. in diameter, and the larger ones have valves, and, beginning small at the free border of the intestine, course more or less obliquely towards the attached border, with many dilatations and constrictions.

Chyle is often found in the *interlamina* network which constitutes a medium of communication between the chyle passages of the submucous tissue on the one hand, and with the canals of the mesentery which carry off the chyle on the other. Yet, however large and spacious the vessels of this network may be, they only carry off half the entire amount of chyle, the remainder being transmitted through the submucous vessels.

As regards the form and arrangement of the latter network of vessels, he has little to add to the investigations of Teichmann, His, and Frey. In the mucous membrane, as well as in the submucous tissue, he notes, however, that he has usually found the lymphatic vessels clearly *tubular*, with the exception of those which surround the base of the follicles.

In regard to the larger vessels which are formed from the *submucous* networks, they do not, as is frequently stated, perforate at certain points the muscular layers. They divide into two sets, of which one is his *interlamina* network; the other continues in the submucous tissue from the free to the attached border of the intestine, where it perforates the muscular tissues

to reach the serous coat and blends with the interlamina canals. The trunks so formed at once pass to the mesentery. It thus appears that there are two layers of lymphatic or rather chyle vessels, differently situated as regards the muscular tissues (which must have a certain physiological significance), one of them passing between the two muscular tissues and one in the submucous tissue.

As regards the finer structure of the lymphatics, he gives a good historical *resumé* of the different opinions that have been held on the question of the presence of a distinct membranous wall to the finer lymphatic capillaries, some admitting, some denying it, and maintaining that they are only splits or fissures in the tissue.

In his own observations on the finest capillaries of the lymphatics he could only see for a long time certain cell-nuclei present in great numbers, with a double contour and clear contents, a few fine granules, and one or two nucleoli. He then observed that these were not scattered irregularly, but followed certain lines, and by-and-by that they were adherent to a tubular membrane of perfect transparency, the borders only of which (when seen in profile) were visible. By carefully moving the slide cover he sometimes saw folds in this membrane. These appearances alike proved the great flexibility and independency of the membrane, and showed also that it was not invested by any other membrane. These vessels presented a most striking analogy to the capillary blood-vessels, but their great and varying diameter and the simple structure of their walls showed conclusively that they were not blood-vessels.

Now, whilst Recklinghausen had described in certain lymph-vessels an epithelial coat, the cells of which were destitute of nuclei, it suddenly struck Auerbach that the scattered nuclei above mentioned might be the nuclei of flat epithelial cells lying in close apposition to one another. Of such a layer, however, no trace was perceptible on simply examining fresh specimens; but he now proceeded to try Recklinghausen's plan of injecting a weak solution of nitrate of silver, and he undertook a fresh series of researches with this object, and on various accounts found the guinea-pig most satisfactory. He then discovered that there were, indeed, epithelial cells lining the tubes; in some the flat cells remained quite clear or presented only a few fine granules, whilst the *nuclei* presented a dark double contour line and distinct nucleoli. In other instances the *cells* remained clear close to their dark outline, but at a little distance a finely granular brown precipitate formed, becoming denser near centre of cell, and in this dark granular material the nuclei appeared only as a clear, sometimes very sharply limited, spot. Or lastly, according to the mode of preparation, he observed only a dark granular mass near the centre, apparently consisting of a kind of precipitate. The two last appearances were chiefly seen in the widest lymph spaces, and he considers that they prove that not the whole of these cells are cornified plates, but that in part, at least, they contain in their interior a softer material, more liable to chemical change, and which is chiefly collected around the nuclei. Sometimes two nuclei are seen in a cell. The sinuosity of the walls of the cells is a very remarkable character, and pretty constant, though it varies in degree; smooth and even borders occur only in the widest canals.

Thus, he believes the finest lymphatics are bounded by a layer of nucleated cells, adhering together and in close apposition. He thinks the lines indicating the outlines of the cells may be possibly due to the presence, as Recklinghausen maintains, of an intervening softer material, which takes the silver impregnation better than the cells, but that they more probably indicate the presence of small furrows between neighbouring cells in which the silver deposit accumulates. He alludes to two forms of stomata that have been noticed in the walls of the vessels, and denies both.

"In the intestinal walls the cells which have been described unite by their edges to form quite a firm membrane, which alone constitutes the wall of the lymphatics, and is not in any way composed or strengthened by the surrounding tissues or by any modification of them, and, in point of fact, is for the most part only loosely adherent to them."

The only exception to this is the tissue forming the substance of the villus which adheres to the walls of the enclosed chyle vessel.

THE cholera has again made its appearance at St. Petersburg, particularly in the village of Tzarskoe Selo, in the suburbs of that city.

A CHILD has been poisoned at the east end of London by eating mistletoe berries.

## Proceedings of Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

ANNUAL MEETING, DECEMBER 31ST, 1866.

T. B. PEACOCK, M.D., President, in the Chair.

#### REPORT OF COUNCIL.

THE subjoined is a copy of the report read at the annual meeting:—

“The session of the Pathological Society 1865-6 has been marked by the steady advance in prosperity and usefulness which the condition of the Society's affairs enabled the Council to predict in presenting their last report. It was stated in that report that the number of annual subscriptions which had been received in the past year (303) was the largest which the Society had ever yet attained. In the present annual account, however, the receipt of 314 annual subscriptions is acknowledged, as well as two composition fees from resident members. The number of fees by admissions has also risen from 27 to 35. Thus it is seen that the number of the Society's members continues steadily on the increase.

“Nor will it be denied by those who have taken part in the session which has just terminated, that the activity and exertions of the working members of the Society in the prosecution of the object for which it was founded, is in proportion to its growth in numbers and reputation. The large expenditure which the Council have sanctioned on the seventeenth annual volume is, they hope, justified by the production of a volume, not only much larger than its predecessors, but containing also a corresponding proportion of matter of permanent value and interest. It is, perhaps, a subject of regret that the expenses of a volume, which, like this, shall be worthy of the reputation of the Pathological Society, should so nearly exhaust all the disposable funds. The Council have on this account taken into renewed consideration the possibility of obtaining a place of meeting without the great expense to which they are put for the present rooms. They have accordingly drawn up and presented to the Board of Works a petition for admission into the rooms at Burlington House. As the accommodation which this Society requires can be afforded without displacing, or even inconveniencing, any of the bodies at present lodged at Burlington House, the Council entertain a sanguine hope that the request may be granted.

“The alterations in the rules for exhibiting living specimens, and the rule as to specimens which are not presented when called for in their turn, have been found to work well, and have, it is hoped, quite remedied the slight inconveniences which had been felt in former sessions; they have been printed on the yearly cards.

“Another topic which has lately been discussed in the Society and referred by them to the Council, is the appointment of a Committee to examine and report on all the specimens submitted to the Society as being examples of ‘Cancer.’ The pressure of the necessary annual business at this period of the session has prevented the Council from completing this matter, but they trust soon to be able to submit the names and regulations of this Committee for the approval of the Society.

“In conclusion, the Council beg to hand in the Treasurer's Report, of which the following is a summary:—

“The total income of the Society was £464 6s. 6d., and the total expenditure £518 19s. 8d., exclusive of £100 invested in the funds. The balance in hand at the commencement of the session was £122 19s. 11½d., of which £100 was thus invested, so that there is at present due to the Treasurer £31 13s. 2½d. The annual income is made up of the following items:—

Sale of Transactions	£24	1	11
Dividends—on the sum of £422 6s. 6d.; Stock			
—an increase of £113 15s. 2d.; Stock on the sum invested last year	10	15	7
Entrance and composition fees and subscriptions	429	9	0

“The last item shows a very great increase on any previous year.

“Thus it appears that the income of the Society, both from subscriptions and investments, is increasing, and although the expenditure this year has exceeded the income, it ought in fairness to be taken into account that the expenditure includes an item of £30 for the printing and binding of fifty copies of

volume xv., a volume which has a fair sale, and the printing of which may, therefore, be regarded as a remunerative investment. The large expenditure on vol. xvii., which has amounted to £339 6s. 6d., will also, it is believed, prove remunerative, for the Society now prints 500 copies instead of 450, and is, therefore, in a position, as far as the three last volumes are concerned, to meet the numerous demands which are constantly made for its publications. This being the case the Council see no reason for discouragement, though the balance of expenditure has for once been accidentally against the Society, and if they succeed in getting quit of the great charge for rooms, they will be enabled to devote a still greater proportion of the receipts to the legitimate purpose of improving the yearly volume.”

## Reviews.

CLINICAL HISTORIES; WITH COMMENTS. By HENRY DAY, M.D., Member of the Royal College of Physicians; Physician to the Stafford County Infirmary. London: Churchill and Sons. 1866. Pp. 254.

DR. DAY, in a very modest unassuming style, describes in his preface the plan and nature of his book. “I have made,” he observes, “every history rest upon an observed fact or facts of disease. I have tried to read those facts by the forward light of my time; and in some cases I have ventured to comment, as a practitioner purely, on points of difficulty or doubt. . . . The plan of the book is thus very simple, and very free from originality; but after all it is on the plan of the earlier steps in the history of our art, and it will probably last so long as the art lasts.” His volume consists of thirteen of these so-called “Histories,” embracing the following subjects:—Cerebro-Spinal Meningitis, a Rare Case of Ovarian Dropsy, on Secondary Cancer in the Lungs, on the Treatment of Acute Rheumatism by Blisters, Rheumatic Fever without Pain, Chorea from Spinal Irritation, Pelvic Hæmatocele, Epilepsy from Peripheral Irritation, Epilepsy from Hepatic Congestion, alternating Leucocythemia, Leucocythemia, Hysterical Facial Paralysis, and Cardiac Apnoea, formerly called Angina Pectoris. We shall briefly notice two of his “Histories,” those in which he discusses the treatment of Acute Rheumatism by Blisters, and Cardiac Apnoea. Nothing, as our author well observes, more thoroughly shows our uncertain knowledge regarding the true nature of rheumatism than the varieties of treatment recommended by different physicians of eminence. The alkaline treatment of Basham and others—the lime-juice treatment of Dr. G. O. Rees—the blood-letting treatment of the Paris school a quarter of a century ago—the blanketing system of Dr. T. K. Chambers—the blistering of Dr. Herbert Davies, and the mint-water treatment (obviously a new *placebo*) of Dr. Gill, are all alluded to; and Dr. Day, if he pleased, might have much enlarged his list of special (we can hardly say specific) remedies for this disease. Dr. Day's views regarding treatment are such as most sound physicians will endorse. He maintains that the treatment should never be left to nature alone; that medical treatment does not consist in the administration of drugs alone, and that we should not rely on any one remedy alone. Of the many remedies he has tried there is one which has never disappointed him “in affording marked and almost immediate relief from those agonising articular pains which, with very few exceptions, are found to be present in acute rheumatic fever, and that remedy is the blistering method of Dr. Herbert Davies.” The cases of acute rheumatism admitted into the Stafford Infirmary being numerous, he has been able to give the remedy a fair trial; and he narrates the particulars of six instances in which advantage was derived from this treatment. In none of his cases has he, however, trusted to blistering *alone*. “In almost every instance there was at some time or other during the attack, a *plain* and not to be mistaken indication for the administration of a cathartic or an aperient, a tonic or an alterative, a sedative or stimulant, but I by no means admit that the use of these or any such remedies detracts in any way from the merit that may, I consider, be fairly claimed for the relief obtained from severe pain, and the immunity secured from cardiac complications by the aid of the blister treatment.” Pp. 69, 70. It would have been satisfactory if we had been told how the blistering treatment produces its beneficial symptoms; but all that we learn from Dr. Day on this point is that no particular acid seems to be eliminated by means of the serum discharged, as the latter has always been found to be alkaline or neutral. May not certain lactates or other salts of organic

acids be present in the serum without producing an acid reaction? In concluding this "History" our author draws attention to the singular fact that blisters have the power of rapidly changing the reaction of the urine from a well-marked acid to a neutral or alkaline reaction.

Our limited space forbids us from doing more than briefly noticing the History treating of Cardiac Apnoea or Angina Pectoris. Two cases—one, that of a commercial traveller "addicted to beer," and the other, that of a sober dissenting miner, are very graphically described, and the volume concludes with a few pages abounding in sound practical reflections on the treatment of this terrible disease.

We have long known Dr. Day by reputation as one of our leading provincial physicians; we now congratulate him on his successful appearance as an author, and we trust that in the course of time we shall see a second series of "Histories" issue from his pen.

**LARDNER'S HANDBOOK OF NATURAL PHILOSOPHY.** Revised and edited by G. FOSTER, B.A., F.C.S. Walton and Maberly. London. 1866.

DR. LARDNER'S handbooks have become institutions. Written at a period when such works were scarce, they perhaps owe a great deal of their popularity not only to that cause, but also to a simplicity of construction and freedom from excessive minutiae, which are most desirable in a handbook on any practical science. Some of our contemporaries have expressed surprise that Mr. Foster should have devoted his energies to the reconstruction of a book which was certainly anything but a scientific perfection; but although we shall be very glad to welcome an offspring of Mr. Foster's own, we think his time has been well expended in the reconstruction of the present manual. He says in his advertisement that he has endeavoured to bring it into harmony with the best scientific teaching of the day, but has adhered as closely as possible, not only to the arrangement and general plan, but also to the phraseology of the last edition published in the author's lifetime. The result has been the production of a book sound in theory, and constructed upon a model that it would be difficult to replace.

The more important additions mentioned by the editor are in Book 1—A section on the phenomenon of the residual charge of the Leyden jar, and a chapter (xiv.) on sources of electricity other than friction. The principal additions to Book 2 relate to Ohm's laws of the intensity of currents, the tangent galvanometer, the measurement of conducting powers, the rheostat, ozone, the polarization of electrodes, the retardation of telegraphic signals by inductive action in submarine cables, and the laws of the development of heat in the Voltaic circuit. In the same way numerous additions to acoustics.

But the editor of the present edition has done much more than he has here written himself down. The brackets, marking new matter, very frequently appear, and the matter contained in each is generally of the utmost importance, as evinced at page 3, on the nature of electricity and the mode of describing electrical effects and the hypothesis of electrical fluids. Also, the editor's remarks on the chemical theory of a Daniell's cell, page 111, &c.

We think it is a very desirable practice for publishers to bring out old-established works on science, if brought up to the requirements of the times by an able man. But equally to be condemned is the practice of publishers advertising works which are stale and unprofitable. We presume they must find purchasers for such manuals, which are, however, comparatively useless in this progressive age.

**TAPEWORMS (Human Entozoa): their Sources, Nature, and Treatment.** By T. SPENCER COBBOLD, M.D., F.R.S. Pp. 83. London: Longmans. 1866.

This small and useful volume is devoted to the consideration of only one great group of the parasites which inhabit the human body, the whole subject being treated at great length in the author's larger work on "Entozoa." The tapeworms, however, include a considerable number of species, and even different genera, and the distinguishing marks which separate them have been elucidated in several instances by Dr. Cobbold's labours. Thus it is generally supposed that the common tapeworm found in the human subject belongs to a single species—the *tenia solium*; but Dr. Cobbold has very clearly shown that there are two distinct forms of tapeworms—namely, the *tenia solium* and the *tenia mediocanellata*, and he has further shown that the one is introduced by eating pork, and the other by eating beef and veal, and that the latter is the more common

of the two. Besides these, Dr. Cobbold describes the elliptical tapeworm and the margined tapeworm (*t. elliptica* and *t. marginata*), the spotted, the ridged, the Egyptian tapeworm; besides the pit-headed or broad, and the Greenland tapeworms, which belong to the genus *bothriocephalus*. The researches of modern helminthologists, among whom Dr. Cobbold holds a justly distinguished place, have not been mere matters of dry technical disquisitions, but they have thrown great light upon the origin of these parasites, and have thus indicated the methods to be adopted in preventing their introduction into the human system. In the little work before us, not only are the origin, development, and specific peculiarities of the tapeworms discussed, but the treatment is fully described, and the author insists, and perhaps not without reason, that the drugs employed for the destruction and expulsion of the parasites should be pure and freshly prepared. Among the various taniacides, Dr. Cobbold gives the preference to the root of the male fern, administered in the form of the ethereal extract.

## CURRENT LITERATURE.

PUNCTUAL to date, the fifty-fourth volume of Braithwaite's *Retrospect of Medicine*, for the second half of the year 1866, reached us by the 1st of January. Old subscribers will find this volume quite equal to its predecessors. Woodcuts of new instruments are introduced where necessary, among which we notice Mr. Sheraton's steel fillet, and an ingenious stricture dilator on the screw principle, invented by Dr. Aspray. Another interesting feature of *Braithwaite* is the SYNOPSIS, of about forty pages, containing a brief abstract of the most practical articles in the volume, arranged alphabetically.

We have also received the new volume of the *Half-yearly Abstract of the Medical Sciences*. This volume contains, in addition to the practical digest of the periodicals, reviews and bibliographical notices; and in an appendix the editors have furnished a translation of the valuable *Rules for the Guidance of Sanitary Authorities, Practitioners, and the Public, during Epidemic Cholera*, drawn up by Professors Griesinger, Pettenkofer, and Wunderlich.

The new number of the *Westminster Review*, in its account of contemporary literature, notices a number of medical and scientific works, thus furnishing an additional attraction to those of our profession who support this able quarterly. We refrain from further details respecting a work the character of which is so well known, merely saying that the present number maintains the usual high standard.

Of other journals lately received we may name the *Popular Science Review* and *Science Gossip*.

Dr. Forbes Winslow has published, in the form of a pamphlet, the views on *Uncontrollable Drunkenness* (Hardwicke) which he lately so eloquently advocated in the *Pall-Mall Gazette*. We commend Dr. Winslow's statement as a judicious summary of the arguments in favour of properly supervised sanatoria for drunkards.

A small work on *Saline Venous Injections in Cholera*, by G. F. Girdwood, M.D., who tried the plan in 1832, and advocates it as especially valuable, because it can do no harm, we have handed to the writer of our Special Report on the subject.

For Mr. Christopher Heath's pamphlet, *On the Endoscope as a Means for the Diagnosis and Treatment of Urethral Disease* (J. Churchill and Sons), we have no commendation. As a contribution to a contemporary it might pass muster; but on reprinting it in pamphlet form, the author claims for it a position to which it is not entitled. It is a mere hash of what has been previously done, and better done too, by others. True—to his pages of description, which might well be en-

titled *after Cruise*, Mr. Heath adds cases examined by him, but in which nothing was found that a first year's student could not describe on his first attempt. Desormeaux and Cruise have both done good service. If Mr. Heath thinks to snatch their laurels, and connect his own name with the endoscope by means of so useless a pamphlet as the present, we can assure him he is altogether mistaken. Let him add something material to our stock of knowledge, and we shall be happy to welcome him in this or any other field; but to dish up the contributions of others is unworthy of his position as a teacher.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 16, 1867.

### INFANTICIDE.

AMONG the social questions of the day that of Infanticide is very properly, at the present moment, engaging much of the attention of the community, and the Harveian Society of London has done a good work in appointing a Committee for investigating the whole subject, with a view of revising the laws now in operation in reference to this very prevalent crime. This Committee has collected a great amount of information, and has spent much time in deliberation, and the result has been a report which will very soon be presented to the profession and to the public through the medium of the press.

It is quite evident that the aspect in which Infanticide presents itself in general to the public mind discloses only a very small part of the gigantic evil, of which the proceedings in our courts of law exhibit the superficial results. A poor miserable female, broken down in health and dejected in mind, is dragged as a prisoner at the bar of a criminal court, charged with the crime of wilful murder, the victim being her own infant, whose life all the instincts of human nature should instigate her to preserve. Formal evidence is given of the death of the child, and of its life having been terminated by other than natural means, and of the recent delivery of the mother; but notwithstanding the weight of the evidence, the prisoner is generally acquitted on some technical objection, or on the suggestion of some doubtful point in physiology; or if a conviction is obtained, the capital sentence, which would necessarily follow in other cases, is hardly ever, and, we might say, never carried into effect. Indeed, the spectacle of a wretched woman being dragged to the gallows for such an offence would in all probability so outrage the public mind that in any subsequent case no conviction would ever take place at all, and the law upon the subject would be practically a dead letter. Again, for one woman who is thus brought before the legal tribunals for the murder of her infant, how

many are there who entirely escape, and whose crime is suspected by none, the murdered offspring having been so successfully removed by the ingenuity of the mother or her accomplices that the relationship between the victim and the murderess remains for ever concealed?

But, rare as the convictions are for the crime of Infanticide, and comparatively light as the punishment is which is inflicted upon the guilty party, there can be no question that the crime itself is widely prevalent in the present day, and that it constitutes a dark blot upon our boasted civilization. One great difficulty in dealing with the offence arises from the fact that, although the female alone appears at the bar of justice, there is always necessarily another human being who must have been a participator, at least to a certain extent, in her guilt. The man in such cases, although he may have been originally equally, or more guilty than the woman, entirely escapes; while the poor unfortunate woman endures the pain, the misery, the shame, the exposure, and the risk of punishment. Hence arises the social question, which the world has been too long content to ignore, as to the measures of repression which the laws or the customs of the age ought to institute with a view of equalising the penalties between the two sexes, in reference to a fault of which they are at least jointly guilty, or as to the provision which ought to be made for the maintenance and support of the offspring of such illicit unions.

To these questions the attention of the Committee of the Harveian Society has been specially directed, and they have thoroughly investigated the laws relating to the care of illegitimate children, and to the punishment of Infanticide. They have come to the conclusion that Foundling Hospitals, if established on such a scale as to be efficient, would only encourage the evils which they are intended to obviate, and that an increase of infant mortality, to say nothing of other injurious consequences, would result from the reception of a large number of children into such institutions. The present system of affiliation, which requires the woman to bring corroborative proof in all cases as to the paternity of the infant, and which affixes so small a sum as half-a-crown a week as the remuneration upon the reputed father for the support of the child, is also very strongly condemned; and it is suggested that more facilities should be allowed to the woman to prove her case, and that under the existing rate of the cost of provisions, a larger weekly sum should be accorded to her. The punishment of Infanticide, unless of course in very aggravated cases, should fall short of the extreme penalty of the law, and should be reduced to that of murder in the second degree, in accordance with a late recommendation of the Commissioners on Capital Punishment.

It would, of course, be easy to dispute the efficacy of some of the proposals made by the Committee, and, with all due sympathy for the weaker sex in their sorrows and sufferings, it must not be forgotten that many women, for purposes of revenge or jealousy, or gain, might, and do, involve innocent men; but, on the other hand, it cannot be denied that the present laws press with undue severity on the woman, and that they loudly call for revision. The Committee of the Harveian Society deserve the warmest thanks for their meritorious labours, which we cannot but believe will have the effect of impressing our legislators with the magnitude of the existing evils, and with the necessity of introducing measures for their redress.

## THEORIES OF CHOLERA.

### II.

WE have before us a valuable pamphlet, entitled *Thoughts on the Present Theories of the Algide Stage of Cholera*, by John Cockle, M.D., Physician to the Royal Free Hospital. The subject is so ably treated that we almost regret not having the opportunity of reproducing the whole twenty-four pages into which Dr. Cockle has condensed his views. As, however, space forbids this, and, we may add, justice to the author, we propose to lay before our readers as full an abstract as we can. Two theories are examined by Dr. Cockle—one that a “poison is breathed into the lungs,” and seeks “elimination through the gastro-intestinal tract;” the other that the poison finds access through this tract, whence it spreads its influence over “both nervous and circulating systems.” The first theory adopted by Dr. Johnson is first examined. Dr. Cockle considers that, if this “theory be correct, the elimination act is a necessary consequence;” and he then proceeds to examine the theory in its several parts, arriving at the conclusion that it does not adequately explain the phenomena of the disease, nor yield successful results when put to the test of practice.

The objections to the theory are thus summed up by Dr. Cockle:—

“The alleged spasm is rather a matter of inference than of actual demonstration. The phenomena supposed to depend thereon may admit of a different explanation. It is unquestionably shown by morbid anatomy that black blood is occasionally found in the left ventricle, and sometimes in considerable quantity in the upper portion of the aorta. Its presence with such character appears to be totally irreconcilable with any hypothesis of simple spasm. If the spasm were even assumed at times as clonic, to relax its grip, the blood (unless the poison possessed the power to change its colour, which is without a shadow of proof) must be oxygenated, for, as a rule, the air traverses freely the remotest cells. It is also opposed by the experiments of Majendie, who, though noting the rare occurrence of almost perfect vacuity of an artery, was nevertheless most firmly convinced that the blood traversed the pulmonary capillaries even in the most exquisitely-typed instances of algide condition,\* and who illustrated the proposition by exhibiting the black blood, just abstracted, to his hearers, as also by the injection of ether and dissolved camphor into the veins and bowels and detecting the vapour in the expired air.

“Moreover, were the theory correct, no sooner had the incubation stage expired and the actual invasion period set in, the agent having for its essence the production of spasm of the pulmonary arteries, such spasm should correspond with the in-

vasion, and algide phenomena precede, at least coincide, with transudation into the intestines, and decrease in proportion to the eliminative discharge. Is this sequence in accordance with ordinary observation?

“Again, if it be a characteristic of cholera poison to induce spasm of the pulmonary arterioles and of those of the muscular tissue (?), causing the severe cramps, why do the intestinal capillaries evade the law? We can quite readily understand the action of an agent upon a given organ, or system of organs, e.g., opium upon a certain portion of the brain, strychnine upon the spinal chord, emetin on the stomach, and so forth; but we can hardly understand an agent though for a purpose of elimination, blowing, as it were, hot and cold with the same breath, as for example, strychnine contracting one set of muscles and relaxing another. Agonising cramps are certainly not the exclusive monopoly of epidemic cholera poison, for nothing surely could exceed the violence of those mentioned by Sydenham in the bad sporadic cholera of 1676, the patient jumping out of bed frantic with pain, with a pulse scarcely perceptible.† Death often occurred in twenty-four hours.

“Next, with respect to the influence of warm saline injections into the veins. The instantaneity of their action shows that the pulmonary circulation must be free. But, as to the explanation of this indisputable fact? Is it in accordance with Dr. Johnson’s views that their temperature relaxes spasm, or may it be that their restored liquidity of the blood again affords the condition of its motion, it is, I cannot but imagine, making a large demand on our belief to require the admission that warm venous injections should so quickly cause a spasm to unloose its hold that had obstinately resisted the opium, stramonium, valerian, ether, inhalation of hot vapour (Piorry) of ether, so often and so vainly tried! Saline injections by the time they reached the heart could scarcely possess a temperature very much higher than that actually existing in the right chambers, why then should they be more efficacious in a mere point of temperature than the warm blood therein, were not this blood vitally and physically changed and stagnant by the privation of that intercellular fluid which we are taught by physiology imparts the requisite glibness to its movement, and without which arrested movement would be the inevitable result. This want of motion may be increased by the tendency of the augmented number of white corpuscles, mentioned by Virchow, Reinhardt, and Leubuscher, to adhere to the vascular walls. In fine, saline injections afford for a time pabulum and restore the equilibrium of fluid pressure; they fail, however, in maintaining the vital machinery permanently in action, partly because they again transude, but principally because they fail in what the blood demands, the restoration of its proteine elements.‡

“Lastly, we must look at the theory of spasm as tested by the existence of dyspnoea. If the minute branches of the pulmonary artery were closed by spasm, dyspnoea should scarcely ever be absent; indeed, it should be a very prominent symptom in the algide stage; that it is not so in many cases I can most confidently assert. The observations made by Mr. Hill and myself at the Royal Free Hospital, and by me at the East End of London I can truthfully say have been too carefully made to overlook this important point.‡ I admit the difficulty holds on any theory, still the fact remains and must be explained by some condition of innervation.§ The percussion of the cardiac region also yields no evidence of distended right

\* In the epidemic of Berlin, 1848, a precisely similar instance is recorded by Schütz. Virchow, *Archiv*.

† In connection with the question of venous injection, it may be excusable to state that I have paid much attention to this subject, and was, unless I mistake, the first in this country to propose transfusion of blood in some of the blood poisons (*Essay on the Poison of the Cobra di Capello*, Highley, 1852). A week or two since a letter on this subject in connection with cholera was sent to the editor of the *British Medical Journal*, Nov. 10, who did me the favour to insert it. Since then, I have again looked over the results obtained by Dieffenbach from transfusion in cholera, and fancy I discover the cause of his failure. It now occurs to me that the way to insure the success of the plan is, first to employ the saline injection, and when the circulation is restored, by giving to the blood discs their normal liquidity, then to transfuse blood under the condition insisted on by Panum. The action even of saline injection surely points out the path to follow, no other remedy in the algide stage of cholera for one moment approaches them in their magically resuscitative power.

‡ The observations of Reinhardt and Leubuscher, *Epidemic of 1848*, fully confirm this statement. “Bei vielen Kranken blieb indess die Respiration bis zum Tode ein ruhig.” Virchow, *Archiv*, s. 440, II. Band, 1849.

§ Ainsi donc si la respiration des cholériques est altérée, ce n’est pas par obstacle physique au cours de san le gâ traverspoumon. Majendie, p. 115.

\* La continuation de la circulation à travers le tissu, pulmonaire est un point capital relatif à l’histoire de la respiration des cholériques. — *Leçons, etc.*, p. 104

chambers.\* The left ventricle evidently beats to the last; and although the sounds are dull and toneless, resembling those produced by Dr. Halford on closing the pulmonary veins for a short time, still some blood must pass as we have already seen. Occasionally the cardiac sounds are attended with bruit from the obstruction offered by the thick and clotting blood. "The phenomena of intermittent cholera and of the occasionally observed lung cholera are as inexplicable on this as any other hypothesis."

The second theory next occupies Dr. Cockle's attention. Carefully comparing with cholera other affections of the gastro-intestinal tract, and especially such as have any resemblance to that disease; and, considering the "general facts connected with the action of poisons," he gives in his adhesion to this theory, although admitting that the analysis of its pathology which he offers is "very far from perfect."

As, after all, treatment must be the touchstone of theories, we cannot do better than quote the conclusions to which Dr. Cockle arrives, commending as we heartily do the whole pamphlet to the earnest attention of our readers:

"The circle of inquiry," he says, "appears now so much narrowed that we must hope these difficulties are not invincible, and that ere long we may be rewarded with a pathology sufficiently comprehensive to warrant a more uniform plan of treatment than at present exists; for it is certain that one or other theory must be radically wrong, and consequently, in its application, proportionately destructive. In our present painful transition stage of treatment, each practitioner must, from the conflict of views,† trust to his judgment in the individual case.

"That cases may do well without our aid we sometimes see, for cholera has its *plus* and *minus* forms. But, face to face with the disease in its more serious shape, eye witnesses of the telling influence of the oft frightful drain, does it impress us as nature's act to cure, or carry with it one character of safety? do patients tell us at each escape of fluid they feel relieved or have their strength increased? for such are the results that should attend eliminative or critical discharge.‡ If they do their looks belie them strangely. In such a state, no matter how we regard the disease, fever or flux, irritation or poison—no matter how we treat it—calomel to restore the bile, salines to moderate the congestion, or opium and astringents to repress—again and again we seize the symptomatic indication, and try our best, each in his way, to stop that vomiting and purging, alike the symptoms and the danger of epidemic cholera.§ Is this mere routine, or the settled conviction of reasoned experience? If we are wrong, we have at least for our consolation the example of our betters; take that of the late Dr. Graves, a physician of more than ordinary fame, or look abroad, and search opinion there; and in the face of such teaching it must, indeed, require overwhelming evidence in favour of an opposite procedure; for the experience of able men, when theories clash, must be the fitting and the only guide.

\* Die starke Füllung des rechten Hertzens scheint während des Lebens noch nicht vorhanden zu sein; die Percussion ergibt (constant) einen Kleinen Umfang des Hertzens. Greisinger. Virchow, *Handbuch*, B. II., s. 326.

† Compare, for example, the theory of Dr. Johnson with the views this week put forth by a physician apparently of much experience in cholera, Dr. Beamish.—*Medical Press and Circular*, Nov. 13.

‡ Is the discharge eliminative, and if so, what is eliminated by the drain? Nothing that the most refined chemistry or microscopy can detect, nothing that seems directly infectious, but only becoming so from decomposition. Arguing from analogy, the elimination that removes a poison from the blood generally happens in the febrile or reactive stage, the visible evidence of Nature's power to struggle with her oppressor. "Nature," says Sydenham, "being by this means irritated, raises a fermentation in order to expel the enemy with less difficulty, this being the common instrument she uses to free the blood of its morbid particles, as well in fevers as in some other acute diseases." There are other affections caused by some poison in the system, as ague, erysipelas, and others, in which we do not trust to any elimination, but having tolerably certain remedies at hand, stop the disease yet nascent, not only without injury, but really with the prevention of injury. In the latter disease, we try to arrest even the elimination by covering the cutaneous patches with iron solution.

§ Unless some singular error prevails, the arrestive treatment yields by far the best results. According to Boudin, *Traité de Geograp. et Statistic. Médicales*, p. 366, 1857, the mean mortality is thus stated:—

Evacuant treatment	...	...	71.7	in 100
Stimulating "	...	...	54	"
Alterative "	...	...	36	"
Astringent "	...	...	20	"

One closing argument in favour of the arrestive plan may be drawn from the state of the epithelial lining of the gastro-intestinal tract; the longer the drain the greater the destruction, and the more tedious and intractable its repair.

## Notes on Current Topics.

**STREET REFORM.**—We have to announce the formation of a "Street Reform Society" in London. Verily, it is time something were done, for the streets of London have long been a disgrace to the commercial metropolis of the world. Considering the demands of its population, we have no hesitation in stigmatising the state of the London streets as worse than that of most of the second-rate capitals of Europe. In the minds of many who confide exclusively in the narratives of discontented travellers, Rome has long occupied the pre-eminence for dirty streets; yet with all its boasted wealth and progress, we could point out localities in London which we defy any one to parallel in the Eternal City, while the main thoroughfares of Rome, considering the state of her exchequer, compare favourably with those of London, and so far reflect credit on the Roman municipal authorities. The Street Reform Association will, we doubt not, meet with wide support.

**SIR JAMES Y. SIMPSON.**—It is not without gratification that we are able to report that this esteemed and learned Professor has so far recovered his health as to be able to resume his invaluable instruction at the University of Edinburgh. During Sir James Simpson's illness his duties have been performed for him by Dr. Keiller; but notwithstanding this gentleman's able labours, the pupils could not do otherwise than welcome back with enthusiasm their renowned clinical teacher. Sir J. Simpson has recommenced his instruction with a Course of Lectures on Anæsthesia, with which his name will remain indissolubly associated.

**THE GOVERNMENT OF LONDON.**—A deputation from an Association for the Better Local Government of the Metropolis has been received by Mr. Secretary Walpole. The right hon. gentleman acknowledged that the local government could be improved, and promised to lay the matter before his colleagues. The association proposes to create ten municipalities for the metropolis, a system which may obtain support from the really superior manner in which such matters are carried out on the Continent. A better time could scarcely have been chosen to press the subject on the attention of Government than immediately after the most signal failure of the existing authorities to cope with the late snow storm. Few arguments could be so convincing that a change could scarcely be for the worse than the fact that for three whole days London was reduced to the state of a country village, and locomotion, except on the good old-fashioned plan of "on the ten toes," was during that period almost impossible—the underground railway alone reaping the benefit of this sudden stoppage of omnibuses, cabs, and other vehicles.

**EVICTED TENANTS IN LONDON.**—The progress of great public works has deprived so many poor people of their homes, and consequently caused so much overcrowding, that an association has been formed to aid them. A deputation from this Society has already been received by Lord

Derby, who declared it was not a question of party, and assured the deputation that if the Government could see their way to a practical measure they would be happy to introduce it. There are undoubtedly many economic difficulties, which the political journals will not be slow to discuss. As medical men we are concerned at the great increase of overcrowding that has undoubtedly taken place, and should heartily rejoice in any just measure which would avert it in future. It was stated by one speaker that 50,000 of our working classes had been dispossessed in the last four years; but, he added, that during the same period 10,000 such persons had been provided with improved dwellings by philanthropic efforts. One-fifth of the evil has therefore, according to this statement, been remedied. We may add that a large number of workmen now live at considerable distances from their work, and travel by the underground railway as regularly as the middle classes. It may, therefore, be hoped that things are gradually improving again, the height of the speculation fever being over. Remembering, too, that there is a fair prospect of large returns for capital laid out in dwellings for the working men, we are not without hope that, before Parliament is likely to interfere, a good sum of money will have been invested in this manner.

**THE BRITISH PHARMACOPEIA.**—We are promised a new edition of this national work almost immediately. We trust that it may be found to be a considerable improvement upon its predecessor, and from the delay that has taken place in issuing it, we may presume that this will be the case. Perhaps it would have been more just towards the purchasers of the old edition to have published a separate appendix containing the changes authorized. So important, however, is the possession of one standard authority for the three kingdoms, that possibly the murmurs of dissatisfied purchasers may be drowned in the applause of those who find the work equal to their anticipations. We certainly do feel, however, that the price of the "Pharmacopœia" has hitherto been much too high. A work imposed upon a large class of purchasers ought certainly to be sold for the price of printing, paper, and binding. It is not the practice of the Government to net large profits on blue books, nor should the Medical Council on their "Pharmacopœia." A good deal of information respecting the contents of the forthcoming work has transpired in various quarters. We do not propose to repeat it, nor to hazard a series of guesses on the subject, still less shall we descend to picking up notes of conversations with those who are behind the scenes. The work has been deliberately carried on in the dark, very little has been allowed to ooze out of the intentions of those entrusted with it, and we should esteem ourselves unworthy of our position as professional journalists did we attempt to entrap any one into giving us premature and imperfect scraps of unauthorized information.

**POOR-LAW HOSPITALS FOR CONTAGIOUS DISEASES.**—It is reported that the Poor-law Board are not unlikely to erect two or three hospitals for the accommodation of London paupers labouring under contagious diseases, including fever. Such a step would probably prove of considerable service, and it has been suggested that for the Northern Districts the existing "Fever Hospital" at Islington might be purchased. In the east we do not see why the temporary cholera hospitals, so serviceable in the epidemic of last

summer, might not be utilized. They could be opened at once, and thus serve all the time during the building of more suitable hospitals. This would also enable the Poor-law Board to aid in the emergency of another outbreak of cholera, should we be so unfortunate as to have a recurrence of the disease next summer.

This, also, presents an opportunity of arranging a good working staff. To each of these hospitals we should be glad to see two or three physicians attached, as well as a resident and visiting medical officer. It would be positively wrong to suffer the knowledge obtainable at such hospitals to run to waste for want of trained men, competent to gather it, while to impose the medical charge of such an hospital on the ordinary parish doctor would be an unjust addition to his already too heavy duties, inasmuch as he could not, whatever his energies, do justice to both hospital and district; it would also constitute a positive cruelty to the paupers.

**CHOLERA AT CARNARVON.**—In consequence of the outbreak at Carnarvon, Dr. Seaton was sent by the Privy Council to inspect and report upon the state of the town. He found nothing new, and has only to repeat the old tale of dirt and carelessness of every kind. He reports that "there exists everything to invite and give intensity to an outbreak of cholera, or any other infectious or epidemic disease; great overcrowding and bad house construction, bad water supply, bad drainage, absence of privy accommodation, and accumulation of surface nuisances." It is useless to quote further. Dr. Seaton supports each of his statements with an array of facts that we commend to the attention, first of all, of those in authority at Carnarvon, and then to all those who doubt the power of dirt to produce disease. What matters the exact proportion of fatal cases to recoveries in a people surrounded by such an accumulation of filth. That any have escaped is evidently not due to the sanitary precautions of the Carnarvon authorities.

**SCURVY.**—Mr. Harry Leach, Resident Medical Officer to the *Dreadnought* Hospital Ship, communicates to the *Times* that 101 cases of scurvy were received on board during the past year, and that of these only five cases were brought from foreign ships. Here, then, is statistical proof of some sad deficiency in the British Mercantile Marine, which loudly calls for legislative interference. The English sailor droops under an easily preventible disease, while the ship-owners declare that there is no need for any change. In the name of humanity we protest against all this needless suffering. We repeat the shocking figures, 101 cases of preventible disease, admitted to one hospital ship on the Thames in 1866, and out of these 101 only five from foreign ships. We ask philanthropists to reflect on the statistics. We call upon the Legislature to prevent the continuance of this cruelty.

**THE NAVAL MEDICAL SERVICE.**—The Medical Service of the Navy being at a very low ebb at the present time, it appears that the Admiralty have come to the resolution of tempting medical candidates by offering a bounty to medical students. It is proposed, we understand, to offer the sum of two pounds a week to students who have completed their third year of medical study, and to continue that payment until the completion of the curriculum, when the candidates will each be required, under a personal bond (into which they must have entered in the first instance),

and two sureties, to join the service of the navy. In case of want of success, however, in passing the necessary examinations, the candidate and his sureties will be called upon to refund to the authorities the money which has been advanced. This scheme has not yet been promulgated, and we are very doubtful as to its success.

**SEASONABLE ACCIDENTS.**—During the few days of frost and snow, on account of the numerous accidents caused by the slippery state of the roads, falls in skating, &c., which occurred in private practice, we often heard it remarked that inquiry at the hospitals would show a great increase in the cases admitted during those days. It appears, however, that such is not the case, an absolute diminution in the number of accidents admitted having been noticed. At Guy's, St. Mary's, King's College, St. George's, and the London Hospitals, there were specimens of frost-bite to be seen. At St. Bartholomew's and University College cases of fracture of the patella were admitted. At most of the hospitals there were other fractures, bruises, and concussions caused by falls. At the Middlesex a case of Potts' fracture in an elderly man. Some accidents have also been reported in the newspapers as occurring to men engaged in clearing the roofs of houses of the snow. These men have fallen through skylights or trap-doors, and, in some instances, have severely injured themselves; yet, on the whole, as already stated, the cases of accident admitted to the London hospitals during the frost were much below the average. The result is probably due to the fact that no vehicles were in the streets, and few men at work in many dangerous occupations, such as building, or other work on scaffolding and ladders.

**INFRINGEMENT OF THE LUNACY LAWS.**—It cannot be too widely known that the Commissioners in Lunacy are compelled to take proceedings against any one transgressing *inadvertently* the laws for the protection of lunatics. Nor is this at all to be regretted. It is a very easy matter for any one in doubt to take the obvious precaution of inquiry, and it is necessary, for the sake of the sufferers, that their rights should be most strictly maintained. Let it be thoroughly understood that a medical man cannot legally receive a lunatic boarder without the proper certificates required by the Act. Mr. Nayler, of George-street, has recently been put to much inconvenience from an inadvertence of this kind. He has been summoned before the Central Criminal Court, and there required to enter into his own recognizance for the sum of £100 not to repeat the offence. We congratulate Mr. Nayler on his escaping thus easily, annoying as even this must have been to him; but, in spite of the high testimony to his character produced, and which partly tended to this conclusion, we cannot deny that the Commissioners have only done their duty.

### THE PUBLIC HEALTH.

(From the Registrar-General's Weekly Return.)

THE deaths registered in London during the week ending January 5 were 1437. It was the first week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1615. The deaths registered in the week were thus 178 below the average. The effects of the weather will, we may expect, be visible in the returns of next week, as registration and funerals were alike more or less retarded by the severe frost and the great snow-storm.

43 deaths from small-pox, 36 from measles, 35 from scarlatina, 54 from whooping-cough, 44 from typhus, and 16 from

diarrhoea were registered during the week. No death by cholera was recorded.

A labourer, aged 45 years, died in Fenchurch-street, city, on the 2nd of January, from "want of food, accelerated by cold."

The deaths of 17 infants, who were accidentally suffocated in bed, were registered in the week; the ages of these children varied from three weeks to six months. Five of them were killed on the 26th of December, three on the 27th of December, and two on the 1st of January. The deaths of six children from burns or scalds were also recorded. After festive nights parents cannot take too much care of their children.

The annual rate of mortality last week was 24 per 1000 in London, 31 in Edinburgh, and 25 in Dublin; 24 in Bristol, 24 in Birmingham, 35 in Liverpool, 31 in Manchester, 29 in Salford, 22 in Sheffield, 30 in Leeds, 28 in Hull, 44 in Newcastle-upon-Tyne, and 33 in Glasgow. The rate in Vienna was 31 per 1000 during the week ending the 22nd ult., when the mean temperature was 16.7 deg. Fahrenheit lower than in the same week in London, where the rate was 23 per 1000.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.408 in. The barometrical reading increased from 28.91 in. on Wednesday to 29.92 in. on Saturday. The mean temperature of the air in the week was 25.2 deg., which is 11.75 deg. below the average of the same week in fifty years (as determined by Mr. Glaisher). The highest day temperature was 41.9 deg., on Sunday. The lowest night temperature was 6.6 deg., on Saturday. On Friday the lowest temperature was 7.7 deg. The entire range of temperature in the week was 35.3 deg. On every day of the week the mean temperature was below the average, and the defect on Friday was no less than 23.2 deg. The mean of the highest temperatures of the water of the Thames was 39.3 deg.; that of the lowest was 36.3 deg. The difference between the mean dew-point temperature and the air temperature was 3.4 deg. Snow fell on Wednesday to the depth of about ten inches. The direction of the wind was variable. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the Southern outfall works, Crossness, was 180,230 cubic metres.\*

### THE YEAR 1866.

The great cities of the kingdom may be thus arranged according to their rates of mortality during the past year. To 1000 persons living, the deaths in Birmingham were 24, Hull 24, Bristol 25, Edinburgh 27, Sheffield 28, Dublin 28, Salford 29, Glasgow 30, Manchester 32, Newcastle-on-Tyne 32, Leeds 33, Liverpool 42. The mortality was lower than it was in the year 1865 in Manchester, Salford, Birmingham, Hull, Edinburgh, Glasgow; and higher in Leeds, Bristol, Dublin, and Liverpool. Cholera was excessively fatal in Liverpool.

In London the mortality was at the annual rate of 26, which is two above the average, entirely due to cholera, happily confined within narrow limits. The mortality of London, west, north, central, and south, holding 2,430,046 people, was 24½, or slightly above the average, while in the east districts the rate was 34 in 1000 among 606,945 inhabitants. The causes of this local intensity have already been explained. Cholera was epidemic, and proved extraordinarily fatal for a short time, from causes that favoured the diffusion of its elements. The detection of these causes, and the judicious hygienic measures which were employed, generally stopped its progress, and saved, as well as much suffering, many thousands of lives.

### MEDICAL TRIAL.

CENTRAL CRIMINAL COURT, JANUARY 9TH.

OFFENCE AGAINST THE LUNACY LAWS.

MR. GEORGE NAYLER, surgeon, living at George-street, Hanover-square, was indicted for having unlawfully received and boarded, at a certain house in Hanwell, not being an hospital registered according to the Act of Parliament, a certain patient as a lunatic, without a proper order of medical certificate as required by the Act.

The defendant pleaded guilty.

\* A cubic metre is equal in volume to 35.3174 cubic feet, or to 220.0967 imperial gallons. It is nearly equivalent to the old English "tun" of four hogsheds, holding 35.248 cubic feet. It is in general use on the Continent, and is a much better unit for measuring sewage or water supply than the gallon.

Mr. Metcalf (with whom was Mr. Beasley), instructed by the Commissioners in Lunacy, informed the Court that the defendant had transgressed the law by receiving into his house at Hanwell the son of a clergyman, at the charge of £130 per year without the proper order.

Mr. Poland addressed the Common Serjeant for the defendant, and called Dr. Jenner, Physician in Ordinary to the Queen; Mr. Pollock, Surgeon to his Royal Highness the Prince of Wales; and Mr. Holmes, surgeon, who gave the defendant the highest possible character both for his professional ability and as a gentleman. They severally expressed their belief that he was a person who was incapable of a dishonourable action.

The Common Serjeant said that it was a very proper matter for the Commissioners to take up, and he considered that in thus bringing it forward they had done that which was sufficient. It would be his pleasing duty to allow the case to stop here upon the defendant entering into his recognisance for £100. He was sure that there would be no fresh cause of complaint against the defendant.

## Correspondence.

### THE LANCET'S LATEST AND GREATEST DISCOVERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—All modern medical teaching has been thrown into the shade by the astounding information in one of your contemporaries that "the radiation of yellow fever from St. Thomas to the English coast has not ceased." Who may be the fortunate *savant* whom the world has to thank for demonstrating that yellow fever emanates from rays, the curious in science will be anxious to know. The description of rays, with illustrations, &c., &c., will, doubtless, shortly follow, and thus prevent inquirers being kept in unnecessary suspense. Communications in the same number favour the impression that the water contamination *mania*, bearing on the propagation of cholera, is beginning to admit of something like a return to a low form of common sense.

The water drinkers cannot admit that even in the cholera districts they died in the average proportion, and I congratulate them that they practically ignore by their protests the unscientific and feebly supported assertions on the question.

The much lamented Dr. Snow may be regarded as the proponent of the water contamination theory, founded mainly on the outbreak of cholera near Golden-square, London, which was supposed to have originated, and very generally believed (consequent on the constant repetition, both in medical and non-medical circles), from contamination of the Broad-street pump water by the secretions of cholera patients, and apparently confirmed by the oft-repeated assertion that the arrest of the disease was due to the locking up of the said pump. The locking up of the pump had about the same amount of influence in arresting the disease that the drinking of the water had in its sudden irruption, as the water was not even suspected until the disease had begun to subside, which upon that theory it should not have done, the water having necessarily become daily more contaminated and poisonous.

The same number of the journal to which I allude has also the temerity to re-proclaim another error:—

"Not the least curious fact in the epidemic part of the history of the year has been the repeated importation of yellow fever, extending in Swansea, in August last, to the general community, and causing fifteen deaths out of twenty cases."

There was no yellow fever, extending in Swansea, in August last, to the general community, nor in any month of the past year, or of any other year. There was yellow fever in Swansea in September and October, 1865, but the deaths were not fifteen in twenty cases. Dr. Buchanan, appointed by the then Government to report on the outbreak of yellow fever at Swansea, remarks—"That there were twelve centres from whence the disease, if it had been communicable from person to person, had the opportunity of spreading, and that many of these localities were perfectly adapted for the spread of contagious diseases, yet in no single instance out of all these did a single person get yellow fever, or any disease simulating it."

Thus is it demonstrated beyond a doubt that the disease did not spread to the general community.

With such examples before us, what dependence can be placed on the present teaching of a periodical which in years past could scarcely be accused of such superficiality and scientific inaccuracy, whatever other charges might have been fairly launched against it?—I am, sir,  
EDWIN HEARNE.

### CLITORIDECTOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I had the *best* reasons for believing that a Committee of independent Fellows of the Obstetrical Society, in whom I have confidence, would have been proposed at the last meeting of the Society, and was sorry to find that the Council would not entertain the subject. I have now, therefore, written to the new Council to say, that if they will appoint a fair and impartial committee, I will place every facility in their hands for investigating my cases most rigidly. In the meantime, I feel confident that the new President will not allow personalities and unjustifiable language to be used against any Fellow in future discussions; and I beg to remind all Fellows of the Society that I am in no way to be held accountable for any damage the Society may sustain by the discussion of Dr. Tanner's paper.—I am, sir, your obedient servant,

I. BAKER BROWN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Not being an operator, it is not my intention to enter into the merits or demerits of this operation, the discussion being in much more able hands, but writing under the above heading, I feel in justice to my friend Mr. Baker Brown, I ought to state that he has performed that operation both in the Home and in private with my entire concurrence, and with marked benefit to my patients, who, I am satisfied, under medical treatment alone, would have remained in their distressing condition until now.

Dr. Greenhalgh in his letter published in the *Lancet* of the 29th ult., referring to his visits to the London Surgical Home, after paying a well-merited compliment to Mr. Baker Brown as an operator, goes on to say:—

"But I saw more than that, truth compels me to add that I saw these scenes and heard details which I will not further characterise than by saying, that I thenceforth advised my class never again to visit that Institution, and came to like resolution as regards myself."

This statement embodies a charge by insinuation of the *gravest* nature against some one or more belonging to or present at the Home; and as one of the late Medical Visitors, and a constant attendant at the operations for years, I feel I should be neglecting my duty, did I not notice this part of Dr. Greenhalgh's letter, my experience being the very reverse of his.

I have found the Home in every sense what its name implies, and it is not, and should not, be spoken of as an ordinary hospital. There gentlewomen, that would not go to a regular hospital, receive skilled medical and surgical attendance with careful nursing that would otherwise be beyond their reach, and not only has the Institution been recognised by royal favour after the test of personal inspection. But I have in my possession a mass of written evidence of its work, from medical men and grateful patients, who having been there, give as the result of their experience a very different verdict to that of Dr. Greenhalgh, and there is at this moment a lady patient of mine there who will fully confirm every word I have written in its praise.

In conclusion, I would ask Dr. Greenhalgh in fairness, to myself and the other gentlemen he has met there, to state fully what he either saw or heard, and when to justify him in debarring his class from the particular field of instruction, he and the profession from all parts of the world have been pleased so long to enjoy.—I am, sir, your obedient servant,

HOLT DUNN.

### THE CLERKENWELL CASUAL WARDS.

THE following further correspondence has taken place on this subject in the *Times*:—

"SIR—I must beg your permission to point out grave misstatements made by a Clerkenwell guardian, Mr. John W. Hopkins, in his letter in the *Times* of this morning. I did not cross-examine, in any manner whatever, the porter relative to the charge of drunkenness which he made against the casuals, and his statement was that 'he suspected they were drunk because they were lounging against the wall,' and his testimony

that they staggered when going into the ward was entirely uncorroborated. The police-constable said he thought they had been drinking, but as he did not see them move, never spoke to them and only glanced at them once by means of his lantern, and as he was to some extent interested in establishing this view of the case, he having been reported to his superiors for certain neglect of duty in connection with the affair, his testimony does not go for much in this particular. But, let it be observed, he does not say the men were drunk, for he stated 'they were perfectly capable of taking care of themselves.' Both the porter and he allowed that not one word was said about the men being drunk, and I was the only person charged with being intoxicated, and that by the porter; for the policeman himself, the policeman on the next beat, and a tradesman who was brought to his door by an alarming fight in the neighbourhood—all attested to my perfect freedom from the slightest influence of drink. The tradesman also expressed his conviction that the two men were sober, and had the charge of drunkenness been made against them I should have called attention to their condition. My evidence on this point, however, can be further supported, if the Poor-law Board should desire to be further convinced.

"I did cross-examine the porter about a statement made to the guardians by his superior, the superintendent, and considered by them as a perfectly 'satisfactory explanation' of the charge. This was, that the policeman had pronounced the casuals and their friend to be 'all three drunk.' The porter denied authorizing his superior to say so.

"The loud knocking at the door of the ward was only loud after repeated softer knocks, which was continued at intervals of a few minutes, and I was justified in knocking louder when no one answered the lower knocks. I measured from the place spoken of by the policeman as where he heard the knocking, and instead of its being 130 yards distant, I found it less than 80 fair paces—about half the distance stated by Mr. Hopkins. The guardians had left no other means of communicating with the inside than by knocking or hitting the door with the fist.

"With regard to the steps I took to cause inquiry into this matter, I explained to the guardians that I took the readiest means that were at hand. The manner in which the majority of the guardians conducted themselves when I went uninvited on Thursday night (having previously communicated with the clerk), confirms me in my opinion that I took the best means. Of course I could not expect much courtesy from a body that, when called to order by the chairman on account of the Poor-law Commissioner being present, had a member to exclaim, 'I don't care for the Poor-law Commissioners, or anybody else.'

"Allow me to say, in regard to Mr. Hopkins's last statement, that I was officially informed the guardians would not permit any unofficial person to visit the wards.

"I can add another incident in illustration of 'man's inhumanity to man,' at the Clerkenwell casual wards. This evening on passing the wards at a little after five o'clock, I saw a poor ill-clad fellow waiting outside in the perishing cold of the streets. He told me he had made application for admission and had been told to come in another hour. I went and fetched a guardian, Mr. Poley, a gentleman whom I know to be a humane man. He knocked and asked the superintendent why the casual was not admitted. The superintendent owned to telling the man to come in another hour, and knew the Act of Parliament by heart, and quoted it to the effect that the casuals were to be relieved from six P.M. in these winter months; but he owned, on further interrogation, that there was nothing in the Act which rendered it imperative to keep the ill-clad wretches who seek this relief in the bitter cold. It turned out that the guardians, in their 'hearty desire and anxious wish,' to quote Mr. Hopkins, to carry out the law, have provided no place for the men casuals to sit in, and they have been obliged to take their food in the open yard. A place was found, at the instance of Mr. Poley, for the too early casuals to rest in, and a precedent established for taking others in.—I am, sir, your obedient servant,  
JOHN WHILE."

"Sir,—I hoped not to have troubled you with another letter, but the appearance of one in the *Times* of to-day from Mr. While has left me no alternative, I am still of the same opinion respecting the cases of the two applicants for admission—viz., that they were drunk, and consequently should not have been admitted into the casual wards, and I submit that my opinion is as likely to be correct and unbiased as Mr. While's, who was the plaintiff in the case, as we well know that persons in that position usually take views favourable to themselves.

"I do not consider that Mr. While has answered my letters in any particular, except that the distance I find from the casual ward outer door to Peartree-court to be on measurement 98 yards, and as I said about 130 yards, I made an error of 32 yards, but the fact of being heard by the policeman 98 yards proves that he had little regard for the slumbers of the many poor wayfarers sleeping in the wards at the time. He has given no reply as to my statement that the Clerkenwell guardians can have no interest in "keeping down the number of admissions" as that body is recouped by the Metropolitan Board, under the Houseless Poor Act, and his answer to my question, "Why he did not first make the Board of Guardians acquainted with the facts before he wrote to the *Times*" is weak and puerile. Mr. While admits all this tacitly by his proceeding, before he answered me, in search of fresh cruelties at the wards, in order to strengthen his reply to my letters. I repeat it, as one of the guardians, though Mr. While sneers and quotes my words, that it is our "hearty desire and earnest wish" that there shall be no infraction of the law in the management of our casual wards.

"In reply to the new case brought before your readers in Mr. While's letter of to-day, I beg to say that the poor fellow who is described as shivering in the forecourt of the Clerkenwell casual wards was a hale, hearty man, well-clothed, and had come from a vast distance—Hoxton! As to the reason he gave that he was not admitted, I submit that the legal hour had not arrived for his admission, as the Act of 28th Victoria, cap. 32, gives the hours of between six in the evening and eight in the morning in the months between October and March inclusive. In addition to this, allow me to inform you, sir, that Clerkenwell deals more mercifully with applicants for admission than other parishes. Islington, St. Luke's, Shoreditch, &c., compel all applicants to the casual wards to go to the police stations for orders, and I have seen thirty or forty poor wretches shivering outside the police stations awaiting orders, and to none are those orders given before six o'clock, and the police are thus employed by the sanction—yes, and the recommendation, of the Poor-law Board. Any of your readers can convince himself of the truth of my statement by visiting the police stations at that time.

"I deny that the casuals have to eat their food in the open yard; the place used for that purpose is an enclosed shed, not so warm and comfortable as it should be, but Mr. While knows that all the guardians have been compelled to make the best arrangements they could until they got a lease of the premises; besides which, when one of the Poor-law inspectors visited the place he made no objection to it, previous to his certifying as to the fitness of the establishment for its purpose.

"Mr. While says nothing about the comfortable warm bath each has, nothing of the pint of hot gruel and  $\frac{1}{2}$  lb. of bread, night and morning, each receives, nothing of the clean warm night shirt and comfortable bed on lath iron bedsteads and warm rugs to cover them, nothing of the genial gaslight—these things are never mentioned by writers of Mr. While's class, who have an eagle eye at finding out small defects, but are blind to such redeeming qualities as I have mentioned.

"I claim, sir, to have as warm a sympathy for the poor as he, and I shall be grateful to him, or any one, who will communicate any real ground of complaint against the officials of not only our casuals ward, but also of any other ramification of parochial Poor-Law Government in this parish. I shall not further reply.—Yours obediently,

JOHN W. HOPKINS, Guardian.

## UNIVERSITY OF DUBLIN, TRINITY COLLEGE.

### EXAMINATION FOR SURGICAL DEGREES.

MICHAELMAS, 1866.

#### DESCRIPTIVE AND SURGICAL ANATOMY.—PROFESSOR M'DOWEL

1. The relations of the lachrymal sac?
2. Describe the temporal muscle, and mention its relations.
3. Give a description of the temporal arteries and nerves, and mention the several sources from which they arise.
4. The meaning of the term amphiarthrosis? Give the most remarkable examples of it in man.
5. In what situations on the cranium is the application of the trephine inadmissible?
6. Describe the linea alba, and mention the operations which it may be requisite to perform in this region.

7. Describe the progressive stages of ossification of the humerus.
8. Describe, anatomically, the successive steps of the operation of ovariectomy.
9. The relations of the femoral artery in Scarpa's triangle?
10. Describe the method of removal of the eyeball by enucleation.

DR. ADAMS.

1. The symptoms of a stricture of the œsophagus?
2. With what affection might organic stricture of the œsophagus be confounded?
3. State the post-mortem appearances of stricture of the œsophagus; and what other organs besides the œsophagus are usually found implicated.
4. Give the symptoms of organic stricture of the rectum.
5. Contrast these symptoms of stricture of the lower part of the rectum with those of a narrowing of the colon where it approaches the rectum.
6. Under what circumstances would you be unwilling to recommend the excision of a scirrhous tumour of the female breast?
7. What varieties of appearances have you noticed in the cutaneous covering of a scirrhous breast?
8. In performing the operation of laryngotomy in the case of an adult, what should be the size of a tube to be inserted in the opening made in the larynx?
9. What are the attentions to be paid after the operation of laryngotomy to the condition of the tube introduced?
10. When a morsel of food becomes suddenly arrested at the lowest part of the pharynx or commencement of the œsophagus, explain the cause of the sudden and sometimes fatal dyspnoea which supervenes. Is the cause of the dyspnoea mechanical or vital?

DR. R. W. SMITH.

1. Give a description of Pott's gangrene.
2. Mention the principal forms of mammary abscess.
3. Describe that form which has its seat in the gland itself.
4. What are the peculiarities of atrophic cancer of the breast?
5. Mention the various conditions which, if present, would prevent your removal of a cancerous breast.
6. What operations have been proposed in cases of cancer of the tongue?
7. Describe the characters of luxation of the head of the femur upon the pubis.
8. What would be your treatment in a case of mercurial erethismus?
9. What operations are performed in cases of entropion?
10. Signs of what Mr. Hey has termed "internal derangement of the knee-joint."

## EXAMINATION FOR MEDICAL DEGREES.

DR. R. W. SMITH.

1. Local and constitutional signs of hernia humoralis?
2. Mention the various modes of treatment.
3. Symptoms of strangulated hernia?
4. Signs of gangrene of the intestine?
5. Mention the modes of treatment you would have recourse to in a case of recent strangulation before proceeding to operate.
6. If, upon laying open the sac, you found the intestine mortified, what would be your line of treatment?
7. What dangers attend abscesses in the parities of the abdomen?
8. What methods have been recommended for the local treatment of anthrax?
9. Write a prescription for a fermenting poultice.
10. What are the signs of a fracture of the patella? How would you treat this injury?

INSTITUTES OF MEDICINE.—PROFESSOR LAW.

1. What is Prout's classification of alimentary substances?
2. How does an adherent pericardium affect the nutrition of the heart?
3. How does position affect the number of the pulse?
4. How many different renal affections are comprised under the general designation of Morbus Brightii?
5. What is the pathological lesion in *ataxie locomotrice*?
6. What are the arguments that may be adduced to prove that typhus and typhoid fever are essentially different diseases

7. What are the lesions usually found after death in typhoid fever?
8. Who first described yellow softening of the brain?
9. What explanation did he give of it?
10. What surgical operation proved the correctness of his explanation?

MIDWIFERY, &amp;c.—DR. SINCLAIR.

1. Fœtal head in the occipito-cotyloid position at the brim; describe the mechanism of the child's passage through the pelvis.
2. Demonstrate the utility of auscultation in determining the position of the fetus in utero, at full term.
3. Mention the puerperal causes of death; of the mother and of the child.
4. Edema gravidarum of the primiparous; its prognostic import, and the treatment for its removal?
5. Mention the least, and the most fatal form of complex labour as regards the mother.
6. Give a short history and describe the operation of symphysectomy; also state your opinion with respect to its utility.
7. What is meant by metria?
8. Pruritus vulvæ, symptoms, causes, and treatment?
9. Nature, origin, and treatment of cephalæmatomata?
10. Write the following prescriptions for a child two days old:—

- I. A carminative with opium.
- II. A purgative.

MEDICAL JURISPRUDENCE.—ROBERT TRAVERS, A.M., M.B.

1. How are hypostatic stains developed on the body, after death, to be distinguished from the results of confusion during life?
2. Enumerate the conditions that might be mistaken for cadaveric rigidity, and the diagnostic characters of each.
3. State the circumstances by which the progress of decomposition in the dead body may be affected, retarded, or accelerated.
4. A dead body having been found immersed in water, from what can you determine whether the death has been by drowning, or by some other cause?
5. Distinguish the coma of inebriation from that of apoplexy, and of concussion of the brain.
6. To what objections is *Reinsch's* process for the detection of an arsenical poison liable? and how are they to be obviated?
7. What forms of poisoning might be confounded with, or mistaken for, malignant (or Asiatic) cholera; and on what would the diagnosis be established?
8. By what characters observed in the anatomical autopsy, will death from exposure to H<sub>2</sub>S, either alone, or with some other noxious gas, and but little diluted with atmospheric air, be recognisable?
9. To what is due the difficulty of determining whether wounds were inflicted during life, or after death?
10. What circumstances would you admit as criteria to distinguish *simulated* from real insanity.

BOTANY.—REV. DR. HAUGHTON.

1. Illustrate the following forms of stem: *articulate, nodose, triquetrous, quadrilateral, ribbed*.
2. Describe the law of Phyllotaxis in alternate-leaved plants.
3. Describe the *Digitalis purpurea*, referring it to its natural family, and stating its habitat.
4. Describe the officinal method of using the *Digitalis purpurea*, its adulterations, and physiological effects.
5. Describe the natural family *Alismaceæ*, illustrating your description by an account of the *Alisma plantago*.
6. Describe the *Linum catharticum*, giving the characters of its natural family.
7. You are required to distinguish between the *Caprifoliaceæ* and the *Rubiaceæ*; and to divide the latter into the *Stellata*, the *Coffea*, and the *Cinchona*.
8. Give an account of Forbes' theory of "specific centres," and illustrate it by examples drawn from the Vegetable Kingdom.
9. Draw figures of an *auriculate*, a *perfoliate*, a *connate*, and of a *pinnatifid* leaf.
10. Draw a diagram showing the horizontal cross section of the leaf-bud, imbricated and quincunical, of a Poplar whose Phyllotaxis is two-fifths.

## Medical News.

**APOTHECARIES' HALL, LONDON.**—The following are the names of the gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, the 3rd of January:—Edward Nettle-ship (King's College), Kettering, Northamptonshire. On Thursday, the 10th of January:—William Edward Williams (St. Bartholomew's Hospital), Llanhilleth, Monmouthshire; Thomas Edward Stainthorpe (Middlesex Hospital), Hexham Abbey; Henry Summerhayes (St. Thomas's), Ealing, Middlesex. The following gentlemen also on the same day passed their first examination:—Walter Hart, King's College Hospital; John Chisholm McDonald, Westminster Hospital.

**THE HOSPITAL FOR STONE.**—The *British Medical Journal* has been given to understand that Mr. Walter Coulson, having regard to the view which his colleagues have taken of his conduct in resuming office as Surgeon at St. Peter's Hospital, after receiving their support as candidate for the assistant-surgency of St. Mary's Hospital under the impression that he had finally ceased to be connected with St. Peter's, has resolved to resign his appointment at St. Mary's, reserving to himself the right of presenting himself anew as candidate for the vacancy occasioned at St. Mary's by his resignation.

**GLASGOW LYING-IN HOSPITAL.**—At a meeting of the Directors of this hospital, held on the 3rd January, the following medical officers were appointed:—*Consulting Physician*, Dr. Andrew Anderson; *Consulting Surgeon*, Dr. George Buchanan; *Physician-Accoucheurs*, Dr. J. G. Wilson, and Dr. R. D. Tannahill; *Assistant Physicians and Dispensary Physicians*, Dr. Donald Dewar and Dr. George Yeamon.

**MÖLLER'S PURE COD-LIVER OIL.**—This oil, which is free from any disagreeable smell or taste, obtained the great Medal of the International Exhibition in London in the year 1862, and has been honoured with other similar testimonials bestowed in foreign countries. It is stated that the King of Sweden and Norway has presented the "Vasa" order to Mr. Möller, in recognition of the peculiar system by which the oil is prepared, and the physician to that Monarch has expressed, in a letter to Mr. Möller, his favourable opinion of its medicinal qualities and its easy digestibility. It is now introduced into Great Britain, and is sold by all chemists.

**MEDICAL CHARITIES.**—The funds of the Royal Infirmarys of Dundee and Perth have been increased by the munificent bequests of £1000 each from the Rev. John Spence, minister of Kinnaird, who has also left £12,000 for the purposes of founding as many bursaries in sums of not less than £50 each per annum to industrious students of the Universities of St. Andrews and of Edinburgh.

**HARVEIAN SOCIETY.**—At the annual meeting of this Society, on January 3rd, the following gentlemen were elected officers for the ensuing year:—*President*—\*J. E. Pollock, M.D. *Vice-Presidents*—T. Ballard, M.D.; \*W. F. Cleveland, M.D.; \*Ernest Hart, Esq.; J. B. Walker, Esq. *Treasurer*—Henry William Fuller, M.D. *Hon. Secretaries*—J. Brendon Curgenvin, Esq.; Charles R. Drysdale, M.D. *Council*—Victor De Meric, Esq.; J. Eardley, Esq.; John Evans, Esq.; J. Gayleard, Esq.; \*R. S. Jeffs, Esq.; J. Stewart Lamb, M.D.; James R. Lane, Esq.; J. Z. Laurence, Esq.; \*H. W. Lobb, Esq.; Edwin Lowe, Esq.; \*Duncan Menzies, M.R.C.P.; \*J. Rushforth, Esq. The retiring President, Dr. Tyler Smith, read a very able address, embodying the report and suggestions of the Committee on Infanticide. So important was the report considered that it was unanimously resolved it should be printed.

\* An asterisk is prefixed to the names of those gentlemen who did not hold the same office the preceding year.

**ROAD REFORM IN SCOTLAND.**—A deputation of the Chamber of Agriculture waited upon the Lord-Advocate of Scotland on Wednesday, to present the resolution lately adopted by that body on the subject of road reform. Mr. Maclagan, M.P., Mr. Pagaw, of Cupar-Fife, who was the originator of the road reform movement in Scotland about 20 years ago, and Mr. McLaren, M.P., addressed his Lordship in support of the petition of the Chamber for the introduction of a general measure, similar in principle to that adopted by several of the counties, and following out the recommendations of the Road Commissioners. The Lord-Advocate expressed his satisfaction in re-

ceiving the deputation, stated that he would bring the views of the deputation before Government, and that the deputation might be assured that any legislation on the subject which he would recommend would be in conformity with the principles recommended in the Commissioners' report.

**WORKHOUSE SURGEONS.**—It would appear that young medical men willing to accept workhouse appointments are very scarce, or that parochial authorities are very fastidious in their selection. Mr. Butt, the resident medical officer of St. Pancras Workhouse, having resigned his office, the vestry, with whom the appointment rests, directed advertisements to be issued for candidates to fill the vacant office, at a salary of £160, rising to £200 a year, with vaccination fees, and board and lodging. A special meeting of the vestry was held to receive applications from candidates, examine testimonials, &c., and to make a selection of two or three, from whom the vestry at its ordinary meeting was to elect one. Only one, however, of the candidates was considered up to the parochial standard, and fit to be sent to the vestry for election. It was then said, "We cannot send up only one to the vestry for election, for that would give them no choice; and as to that one, he is thirty-five years of age, and if he was a clever man wouldn't he have got on better by this time, and been above taking a workhouse appointment? So we had better reject them all and advertise again, and next time we may have better luck." It was accordingly resolved to reject all the candidates, and advertise again.—*Pall-Mall Gazette*.

**SANITARY ACT OF 1866.**—The regulations under this Act relating to lodging-houses are now coming into operation. Rules approved by the Home Secretary have been issued by several of the districts in the metropolis. Those issued by the Board of Works for the St. Giles's district are very stringent. Among the most important it is specified that no person shall let any house, or part of a house, in lodgings, or to be occupied in lodgings by members of more than one family, and in which more than two persons shall sleep in one room, until such house, and the person proposing to let the same, are registered in the office of the Board of Works. In no case will an accommodation of less than 400 cubic feet of space be allowed to each person. Persons letting such house, or part of a house, must have the walls and ceilings of every room, &c., thoroughly cleansed and limewashed at least four times every year. Cellars are to be cleaned out once a week, and limewashed as often as needed. The rooms are to be ventilated, &c., to the satisfaction of the medical health officer. Proper accommodation must also be provided for washing, and such a supply of water for the use of lodgers, with proper covered cisterns, as shall be satisfactory to the health officer. The cistern to afford at least fifteen gallons a day to each inmate. The dustbin must be emptied once a week, and for every twenty persons a separate water-closet is to be provided. Every house is to be properly drained. Every owner not resident in or near the registered house, must appoint, as agent, some person who is resident in or near to the house, to see that the regulations are carried out. Every house and room shall be open to the medical health officer for inspection between the hours of eight o'clock A.M. and ten o'clock P.M. Any persons violating the regulations will be liable to a penalty not exceeding 40s. for any one offence, with an additional penalty not exceeding 20s. for every day during which a default in obeying such regulations shall continue. The regulations issued by the Poplar district, also approved by the Home Secretary, are of a somewhat similar description; but there are additional clauses to the effect that no room the ceiling of which is on a level with or below the level of the footpath or roadway immediately adjoining, and no room used as a kitchen or scullery, and no room not lighted and ventilated directly from the exterior, and no room on the roof of the house not furnished with an open fireplace or flue, shall be permitted to be occupied as a sleeping-room, nor shall any underground room be permitted to be so occupied unless specially certified by the medical health officer as fit to be so occupied. The number of persons in each sleeping-room is to be determined by the cubical contents of the room; for instance, if the room is used only as a bedroom, there is not to be more than one person to every 300 cubic feet of air; if used as a sleeping room and also as a day room, then there is not to be more than one person to every 400 cubic feet of air. Persons of different sexes are not to occupy the same sleeping room, except one married couple, or parents with children under ten years of age. When a person is attacked with fever, small-pox, or other infectious disease, immediate notice must be given to the medical health officer.

**THE HORRORS OF VIVISECTION IN FRANCE.**—In a building or shed open to the air on one side lay six or seven living horses, fixed by every possible mechanical contrivance by the head and feet to pillars to prevent their struggling, and upon each horse were six or seven pupils employed in performing different surgical operations. The sight was truly horrible. The operations had begun early in the forenoon; it was nearly three o'clock when we entered the place, so that the poor wretches, as may be supposed, had ceased being able to make any violent struggles. But the deep heaving of the still panting chest, and the horrible look of the eyes, when such were remaining in the head, while the head was lashed to a pillar, were harrowing beyond endurance. The students had begun their day's work in the last vital parts of the animal; the trunks were there, but they had lost their tails, ears, and hoofs, and the operators were now engaged performing the more important operations, as tying up arteries, trephining the cranium, cutting down the more sensitive parts, on purpose, we were told that they might see the retraction of certain muscles by pinching and irritating the various nerves. One animal had one side of his head completely dissected, and the students were engaged in laying open and cauterizing the hock of same side when we entered.—*Veterinarian.*

## Notices to Correspondents.

To our Subscribers.—In reply to numerous inquiries, we beg to say, that the INDEX for the last Volume is in course of preparation, and will be issued to our subscribers as soon as it has been completed.

In consequence of the illness of the Editor of our Irish Hospital Reports we are reluctantly obliged to issue this number without any material under this head. We hope to have them resumed in our next number.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

Every MS. should bear the Name and Address of the Sender.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

*A Medical Student.*—The pay of the Surgeons of the Peninsular and Oriental Steam Navigation Company on the Mediterranean or home lines commences at about £120 per year; that of those on the Indian lines at about £160 per do. The pay of the medical officers is progressively increased after certain periods of service. The surgeon receives remuneration for each life he examines for the Insurance or Superannuation Fund, chiefly established for the benefit of the officers, crews, and other employees, of the P. and O. Royal Mail, and some kindred services.

Mr. Richardson's letter has been received and will appear in our next Number.

## Medical Diary of the Week.

### ROYAL INSTITUTION.

**TUESDAY.**—Jan. 15th, at three o'clock, Rev. Charles Kingsley "On the Ancien Régime as it existed on the Continent before the French Revolution."

**THURSDAY.**—Jan. 17th, at three o'clock, Rev. Charles Kingsley, "On the Ancien Régime as it existed on the Continent before the French Revolution."

**FRIDAY.**—Jan. 18th, at eight o'clock, Professor Tyndall, "On Sounding and Sensitive Flames."

**SATURDAY.**—Jan. 19th, at three o'clock, Rev. Charles Kingsley, "On the Ancien Régime as it existed on the Continent before the French Revolution."

## Vacancies.

**BIRMINGHAM GENERAL DISPENSARY.**—Honorary Surgeon.  
**NORTHAMPTON GENERAL INFIRMARY.**—Assistant to the House-Surgeon.

### POOR-LAW MEDICAL SERVICE.

The area of each district is stated in acres. The population is computed according to the last census.

*Chailey Union.*—Third District; area 3103; population 1162; salary £16 per annum.

*Cricklade and Woolton Bassett Union.*—First District; area 10,760; population 2985; salary £40 per annum.

*Tavistock Union.*—Beerferris District; area 5850; population 2847; salary £22 6s; 8d. per annum.

## Appointments.

**ALLISON, J., L.K.Q.C.P.I., M.R.C.S.,** has been appointed Honorary Visiting Medical Officer to the Barrow-in-Furness Hospital and Dispensary.

**ARMISTEAD, W., M.B., C.M.,** has been appointed House-Surgeon to the Barrow-in-Furness Hospital and Dispensary.

**BEARDSLEY, A., M.R.C.S., L.S.A.,** has been appointed Honorary Consulting Surgeon to the Barrow-in-Furness Hospital and Dispensary.

**ELLIS, T. S., M.R.C.S.E.,** has been appointed Surgeon to the Lying-in Charity, Gloucester.

**EVANS, Mr. E. C.,** has been appointed House-Surgeon and Secretary to the Glamorganshire and Monmouthshire Infirmary and Dispensary, Cardiff.

**HARRIS, Dr. GWYNNE,** has been appointed Surgeon to the Royal Artillery, Popton Battery, Milford Haven.

**SINCLAIR, W., M.D., L.R.C.P. and S.E.,** has been appointed Honorary Visiting Medical Officer to the Barrow-in-Furness Hospital and Dispensary.

**SUTTON, Dr. H. G.,** has been appointed Fourth Assistant-Physician to the London Hospital.

**STARKE, P. W., M.D., L.R.C.P. and S.E.,** has been appointed Honorary Visiting Medical Officer to the Barrow-in-Furness Hospital and Dispensary.

**TERND, Dr. THEOPHILUS W., L.K.Q.C.P.I., M.R.C.S. Eng., &c.,** has been appointed Admiralty Surgeon and Agent at Southampton, vice J. King Sampson, F.R.C.S. Eng., resigned.

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

**ARMSTRONG.**—On December 13, at Fulford, near York, the wife of L. Armstrong, M.D., 13th Hussars, of a son.

**BLOMFIELD.**—On December 23, at 8, Rye-lane, Peckham, the wife of Dr. Blomfield, F.R.C.S., of a son.

**CHAPMAN.**—On January 2, at Old Friars, Richmond-green, Surrey, the wife of F. Chapman, M.R.C.S.E., of a daughter.

**HOUGHTON.**—On December 30, at 6, Mount-street, Grosvenor-square, the wife of H. G. Houghton, M.D., of a daughter.

**SPICKERNELL.**—On January 4, at Eastern-parade, Southsea, the wife of Dr. G. E. Spickernell, of a daughter.

**WATSON.**—On December 29, at Little Huthwaite, Wortley, near Sheffield, the wife of A. M. Watson, M.D., prematurely, of a son still-born.

### MARRIAGES.

**HUXTABLE—WALKER.**—On January 1, at the Parish Church, East Budleigh, Devon, W. Huxtable, M.R.C.S., Belmont-villa, Budleigh Salterton, to Eliza, widow of the late Samuel Walker, Esq., Grove House, Sidmouth. No cards.

**JOHNSON—FRECHEVILLE.**—On January 4, at South Tedworth, Hants, W. Johnson, Esq., M.D., to Mary, eldest daughter of R. R. Frecheville, Esq. No cards.

**JACOB—GREENE.**—On January 10, at Athy, Augustus Hamilton, youngest son of Arthur Jacob, Esq., M.D., of Dublin, to Annie, youngest daughter of John Greene, Esq., Millbrooke, Mageny.

### DEATHS.

**ATKINSON.**—On January 6, B. Atkinson, M.R.C.S.E., J.P. for the county of Bucks, at the Rookery, Great Marlow, aged 64.

**CABILL.**—On December 21, A. Chail, M.D., Surgeon 25th Regiment, at the Avenue, Berwick-on-Tweed, aged 84.

**DESMOND.**—On December 23, J. Desmond, M.D., Edin., at Nelson-place, Youghall, Cork, aged 79.

**KITSON.**—On December 24, J. B. Kitson, L.R.C.P. Edin., of Newport, Co. Tipperary, aged 26.

**MARTIN.**—On January 7, G. A. Martin, M.D. Edin., M.R.C.P. Lond., at Belgrave House, Ventnor, Isle of Wight, aged 60.

**PICKTHORN.**—On October 21, Dr. G. R. Pickthorn, R.N., Assistant-Surgeon H.M.S. *Challenger*, at Auckland, New Zealand, in his 23th year.

**ROSS.**—On December 31, J. Tucker Ross, R.N., late Assistant-Surgeon Royal Naval Hospital, Simon's Bay, Cape of Good Hope.

**VISE.**—On January 6, C. Vise, M.C.C.S.E., at Spalding, Lincolnshire, in his 66th year.

# The Medical Press & Circular.

STAMPED CIRCULATION FOR THE YEAR ENDING JUNE 30, 1866.

THE following extract from the Parliamentary Return recently published, represents the relative Issue of impressed Stamps of the principal weekly journals in Ireland, exclusive of the *General Advertiser*. The period included in the return comprises the half-yearly terms immediately preceding and succeeding the incorporation of THE MEDICAL CIRCULAR AND MEDICAL PRESS:—

Stamps Issued.	Annual Total.	Weekly Average.
Farmers' Gazette ... ..	115,150	2214
Medical Press and Circular ... ..	62,400	1200
Warder ... ..	42,500	817
Catholic Telegraph and Irish Sun ... ..	16,225	312
Nation ... ..	35,750	683
Weekly Freeman's Journal ... ..	30,000	577
Irishman ... ..	22,500	433
Agricultural Review ... ..	5,939	114
Weekly News ... ..	8,277	160
Irish People ... ..	2,500	45
Commercial Journal ... ..	1,470	29
Despatch ... ..	1,500	29
Mercantile Advertiser ... ..	—	—
Advertising Gazette ... ..	—	—

It will be perceived from this official testimony that THE MEDICAL PRESS AND CIRCULAR possesses the second largest Weekly Stamped Issue in Ireland. It is to be remembered that these returns only represent the Postal Issue, and entirely omits that part of the impression distributed by hand or through agents.

## ROYAL COLLEGE of PHYSICIANS of LONDON.

FIRST PART OF THE PROFESSIONAL EXAMINATION FOR THE LICENCE.—The next Examination of Students who have completed Two Years of Professional Study at a recognised Medical School will commence on Tuesday, February 5th.

SECOND PART OF THE PROFESSIONAL EXAMINATION.—An Examination of gentlemen who are eligible for admission to the Second Examination for the Licence will commence on Tuesday, February 12th.

Registered Medical Practitioners qualified before January, 1861, are admitted to Examination under Special Bye-law.

Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all certificates and testimonials required by the Bye-laws are to be left at the same time.

Fall-mall East, 1867.

H. A. PITMAN, M.D., Registrar.

## HOSPITAL FOR DISEASES OF THE THROAT, 32, GOLDEN-SQUARE, W.

CONSULTING PHYSICIANS: Archibald Billing, M.D., F.R.S.; William Jenner, M.D., F.R.S.

CONSULTING SURGEON: Sir William Ferguson, Bart., F.R.S.

PHYSICIANS: Patrick Fraser, M.D.; Morell Mackenzie, M.D.

SURGEON: George Evans, Esq.

Free Laryngoscopic Demonstrations are given every Thursday, at Two o'clock, by Dr. Morell Mackenzie.

Fee for three months' Medical Practice, £3 3s.; perpetual, £5 5s.

Clinical Assistants are appointed from the Perpetual Students.

GEO. G. WITHERBY, Hon. Sec.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

NOTICE is hereby Given that the next QUARTERLY EXAMINATION will be held at the College, on TUESDAY, the 12th and TUESDAY the 19th FEBRUARY, at three o'clock P.M.

Candidates for Examination shall return their names to the Registrar of the College, and lodge their Fees and Certificates, on or before the 29th day of January.—By Order,

January 9th, 1867.

JOHN BRENNEN, Registrar.

## NAAS UNION.

### KILDARE DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The COMMITTEE of MANAGEMENT of the above Dispensary District will, at their Meeting to be held at the Dispensary, at Kildare, on TUESDAY, the 22nd JANUARY, 1867, at the hour of Twelve o'clock noon, proceed to appoint a Medical Officer duly qualified, in accordance with the Order of the Poor-law Commissioners, at a salary of £80 per annum, exclusive of Fees for Registration and Vaccination.

The Gentleman appointed will be required to reside in the town of Kildare, and commence his duties on the 1st February, 1867.

Applications from Candidates, who are required to be in attendance, accompanied by testimonials, &c., will be received by me up to Twelve o'clock on the above day.

CHARLES BERGIN, Hon. Secretary.

Kildare, 2nd January, 1867.

## GALWAY UNION.

The COMMITTEE of MANAGEMENT of the SPIDDAL DISPENSARY DISTRICT, Comprising the Electoral Divisions of Furbough, Spiddal, Killannin, Kileummin, and Selerna, will, on WEDNESDAY, the 16th JANUARY next, at the Spiddal Dispensary, elect a duly qualified person, who shall reside within the District, to discharge the duties of

MEDICAL OFFICER, at a Salary of £70 a-year, together with Registration and Vaccination Fees.

Applications, with testimonials of qualifications, &c., to be addressed to A. W. BLAKE, Esq., Chairman of the Committee, Furbough, Barna.

The personal attendance of Candidates on the day of election is required.

29th December, 1866.

## GALWAY UNION.

The COMMITTEE of MANAGEMENT of the MOYCULLEN DISPENSARY DISTRICT, Comprising the Electoral Divisions of Moycullen, Slievancena, and Tullokyne, will, on WEDNESDAY, the 16th JANUARY next, at the Moycullen Dispensary, elect a duly qualified person, who shall reside within the District, to discharge the duties of

MEDICAL OFFICER, at a Salary of £70 a-year, together with Registration and Vaccination Fees.

Applications, with testimonials of qualification, &c., will be received by NOEL T. SMITH, Esq., Hon. Sec., Drimecong, Moycullen.

The personal attendance of Candidates on the day of Election is required.

29th December, 1866.

## NAAS UNION.

### NEWBRIDGE DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The COMMITTEE of MANAGEMENT of the above Dispensary District will, at their Meeting, to be held at Page's Hotel, Newbridge, on THURSDAY, the 17th JANUARY, 1867, at the hour of Twelve o'clock noon, proceed to appoint a Medical Officer, duly qualified in accordance with the Order of the Poor-law Commissioners, at a Salary of £100 per annum, exclusive of Fees for Registration and Vaccination.

The Gentlemen appointed will be required to reside in the town of Newbridge.

Applications from Candidates who are required to be in attendance, accompanied by testimonials, &c., will be received by me up to Twelve o'clock on the above day.

THOMAS H. MEADE, Hon. Sec.

Newbridge, 2nd January, 1867.

**Apothecaries' Hall of Ireland, 40 Mary-**

street. The following new Medicines and Preparations are manufactured in the Laboratory on the premises, and a supply constantly on hand:—

Sulphite of Magnesia, Syrup of Phosphate of Iron, Quina and Strychnia, Chlorate of Quina, Perchloric Acid, Concentrated Solution of Chlorinated Lime, Carbolic Acid, Pure and Crude—(the latter free from Sulphuretted Hydrogen)—Permanganate of Potash; and the other Disinfectants now in use.

CLINICAL LECTURES  
DELIVERED IN  
STEEVENS' HOSPITAL,  
TOGETHER WITH  
OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

OBSERVATIONS ON THE TREATMENT OF THE DIABETES  
MELLITUS.\*

(Continued from page 52.)

In the case just related, the cessation of accustomed perspiration, and the perpetual chillness, were symptoms which strongly indicated the necessity of remedies capable of recalling the suppressed and interrupted functions of the skin. The patient had enjoyed perfect health until the period of his long exposure to wet and cold. His habits of life had always been temperate; there was nothing, except the circumstances of his voyage, which could in any manner account for the disease.† It ought likewise to be noticed that, *previously* to the perception of any other symptom, the coldness of the surface and dryness of the skin existed. These symptoms did not at any time disappear until, after the repeated use of the vapour-bath, the functions of the skin were beginning to be restored; from the moment the pores were opened, the sensation of chillness ceased. How far the tincture of opium may have conduced to the efficacy of the remedy, it is not easy to determine. Once, after the opiated vapour-bath, the patient's sleep was much more heavy and protracted than usual. Such an effect might have been produced by the opium ascending with the vapour; this, however, is by no means certain. To establish the value of opium thus externally applied, numerous observations are necessary. Having once succeeded in bringing out a moisture upon the surface, it yet remains—a task of no small difficulty and importance—to maintain a permanently relaxed and moistened condition of the skin. To attain this desirable object, exercise and warm clothing, as remedies, claim peculiar attention. Riddal had not been working in the garden two days when the urinary secretion was diminished to one-third of its ordinary quantity; this change was accompanied with a corresponding mitigation of every other morbid symptom. With patients in the better ranks of life this remedy (which I conceive to be one of high importance) is practicable at every season of the year. Active exercise on horseback will excite perspiration, without producing fatigue.‡ To this remedy the patient will, at first, be extremely averse; he will himself, however, soon discover its value, and be inclined to persevere in its use. It will require a very considerable effort to overcome the inertness and languor which hang over the diabetic patient. If, however, the remedy be

\* Dublin Hospital Reports, vol. iii., page 431, 1822.

† The same cause in different individuals, according to their several predispositions, produces very different effects. I had under my care in the hospital a man who sailed in the same vessel, and was exposed to the same causes of disease as Riddal. He, in like manner, for some time afterwards, felt cold and chilly, but the disease with which he was attacked was an intermittent fever. It is remarkable that this man's ague, though it had resisted bark given in the very largest doses, yielded easily to a moderate course of mercury, aided by opium and antimonial wine. In addition to these remedies the Pediluvium was used every night, and free perspiration established. It may be worthy of remark that this person had been, nineteen years before, affected with the same disease, at a period when intermittent fever prevailed very generally at Drogheda and in its vicinity.

‡ It is important that the convalescent from the diabetes should not suffer even a single day to elapse without engaging in such exercise as shall determine powerfully to the skin. The advantages of exercise may be obtained in a variety of ways, such as in walking, dancing, fencing, &c. The patient who is fond of riding may procure that enjoyment in a riding-school or other similar enclosure, even during the severest weather.

so managed as to determine powerfully to the surface, it will be accompanied by a degree of vigour and exhilaration sufficient to insure its being for the future persevered in; not so with blood-letting, opium, emetics, animal diet, and other remedies usually resorted to. The proposed plan of exciting diaphoresis by means of muscular action, is well calculated, not only to check the progress of the disease, but also to obviate the liability to a relapse. This is a matter of no small importance; for it rarely happens that a fully-formed diabetes (I mean that in which the urine is decidedly saccharine) is radically and permanently cured.

This case shows, that a temporary diarrhoea diminishes the quantity and alters the quality of the urine. I have at present under treatment in the hospital a man named Hughes, labouring under the diabetes, for whom the following purgative was directed:—R. Pil. colocyn. gr. xii.; Ol. croton. guttas ii. M. Fnt. pilulæ sex; sumatur una tertîa q. q. horâ, docep alvus soluta sit. This poor man, concluding that he could not take too much of a good thing, swallowed the whole at once: he was largely purged, but not nauseated; for several days afterwards his bowels remained tender and painful. So long as the diarrhoea continued, the urine was scanty and high-coloured; hence it would appear that, in the treatment of the diabetes, daily purgation should not be omitted. Sufficient diaphoresis once established, the bowels will easily yield to mild purgative medicines. From this case we also learn, that the sweating treatment ought not to be pushed too far, lest cutaneous eruption, troublesome and difficult of cure, should ensue. In Riddal's case, the exclusively animal food produced a high and dangerous fever—no uncommon consequence of such a regimen. In several of the recorded cases a similar effect was produced. In a young woman, named Galbraith, treated for the diabetes at the Whitworth Hospital by my friend Dr. Cuning, and now under my care, fever was twice caused by the animal diet. We may, I believe, with certainty conclude, that a full indulgence in animal food, while at the same time the body is not exercised, must end in the production either of some febrile disease or of local inflammation. I cannot therefore but object strongly to that mode of treatment, which would enjoin upon the patient at once a strict adherence to the animal regimen, and abstinence from exercise and bodily labour. I know not any disease in which a carefully regulated diet is of more importance than in the diabetes. The appetite is morbidly keen; its full gratification will certainly overload the stomach, and create much distress. Fulness at the epigastrium is a very frequent symptom, as also a sensation of heat and spasmodic constriction and tightness about the region of the stomach, these feelings are always increased after a full meal. In looking over the notes of several cases of this disease treated by Dr. Crampton,\* I find that in one instance, blood was vomited. In the "Dictionnaire des Sciences Médicales," an account is given of the dissection of a diabetic subject, performed by MM. Dupuytren and Thenard, amongst other morbid appearances, we find the following:—"L'estomac était extrêmement volumineux (cinq à six pintes de capacité); les vaisseaux de cet organe, très-dilatés, formaient, à la surface interne, un réseau très-rouge et plus développé que de coutume. Le duodénum, le commencement du jéjunum, et le cœcum étaient un peu plus rouges et un peu plus épais que dans l'état naturel." The fulness and tenderness about the epigastrium, as well as the appearances in this almost solitary instance of dissection, would lead us to avoid every stimulating article of diet, and restrict the diabetic patient to moderate allowances of such food as is most easy of digestion. In Gal-

\* Whilst providing materials for clinical observations on the case of Riddal, who was then in hospital, Dr. Crampton kindly furnished me with notes of several valuable cases, which fell under his observation and treatment, both in hospital and private practice. In almost all of them, there was fulness about the epigastrium or uneasiness on pressure. In all, without exception, the skin is described to have been dry, harsh, anserine, or scaly. In several, cold and wet were the immediately exciting causes of the disease. Emetics, bleedings, purgatives, warm baths, and the hepatized ammonia, were the remedies principally employed. In all, the progress towards a cure kept pace accurately with the effects produced by these remedies in restoring the functions of the skin.

braith's case, the diet consists of bread, a small allowance of meat, and a larger proportion of well-boiled rice. This diet agrees well. Her common drink is the carbonated lime-water; which, she says, appeases her thirst more effectually than any fluid she has ever taken. This patient has been much benefited by the frequent application of leeches at the region of the stomach. She has now laboured under the disease upwards of four years. An exclusively animal diet obtained, in her case, a full and fair trial. Under its use the urine was rendered less abundant, and more deeply coloured; she did not, however, notwithstanding the diminished secretion of the kidneys, gain weight, or recover her strength and spirits. Her thirst was intense; she loathed animal food. To her opium also was administered in large and repeated doses; no sweat was produced; the relief resulting from it was slight and temporary. The vapour-bath, frequently repeated, has caused heat of surface, and an aggravation of the symptoms, and has altogether failed to excite perspiration. After repeated efforts, a perspiration has at length been produced.

This was effected in the following way: For the purpose of softening the dry and thickened cuticle, the whole surface of the body was rubbed over with oil;\* the patient was then put into a warm bath, and the body washed with soap until the oil was completely removed. After this process had been three or four times repeated, a copious and general perspiration was excited. In the view of maintaining the cutaneous discharge, the Dover's powder is daily administered in small and frequently repeated doses, and the bowels kept free by means of the pil. gambog. comp. Under this treatment she is gradually gaining weight; her spirits, strength, and expression of countenance are improved; there is also a corresponding diminution in the quantity of urine; it is only now that the remedies are beginning to produce the desired effect. Her disease has been of long standing,† and is peculiarly obstinate. Her case, however, as well as that of Hughes (both of which I have now under treatment) I reserve for a future communication. It is remarkable that, in both these cases, the disease is connected with distress of mind. Hughes was in perfect health until he received a dreadful shock, in the sudden death of his only son, a fine lad of eleven years, who, whilst going on a message to his father, was caught in a mill, and in an instant torn to pieces; the poor man did not afterwards hold up his head; by degrees the symptoms of diabetes came on; and he is still low-spirited and broken-hearted.

There are not any functions in the body more closely connected and interwoven, the one with the other, than those of the skin and kidneys; by both these organs substances, either deleterious or useless, are carried off from the animal economy. When, from any cause, the secretion of one is increased, that of the other is proportionably diminished. They seem each capable of performing an action vicarious to the other; whence it would appear highly probable that very similar substances are expelled from the system by both these outlets. It is also remarkable that medicines, derived either from the vegetable or mineral kingdoms, possessed of diaphoretic properties, may, by a slight alteration in the mode of exhibition, be rendered diuretic. So closely connected are these two functions, that the same substances will act as excitants both to the one and to the other. This connection between the skin and the kidneys did not escape the notice of the accurate author of the *Cyropede*, as appears from the account he gives of the manner in which the Persian youth were educated: ‡ he notices their moderation in food, and their "working

off" (*εκπορεύσθαι*) that food by exercise. He speaks of it as a disgrace to be seen retiring for the purpose of making water, or of any other evacuation; this, he observes, could not be the case, unless they made use of a restricted diet, and *consumed the humours by exercise*. Here is accurately described the plan of treatment by which the excessive flow of urine in the diabetes will most effectually be checked. By acting powerfully upon an organ, which is more intimately connected with the kidneys than any other in the body, the physician is furnished with a weapon capable of restraining, and even subduing, this formidable disease.

The remark has been made, that England, above all other countries, is that in which the diabetes is most prevalent. It has been attempted, in various ways, to account for this. A very general explanation is, that in these countries the disease is excited by the habit of drinking tea, punch, and other diluting fluids; but were this the real cause, the disease should abound still more in France, where the natives freely indulge themselves in the weak and acid wines of the country. Potatoes, the reputed cause of so many ills, have not been suffered to escape without blame; but I more than doubt that this disease has ever been caused by a vegetable diet; even were this the case, it surely would not account for its predominance in England, the country in which of all others the largest proportion of solid meat is consumed. No peculiarities of regimen will, I am persuaded, account for the greater prevalence of this disease amongst us: the true cause is of a very different nature, and may, I think, be traced to the fact that, diseases arising from atmospheric vicissitudes are more numerous in England than in any other country; amongst these the diabetes may be classed. Suppressed perspiration, especially if connected with distress of mind, fear and apprehension, does more frequently than any other cause, give rise to this complaint. It would be interesting to ascertain whether the disease be rarely or frequently found in steady and warm climates—in climates where the heat of the atmosphere maintains an habitually relaxed and perspiring state of the skin. This enquiry is interesting in a double point of view, both because it would throw light upon the connection between the skin and the kidney in the diabetes; and also, should it appear (as I suspect) that the true saccharine diabetes is a rare disease in warm climates, it would lead those who can afford to travel, and who have derived benefit from medical treatment, to quit for a while a country, in which every diabetic patient, however much the symptoms may have been relieved, is continually prone to relapse. It may be, that a residence of a few years in a warm climate would completely eradicate the disease. This is an important consideration, and well worthy the attention of medical men.

In the wonderful accounts which are to be found in the works of some authors (for there are persons, who, not satisfied with the ordinary operations of nature, love to go in search of the marvellous) of the immense excess of the egesta above the ingesta, it seems to have been forgotten, that excretion by the skin is at an end. All that should have been removed by secretion from the surface of the body is carried off by urine; besides, there is scarcely any pulmonary exhalation, and the feces are almost dry: the tears and saliva are scarcely secreted; even ulcers cease to discharge; so that all the humours of the body are passed off by the kidneys; the urgency of the thirst calls for a large and continual supply of fluids: the patient drinks more abundantly than his medical attendant is aware of. If then all these circumstances are unitedly taken into the account, it will, I imagine, be found, that there is not such an immense disproportion between the ingesta and egesta, as some would lead us to think. That the more solid particles destined for nutrition are carried off by urine, is certain. It is one of the essential characters of diabetic urine—whether animal or vegetable diet has been used—that the

\* This process of oiling the surface was used by Dr. Rollo in the view of preventing cutaneous absorption: the object was unnecessary; the effect produced, in softening and relaxing the cuticle, salutary.

† This girl observed her hair to fall at the same time that the thirst, appetite, and flow of urine became inordinate. About three months ago her hair was shaved off. Since that period it has grown to the length of about an inch.

‡ Καὶ νῦν δὲ ἐπι ἐμμένει μαρτυρία καὶ τῆς μετρίως διαίτης αὐτῶν, καὶ τὸν ἐκπορεύσθαι τὴν διαίταν. Λίσχρον μὲν γὰρ ἐπι καὶ νῦν ἐστὶ Πέρσαις καὶ τὸ ἀποπτύνει, καὶ τὸ ἀπομύττωσθαι, καὶ τὸ φύσης μισοῦς φαίνοσθαι· αἰσχρὸν δὲ ἐπι καὶ τὸ

ὄντα ποῦ φανερὸν γενέσθαι ἢ τοῦ οὐρησθαι ἕνεκα, ἢ καὶ ἄλλου τινὸς τοιοῦτου. Ταῦτα δὲ οὐκ ἰδύνατο ποιεῖν, εἰ μὴ καὶ διαίτη μετρία ἐχρόντο, καὶ τὸ ὑγρὸν ἐκπομύττες ἀνήλιον, ὡς ἄλλῃ ποι ἀποχωρεῖν.

specific gravity is raised beyond the standard of health ; hence nutrition is defective, and the body wastes ; there is also a degree of irritative fever, which, like hectic fever, interferes with and prevents the process of nutrition : this state of irritation in part accounts for the great value of opium in treating the diabetes.

Dr. Prout suspects that the urine is albuminous before it becomes saccharine ; this may be true ; and it is a fact important to ascertain, as the knowledge of it might enable the practitioner to meet the approaching evil, and prevent the full development of the disease.

Dr. Rollo mentions the case of a female, in whom habitually, and whilst in apparent health, the urine was insipid at one o'clock, after dinner saccharine, and natural in the evening. From this it appears probable, that however completely a diabetic patient may appear to be cured, the urine will ever after retain a slightly saccharine impregnation.

In a case which I lately treated, there was exhibited in a remarkable manner the power possessed by the vapour-bath of diminishing the urinary secretion. The patient to whom I allude laboured under pulmonary disease, the result of frequent and neglected colds : he had lived in habits of intemperance, and almost daily intoxication. In addition to the pulmonic symptoms, he was harassed by an intense thirst : he drank many quarts of cold and acidulated water in the course of the day ; his skin was scaly and dry ; the mucous membrane of his mouth parched and intensely florid ; the secretion of apparently healthy urine amounted habitually, in the course of twenty-four hours, to not less than sixteen pounds. For him the vapour-bath was directed. Though weakened and much emaciated he bore the bath without inconvenience : an abundant and general perspiration was produced ; the thirst ceased ; and the urinary secretion fell almost immediately to its ordinary standard.

The cure of a disease, so obstinate and fatal as the diabetes mellitus, ought never to be entrusted to any single remedy. A regular and systematic plan of treatment should always be adopted : and though the exciting and maintaining of an abundant and general diaphoresis, be the essential—the indispensable part of the treatment ; yet this measure, important as it is, should not supersede the adoption of other remedies : which, though comparatively of inferior value, are yet, by their combined action, capable of effecting much toward the removal of the disease. I shall conclude, then, by a brief enumeration of the several remedies, which by their united operation afford the best prospect of restoring the diabetic patient to the enjoyment of health.

First : When the disease is recent, and the strength not too far exhausted, blood-letting is a measure which should never be omitted. It may be necessary more than once to open a vein : the effects produced by the first operation will enable the practitioner to judge of the necessity of its repetition. Venesection will powerfully promote the action of those diaphoretic remedies to which principally the cure of the disease must be committed. Hughes was greatly relieved by a bleeding from the arm : it was followed by the tepid-bath ; an immediate and decided impression was made upon the disease.

Secondly : Leeches at the epigastrium will be found in many cases a valuable remedy. In the case of Galbraith, the local bleeding was attended with considerable advantage. When there is a feeling of internal heat, and the epigastrium is tumid and tender, and when there is a sensation of fulness, with what the patient describes to be "a gnawing feel about the stomach," the application of leeches at the epigastric region will be attended with considerable benefit.

Thirdly : The bowels of the diabetic patient should every day be freely evacuated. Copious alvine discharges have the effect of diminishing the urinary secretion : this is proved by the effects of the croton oil in the case of Hughes, and of the colocynth pill in that of Riddal. It may be desirable in some instances to excite a temporary diarrhoea by the action of purgative medicines. It will be necessary,

however, to proceed with caution ; since any considerable derangement of the bowels will not fail to increase the severity of the disease. The safest course to adopt will be that of evacuating sufficiently, without violently purging the patient.

Fourthly : the diet of those who labour under the diabetes should be arranged with the utmost care. The process of digestion is rapidly and imperfectly performed : the stomach easily oppressed and overloaded. Food should, therefore, be given frequently, but always in very moderate quantity—in a quantity far short of that which the craving desire of the stomach seems to demand. It would, I am sure, greatly conduce to the patient's recovery, could he be prevailed on to restrict himself to a certain portion of food at each meal, and not on any occasion to exceed the number of ounces prescribed. The articles of diet which I have found to agree best, are broiled meat, soup, bread, well-boiled rice, and gruel. Fish, from its tendency to create thirst and drowsiness, I cannot recommend : potatoes I have observed frequently to disagree. As an ordinary drink, I have not known any allay thirst more effectually than the carbonated lime-water. Beef or veal tea, milk with lime-water, and wine very much diluted, have also appeared to agree well.

Fifthly : Every effort must be made by remedies acting directly upon the skin to excite that organ, and reproduce its suppressed functions. The vapour or tepid bath must be used perseveringly every day, or even twice a-day, until the vessels of the surface are excited, and the cutaneous secretion restored. The frequent immersion of the feet in warm water will sometimes succeed, even after the failure of more powerful remedies. At the same time the pulv. ipecac. comp. should be given in doses of eight or ten grains every third hour, till perspiration shall be fully established. A perspiring state of the surface should afterwards be maintained by means of warm flannel worn next the skin ; by active exercise ; and finally, if practicable, by a long residence in a warm climate. When the patient begins to regain strength, and appearances of amendment become decided, the cold bath will prove an useful tonic, and an excellent cutaneous stimulant. Under this treatment the patient will, if I mistake not, gradually recover his spirits and mental vigour, regain flesh and strength, find his thirst abate, his appetite grow less keen, and his urine improve both in quantity and quality. On the patient's own resolution and perseverance, much of the cure will depend : he must fully co-operate with his medical attendant. It would not be easy to name a remedy less irksome to the individual, or less injurious to the constitution, than daily and active exercise ; and if any remedy can diminish the liability to relapse, this, I am persuaded, will. The patient should, therefore, be particularly warned of the danger of laying aside too hastily a plan of treatment, which tends at once to remove the symptoms of the disease, and to guard against the danger of relapse.

## Hospital Reports.

MERCER'S HOSPITAL.

HEPATIC ABSCESS SIMULATING ABDOMINAL ANEURISM.

By WILLIAM MOORE, M.D., M.R.I.A.,

PHYSICIAN TO MERCER'S HOSPITAL ; VICE-PRESIDENT OF THE COLLEGE OF PHYSICIANS, AND LECTURER ON PRACTICE OF MEDICINE, ETC., ETC.

GENTLEMEN,—Most of you whom I see around me must remember Maria N—, who was a patient some time since in this hospital, and who presented a type of disease of not very common occurrence and certainly of unusual interest. The details of the case I shall recapitulate for you :—

Maria N—, aged 28, a dressmaker, of admittedly intemperate habits, was brought to the hospital in June last. About ten days before she applied for admission she felt

what she described as a "throbbing lump" in her stomach. She also suffered from palpitation, short dry cough, constant pain in the back, which radiated towards the stomach, from rigors, night sweats, obstinate vomiting, especially after eating, and from total loss of appetite.

On examination, we found a tumour about the size of a hen-egg occupying the epigastric region. This tumour pulsated, and on applying the stethoscope over it a bruit could be heard which was lost in the upright position. Moreover, place the patient in what position you pleased, the pulsation was continuous. To test this we made the patient get on her hands and knees, still the pulsation remained, and this is a point worth your especial attention, for, as I hope to show you by-and-by the presence or absence of pulsation in this position is an important link in the differential diagnosis between hepatic abscess and abdominal aneurism. However, to resume, there was dulness over the hepatic region generally, and over the anterior and inferior region of the right side, where respiration was indistinct. The menstrual functions were regular, and the bowels free. After the patient had been a few days in hospital jaundice supervened. Now, the treatment we employed in this case was the effervescent saline mixture, with hydrocyanic acid, with the view of relieving the great irritability of the stomach. Ice was applied over the tumour, which was afterwards painted with a strong tincture of iodine, whilst five-grain doses of iodide of potassium were given in decoction of taraxacum three times a-day. Under this treatment the tumour, at the end of a month, had sensibly diminished, and the pain in the back and other symptoms had abated. At the end of six weeks the tumour could not be felt, and the girl's health was so much improved that she left the hospital, a faint tinge of jaundice only remaining.

Now, this patient was sent to hospital supposed to be suffering from abdominal aneurism, and, I confess, the first look at the case inclined me, as it did several gentlemen to whom I showed it, to arrive at the same conclusion, but a more careful examination shook this belief. As regards the pain in the back and jaundice, both these general symptoms might tally with abdominal aneurism; so might the vomiting and irritability of the stomach if the enlargement of the vessel came in contact with that viscus; but, in addition, we had rigors and night sweats, symptoms never found necessarily associated with aneurism, and which were of especial value as pointing to the formation of matter somewhere.

Next, as to the especial character of the tumour itself. It was about the size of an hen-egg, slightly flattened, and occupied the situation usually allotted to aneurisms of the abdominal aorta, whilst its pulsation was diastolic and eccentric. These special points, for so far closely resembling the signs of aneurism, tended to embarrass the diagnosis, and the presence of a bruit in the supine position, which became lost in the upright, still further obscured the case.

But there was one point which came to our relief, and that was the partial modification of the impulse by pressure on the tumour towards the right side. If with this important sign we had found absence or diminution of the impulse when the patient was placed on her hands and knees, the diagnosis would have been comparatively clear, for you will readily see that when a patient is placed in this position, an hepatic abscess or other non-adherent tumour falls forward from the aorta, and thus pulsation is lost, but in this instance there must have been some adhesions between the under surface of the liver and the great vessel which afforded a medium of pulsation. After some time, and giving due weight to the character of the constitutional disturbance in general, and to the modification of the impulse by pressure in particular, we arrived at the conclusion that the case was one of hepatic abscess, occupying the left lobe of the liver.

You may naturally ask me how did the contents of the abscess, which were of no trifling amount, disappear so stealthily as they did, and so favourably, and is this the usual way in which hepatic abscesses are disposed of?

The abscess may make its way through the thoracic or abdominal wall, in the latter case it usually points below the ensiform cartilage of the sternum, or it may point through an intercostal space, and eventually burst.

The abscess may burst to the stomach, and if so the rupture is followed by purulent vomiting or pus in the dejections or both. Should the abscess open into the intestinal canal, the symptoms are usually ill-defined, but the patient's attention may be arrested by the sudden subsidence of pain, and rupture into the peritoneum is in almost every instance followed by speedy dissolution. On the other hand, should the pus make its way into the bronchial tubes, this contingency is usually preceded by symptoms of pneumonia, as dulness on percussion, bronchial respiration, and rusty sputa, and when the rupture *actually* occurs copious purulent expectoration follows, even pure bile may occasionally be spat up. Again should the right pleural cavity be the receptacle of the abscess, the symptoms of ordinary empyema are set up, but rupture into the pericardium is an event of very rare occurrence, and when it has occurred, has been attended with a rapidly fatal termination.

Now, in the case before us, we have no positive proof that the abscess took any of these courses above-mentioned; it might have opened into the intestinal canal or bile duct, and thus have been disposed of, but if so, I am inclined to think there would have been some more sudden and decided remission in the symptoms than what took place, and I think the pus in the dejections could scarcely have escaped us.

To be plain with you, I am at a loss to account for the exact *modus operandi* by which so gradual and favourable a termination was brought about in this unpromising case. Frerichs tells us that under favourable circumstances the suppurative process is arrested, the pus undergoing a retrograde metamorphosis, and thus the abscess gradually is reduced in size and cicatrizes, the symptoms steadily disappearing, and this seems to me the most feasible way to account for the disposal of the abscess in the present instance.

## ST. MARY'S HOSPITAL.

### FATTY TUMOUR OF THE NECK; OPERATION.

Under the care of Mr. HAYNES WALTON,

SURGEON TO THE HOSPITAL, AND TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL.

THE points of practical interest to surgeons in this case are two—the diagnosis and the manner of operating.

The tumour was situated at the side of the neck, just above the clavicle, between the mastoid muscle and the trapezius. It was large enough readily to attract notice.

The patient was twenty-five years old. The history merely told that a couple of years ago a swelling was noticed in the neck, and about the same time hard lumps appeared under the arm on that side. The tumour grew, while the lumps disappeared.

There had been difficulty in diagnosis, for the woman had been to two public institutions, and at both it was supposed that the tumour was made up only of enlarged cervical glands. Mr. Haynes Walton decided otherwise. He considered it to be a fatty tumour, and determined to remove it.

When the patient was brought to the operating theatre, Mr. Walton drew the attention of the spectators to the physical characters of the disease, and said:—"This is a case in which I can well understand that there might be a difference of opinion as to what the tumour was made up of. From a hasty examination, no doubt, most persons would suppose that they were touching merely lymphatic glands, and most certainly I should come to the same conclusion if I were to examine only a part of the mass. But, after I have scrutinized every portion of it, felt its general looseness, ascertained that the lumps are softer than glands would be, and taken into consideration that the tumour is increasing from below upwards, I say that it is fatty." Mr.

Walton ascertained the exact position of the jugular vein so as to avoid wounding it, made an incision in the long axis of the tumour, and cut through the skin. His diagnosis was accurate. Out gushed a lobule of loose yellow fat, a part of a true fatty tumour or lipoma. As he was dissecting in a very dangerous region he proceeded slowly, and laid open the capsule of the tumour to its entire extent.

As the capsule was adherent, dissection was required over the whole surface. None of it could be torn away, as may commonly be done. During the last stroke or two of the knife, two arteries were divided, and quickly secured by ligatures.

These remarks were made after the operation:—"Of course, gentlemen, I am gratified in being able to verify my diagnosis. I proceeded very slowly at first until I was able to ascertain the character of the tumour, because had I not seen fat I should have desisted, but as soon as a yellow lobule shot out, I went on quicker and with more confidence. Because everything has gone on smoothly today, you must not suppose that the operation was a very easy one, or that it was unattended with risk. I was dissecting deeply among very intricate parts, surrounded by vessels of large magnitude and of importance, for the ramifications of the tumour were many and deep. I wish to tell you the secret of my success, for if you know this you may act as well as I have done, but if you are ignorant of it you may get into great difficulty in attempting a like thing. I so conducted my dissection that every stroke of the knife told against the tumour; in fact, the edge of the instrument was always toward its axis, and not away from it, so that I never divided anything I did not see, and I could not divide anything that did not come into the tumour or go out of it, so that if I had had blood-vessels in the closest proximity to the tumour, so long as they did not penetrate it, they were safe. If the point of the instrument had been once away from the surface of the tumour and out of sight, I might have divided anything. You saw that two small vessels were divided at the very last stroke of my knife. These were the proper vessels of the tumour—the vessels of nutrition—and as they were cut superficially they were very quickly secured by the forceps. By following this important rule, I have removed a large tumour from among intricate relations, without ever seeing any muscular tissue, or dividing any blood-vessels unconnected with the morbid growth."

The wound was brought together by sutures, and at this time, just a week after the operation, it is nearly quite healed.

## Foreign Medical Literature.

### TWO CASES OF ABSCESS IN THE ANTERIOR ABDOMINAL WALL, IN CONSEQUENCE OF THE PRESENCE OF A FOREIGN BODY WHICH HAD BEEN SWALLOWED, AND WHICH PERFORATED THE INTESTINAL CANAL.

Communicated by Professors SANTESSON and KEY.

Translated from the *Hygiea* for June, 1866,

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A., HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

DALKULLAN STINA LARSDOTTER, aged 31, was admitted into the Surgical Division of the Seraphim Hospital on the 23rd October, 1865, for a tumour of doubtful nature, situated in the anterior abdominal wall.

Respecting her previous state she gave the following information:—She had always enjoyed excellent health. She

was delivered on the 4th April, 1865, of a living boy, which died at the end of fourteen days. Her labour was difficult; it lasted four days, after which she was obliged to keep her bed for a fortnight. After this time she recovered her strength, and soon felt perfectly well. The secretion of milk ceased gradually of its own accord; menstruation was shortly re-established, and subsequently went on regularly. Towards the close of the following August the patient began to observe a hardness in the right side of the abdomen, for which she could not in any way account. At the end of a week the swelling had attained the size of the open hand; was flat, with the surface looking anteriorly rather convex; it was superficially tender to the touch, and caused such considerable pain that the patient was deprived of sleep, appetite, and capacity for work. After about three weeks, during which time she emaciated greatly, several small red elevations appeared over the hard part; these were very painful, opened at the end of five or six days, and discharged a considerable quantity of pus and blood. This occurred in the last days of September. After this all pain and tenderness disappeared; the patient could move about with tolerable ease, and was able to attend to her avocations. But as at the end of some weeks the tumour began again to increase in size, causing inconvenience at work, she sought for, and obtained admission into hospital.

The journal contains the following report of her state on admission:—The patient is of ordinary stature, rather emaciated, sallow complexion, muscular system flaccid. Heart and lungs in normal condition. Pulse full and even, about 80 in the minute. Liver and spleen not enlarged. Digestive organs in good order, except that the bowels have latterly been rather torpid. Tongue clean and soft. Appetite and sleep excellent. On examining the abdomen a swelling of nearly round form, extending from the symphysis pubis upwards to about two or three inches above the navel, is observed in its anterior wall. The swelling in shape resembles most nearly a loaf, with considerable convexity on its anterior surface; it occupies principally the right side of the abdomen, at a distance of a finger's breadth from Poupart's ligament and the anterior spine of the ilium, extending with a rounded border to the left, about 2½" beyond the median line. To the touch it is firm, almost hard; follows the abdominal wall in its movements, and is so well defined that its outer margin can almost everywhere be raised and grasped in the hands through the doubled integuments. The latter are so tense and drawn in over the convex surface of the tumour, that they cannot be lifted up in folds. On stretching the abdominal muscles the recti are observed to extend behind the tumour, or to be lost in its inferior part. When the abdominal muscles are relaxed the tumour becomes more movable, and as it were, lighter. Over the whole tumour there is a distinct intestinal sound on percussion, though rather dull in comparison with that of the surrounding parts of the abdomen. On the surface of its superior arch, to the right of the linea alba, are some fistulous, ulcerative openings, partly communicating with one another, of from half a centimètre to a centimètre in transverse diameter, filled with loose granulations, and secreting abundantly bloody pus. Through these openings a probe can be introduced to a depth of nearly 1½ inches, at a right angle to the abdominal wall; in the horizontal direction it can be passed somewhat further around. The cavity in which the probe is moved seems irregular, here and there divided by cross and transverse imperfect partitions, and for the greatest part filled with a loose granulating mass, which is easily set bleeding. The skin over the whole tumour is strongly hyperemic, in spots reddish blue and discoloured, especially about the ulcerative openings already mentioned, and is very tender to the touch. In other respects, when the patient lies quietly on her back, the tumour causes neither pain nor any inconvenience.

On examination *per vaginam* the uterus is felt completely involuted, free and movable; no change of position; no depression or abnormal fulness of any part of the vagina. Nowhere is there any tenderness. Examination through

the rectum indicates nothing morbid. The urine is clear, of ordinary colour; its specific gravity is 1.023; its reaction is acid; it contains chlorides in abundance, but no albumen. Microscopic examination exhibits nothing abnormal.

Of what nature, now, was this tumour, and whence did it proceed? It was evident that it pertained principally to the abdominal wall, and that this was in its entire thickness implicated in the swelling. That the severe pains in the place, which the patient had experienced in the month of September, were caused by peritonitis, was very probable, but whether this had given rise to adhesion between the abdominal wall and the omentum or intestine situated within it, could not with any certainty be decided, and it must therefore be left an open question whether the tumour proceeded from one or other of the abdominal viscera, or stood in any closer or causal connection with these. Thus much was, however, certain, that even if this were the case, such a state of things did not produce any remarkable obstruction to the free movement of the intestines, or to the passage of their contents. Moreover, if the patient's statement could be relied on, the tumour had existed *before* the symptoms of peritonitis. Neither could she assign any cause. The only circumstance in her history which could possibly be brought into connection with the disease for which she had now sought admission to the hospital was the labour which occurred in April. But, although this is stated to have been severe, the patient nevertheless asserted that, from the beginning of May to the latter half of August, she had been in all respects perfectly well; and the examination of the uterus and its appendages, made immediately after her admission, did not indicate anything morbid in these parts. A limited peritonitic effusion, encysted between the abdominal wall and the omentum, with perforation of the former after a secondary phlegmon (*per contiguitatem*) in the abdominal integuments, also deserved consideration; but the question still remained unanswered—What was the cause of the primary swelling? Moreover there were one or two circumstances which did not fully agree with or find their explanation in such an assumption; in the first place, the unusual situation of the tumour towards the anterior abdominal wall *away from* the cæcum, iliac fossa, kidney, liver, and other parts, which usually serve as the starting point of such a process. Next the unusual and peculiar fact that, under such circumstances, the pus made way for itself through the abdominal wall in one of its strongest points—over and to the side of the rectus muscle on the right side—instead of, as usually occurs, sinking down into the iliac fossa or inguinal canal, pressing forward through this or in its neighbourhood, or perforating one or other of the adjoining intestinal loops. To a congestive abscess the disease had not the most remote resemblance, as no source of any such was anywhere discoverable. In a word, the cause of this in many respects remarkable swelling must for the present be left undetermined, and we were therefore compelled to make our treatment of the tumour and abscess purely symptomatic, without being able more nearly to decide the origin and proper nature of the affection.

Cataplasm to the tumour. The occasional use of decoctum frangulæ to promote the action of the bowels. At the end of a month, that is towards the close of November, the swelling had considerably diminished, the secretion from the abscess was more scanty than before, most frequently it was of a thin serous nature, not unusually mixed with some blood.

On the 25th of November it was noted: the patient is feverish, after having in the forenoon had slight shiverings continuing for half an hour. There is slight tension and tenderness in the epigastric region, but not in any other part of the abdomen. There are no thoracic symptoms. The pulse is 92. The urine contains a quantity of urates, but no albumen. The fever continued on the following days, though it was slight, and attended with complete remissions in the forenoon. Irregular transitory shiverings occurred from time to time. On the 1st December pain

was felt in the left hypochondrium, extending thence down over the hip and into the iliac fossa—most perceptible on moving the left leg—without any material change in the skin or subjacent organs being discoverable on examination. In addition there were symptoms of a slight gastric catarrh, which, however, as well as the pain and fever just mentioned, shortly yielded to the use of tonics, with quinia and morphia at night, so that during the latter half of December and the first week in January, 1866, the patient felt comparatively well. The tumour steadily diminished, until, according to the note in the journal for the 13th January, 1866, it could no longer be considered such; the abdominal integuments could now be grasped in a fold in the place where the tumour had been situated; only two of the openings of the abscess still yielded a slight seropurulent discharge; the others had been healed.

Towards the middle of January a change took place in the patient's state. Her appetite ceased; her tongue was furred; she complained of a bad taste in her mouth; she had daily, and sometimes several times a day, recurrent shiverings, followed by fever, headache, and colliquative sweating. The pulse was constantly almost, sometimes above, 100. Tenderness in the epigastrium and over the liver, the left hypochondrium, and the lumbar region. Occasionally hiccough and nausea. Tendency to cough, with a feeling of stitch in the left side. Physical examination elicited a dull sound on percussion, a feeble and remote respiratory sound with diminished pectoral murmur around the lower lobe of the left lung, up to about the level of the angle of the scapula. There was no dyspnoea. Corresponding to the two inferior ribs there was considerable tenderness on pressure, and the whole region over the spleen and down to the posterior half of the crest of the ilium appeared a week later somewhat swollen. That suppuration was taking place, could not be doubted, but it was more difficult to determine its starting point and proximate cause. Thus much, however, appeared to be clear, that it was not in any direct connection with the former swelling in the anterior abdominal wall, which had now entirely disappeared, and upon the integumental covering of which merely a couple of superficial, small ulcerous surfaces still uncovered with epidermis remained to mark the localities of the former fistulous openings. No fluctuation could as yet be discovered; but on one of the last days of January, that is about three weeks after the change for the worse took place, such was felt over the two inferior ribs, about one and a-half inches to the left of the spine. In this place an incision was now made, from which about a pound and a-half of a sero-purulent, rather bloody fluid was discharged. On the sides and in the bottom of the wound were seen lumps of the fascia lumbodorsalis and of the musculus sacro-lumbalis. In the direction forwards and upwards a probe could be introduced about four or five inches from the opening made, but not in towards the spine, which in other respects exhibited nothing morbid. No denuded bone could anywhere be discovered.

During the ensuing twenty-four hours an almost equally large quantity of similar pus was spontaneously discharged through the wound. On the 1st February it was noted that the discharge was considerably diminished; it was of the same nature as at first, but without blood. The dull sound on percussion over the lower part of the left lung had disappeared. The respiratory sound and the pectoral murmur were nearly restored. The tenderness over the two inferior ribs was quite gone.

From these circumstances, collated with the symptoms already noted, it was evident, as had appeared even on the first examination of the left side of the thorax to be most probable, that the dull sound on percussion, and the remoteness of the respiratory murmur depended not on any effusion in the pleura, but on an encysted exudation, possibly an abscess, situated beneath the diaphragm, pressing the latter upwards, hindering its descent, and so preventing the lung from filling and extending downwards; whence this exudation or this abscess directly proceeded, it was more difficult to decide, for the place where the purulent col-

lection afterwards presented, was equally in favour of a retro-peritoneal abscess resulting from perinephritis, and of an abscess around the spleen—a diffuse purulent peritonitis. The symptoms referable to the diaphragm and stomach—the hiccough, nausea, epigastric tenderness—however, make the latter assumption the more probable.

The secretion from the abscess was during the following three weeks extremely inconsiderable, and the tenderness in the left hypochondrium had entirely disappeared. The patient's general state was comparatively better than before, but her emaciation was considerable, her appetite was variable and most frequently she had none; the tongue was furred, while rigors, varying in intensity, and followed by most frequently short and slight reaction, occasionally occurred, at intervals sometimes of one, sometimes of several days.

The pulse was, however, during the whole time, in addition to weakness proportionate to the state of the general strength, quicker than natural, about 100; towards evening it was still higher. The bowels were irregular, usually torpid. On the 20th February, diarrhoea supervened with copious watery stools, which, with an occasional interval of twelve or twenty-four hours, afterwards continued, especially at night. There was no tenderness or pain in the abdomen or anus. Suspecting the possibility of perforation of the intestine from the abscess, inasmuch as no remedy seemed to restrain the obstinate evacuations, the latter were examined, but exhibited no admixture of pus, gangrenous fragments or other unusual constituents. Their appearance was like that seen in intestinal catarrh with clear semi-transparent mucous masses from the follicles of the large intestine; they were pretty strongly tinged with bile. The patient's strength, which had already been considerably diminished, sank rapidly under this symptom. Over the posterior portions of both lungs, copious, loose, and rough râles were heard. The patient did not complain of pain or tenderness anywhere; only when the attacks of diarrhoea were very frequent, did she towards the close complain of smarting and burning when at stool. After languishing for some time, and without the accession of any new symptoms, she died at two o'clock P.M., on the 4th of the following March, being the thirteenth day after the setting in of the diarrhoea.

Dr. Key communicated the following respecting the changes met with on post-mortem examination:—

The body is extremely emaciated. There is slight œdema of the lower extremities, particularly in the left. On the left side of the spine is found, in the upper part of the lumbar region, an opening of one and a-half inches in length, leading into an irregularly ramifying abscess, which, throughout a tolerably great extent, undermines the skin. Upon opening it the abscess is found to be continued by some slender concurrent canals through the muscular structure in a direction upwards to the tenth and eleventh ribs, which near their angles are each on the under edge through a small space denuded, presenting a tolerably smooth and even surface of bone, with greatly softened periosteum about it. Beneath the two denuded margins of the ribs a probe can be introduced for its entire length into the abdominal cavity. On the inferior half of the right side of the anterior abdominal wall, from the level of the navel down to the crest of the ilium and Poupart's ligament, are seen several small reddish grey crusts, and the skin cannot here be drawn over the muscular structure. On dissecting it away it is found to be connected with the muscular wall itself by a firm, sclerotic, and in greater part slate-grey connective tissue, in which are found here and there small islands of the original paniculus adiposus. Here and there are small foci filled with a whitish grey, friable earthy mass (half dried pus). On cutting through the abdominal wall in an oblique direction from the umbilicus out to the anterior superior spine of the right ilium, both the muscles and fasciæ are in general found of a steel-blue colour; the former traversed by thick, sclerotic filaments of connective tissue, on which account the different layers cannot be separated. About midway between the umbilicus and the spine of the ilium, is found in the muscular wall a sinuous abscess, about the

size of a pigeon's-egg, containing a black pin, bent nearly at a right angle. The abscess, which is about two inches in length, is connected by a couple of slender passages, with as many of the subcutaneous foci already mentioned. Corresponding to the extent of the abscess a loop of the ileum is attached on the inside of the abdominal wall, by means of extremely thick and strong adhesions of a slate or reddish grey colour. The abscess itself, which in its middle portion lies in the muscular structure, passes both at its upper and lower extremity not merely into the peritoneum, but perforates this membrane, and is continuous, by means of adhesions, with the intestine. Inferiorly it ends in these adhesions, but superiorly a probe can be introduced from the abscess into the very calibre of the attached intestinal loop. On slitting up the intestines, several small dark blue spots are found, through an extent of two inches, on the mucous membrane of the most strongly adherent portion. In one of these spots we meet with an oval ulcer, 6 mm. (.23622") in length, which perforates the mucous membrane, the latter being, through a considerable extent, undermined about the ulcer. The edges of the ulcer are slightly swollen. The muscular coat, which forms the fundus of the submucous abscess, is perforated by a hole of about the same size as that in the mucous membrane, and this opening leads directly into the upper extremity of the abscess in the abdominal wall already described, in which the pin lay.

On closer examination of the other dark blue spots, in number eight, they are found to have in general an extended transverse direction. One of them represents precisely the form of a pin. With a length of 19 mm. (.74803") it is only a little broader than the pin, and exhibits no loss of substance. It seems as if the pin had been driven in under the mucous membrane, but again set free. In one of the spots the mucous membrane is gone, terminating at the periphery in tolerably sharp and not swollen edges, which are attached to the dark fundus of connective tissue. In another the same state exists, but the edges of the mucous membrane here project by some fragments over the ulcer, the fundus of which is formed of reddish black granulations projecting from the muscular coat. A smaller opening in this fundus leads into a small cavity, situated partly in, partly without, the thickened muscular coat, without communicating with the abscess in the abdominal wall. On the other spots the mucous membrane is intact. In the abdominal cavity the intestines are otherwise found in many places adherent to one another by means of whitish grey or reddish grey, rather friable pseudo-membranous new formations, and the peritoneum, both visceral and parietal, is over surfaces of various extent, covered with a similar cuticular, pseudo-membranous new formation, which in many places assumes an intensely red colour, exhibiting numerous fine, ramified, congested vessels, passing over from the peritoneum itself. The peritoneum of the small intestines is in general remarkably thick, softened and fragile. In the true pelvis the organs are attached to one another by old false membranes, some of which are firm, greyish-white, while others are lumpy, of a dark blue colour, and in a broken-up condition. In and between the lumps lies an ashy or clay-like mass. In some places the change has invaded the substance of the uterus, which on the surface in some parts presents small spots of a steel-blue colour, while in others it is penetrated by small, greyish-white, ashy foci. The rest of the uterine substance is rather sclerotic, of firm consistence, and of a whitish-grey appearance. The right tube, whose walls are considerably thickened, is thrown back, in a very tortuous state, behind the fundus uteri. At its outer extremity it is dilated nearly to the size of a pigeon's-egg, and it is filled with thick, puriform, greyish-yellow matter. The right ovary is sclerotic. The walls of the left tube also are thickened. The left ovary is as large as a goose-egg, closely studded with abscesses of various sizes, which are filled with a thick, pale, clay-like matter. On the posterior wall, and in the fundus of the recto-uterine fossa, the peritoneum is in great part hypertrophied, presenting a number of projecting steel-grey lumps. This hypertrophied condition

extends forwards in the tissue between the rectum and vagina for an extent of three centimètres. The rectal wall is here perforated by three small adjoining openings, through which the cavity of the true pelvis communicates with the calibre of the intestine. Higher up, too, corresponding about to the middle of the body of the uterus, the rectum is perforated by a hole which readily admits the passage of the little finger. On slitting up the intestine the mucous membrane is seen in the perforated parts to be in one place completely abraded, in another throughout a great extent undermined with gangrenous lumpy, not swollen, edges, lying loose over the steel-blue muscular coat surrounding the perforations. On slitting up the whole of the large intestine, the mucous membrane is found in general rather thickened, with large solitary glands for the most part burst. At the flexura lienalis the mucous membrane is abraded in spots varying in size from that of a pea to that of a hazel-nut, with lumpy, undermined, thin edges. The fundi of the ulcers are formed of a thin layer of submucous connective tissue, which is in spots of a slate-grey colour. At the hepatic flexure some similar changes are also met with, but the mucous membrane is here in general persistent, although undermined, loose, opaquely discoloured, and tubularly perforated. In one place, in the bottom of such a submucous abscess, the muscular coat is perforated by a small hole, which leads out into an abscess of the size of a hazel-nut, which, with its ashy contents, is situated in the attachment of the mesentery. About this abscess the mesentery is of a slate-grey colour, with yellowish, white, and softer striæ (purulent infiltration, half-dried.)

(To be continued.)

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, JANUARY 4, 1867.

DR. BANON, Vice-President of the College, in the Chair.

#### PRIMARY CANCER OF THE KIDNEYS; TUMOUR (MALIGNANT?) IN THE PROSTATE GLAND.

DR. FLEMING presented specimens illustrative of the above lesions, and having mentioned the previous and existing symptoms of the case connected with them, entered into the details of the morbid appearances, stated the doubts entertained respecting their histology, and alluded to the remarkable isolation of the disease in the kidneys, and the treacherous latency of its progress and development, all complaint having been referred to the bladder and its immediate locality. Hæmaturia did not present itself as a symptom throughout the whole progress of the disease, neither were there any morbid conditions of the urine to indicate its presence. The history of the case, as learned, was not as satisfactory as could be desired. The prostatic tumour did appear to be of "cystic" development, and somewhat like that of the "chronic mammary tumour" of Professor Colles and Sir Astley Cooper, as specially noted by Mr. Paget. The question was, however, debatable.

#### FEMORAL HERNIA OF UNUSUAL SIZE.

By EDWARD HAMILTON.

I am indebted to Mr. Colles for the privilege of presenting to the Society this case, which illustrates a case of femoral hernia, in which the protrusion attained an unusually large size. The patient, a female about forty years of age, was admitted last week to Steevens' Hospital, labouring under the symptoms of strangulated hernia, constipation, vomiting, tympanitis, cholicky pain, which she states to have existed for four or five days previous to her admission, so that if we recognize the distinction adopted by some surgeons between strangulated and incarcerated hernia, we should rather refer the case to the latter variety. The early history of the disease showed, that about ten

years since, she strained her right leg in leaping from a height, which obliged her to keep her bed, at which time she observed the tumour, then not larger than a walnut. She had suffered from irregularity of the bowels, but no absolute obstruction until the present attack. Repeated attempts at taxis had been made previous to her admission. She was at once attended by the resident-surgeon, Dr. Tyner, by whom the hernia was reduced after prolonged and careful manipulation, the bowel suddenly returning with a loud gurgling sound. The functions of the intestine have been perfectly restored, although a considerable mass of omentum appears still to remain in the sac. I would not think of trespassing on the time and attention of the Society with the details of a mere case of femoral hernia, but I think the size of the tumour, which, before reduction, was fully twice as large as the cast represents, suggests two or three reflections to the practical surgeon—first, how the femoral ring, surrounded as we know it is by dense unyielding fibrous structure, can adapt itself to the passage of so large a mass; secondly, how the femoral vein, lying immediately to its outer side, escapes pressure, even though it is protected by a septal wall of fascia, and in this case there was no evidence of venous congestion in the limb below; and thirdly, the important question as to how so large a sac should be dealt with in a hernia of such long standing had operation been unavoidable.

#### URINARY CALCULI, WHICH HAD ESCAPED SPONTANEOUSLY THROUGH THE URETHRA—SUGGESTIONS AS TO CLOVER'S APPARATUS FOR THEIR REMOVAL.

DR. FLEMING exhibited a large collection of urinary calculi, the majority of which had escaped *spontaneously* through the urethra. He alluded to the diagnostic peculiarities of each class of calculi—as renal, vesical, or urethral. He also exhibited his modification of Clover's apparatus for the removal of lithotritic detritus, and recommended its application, with the substitution of a suitably formed gum-elastic catheter, in cases as the above. He considered it a much safer mode of proceeding, in many instances, especially *when the urethra was previously largely dilated*, than that usually adopted of "crushing" with the lithotrite.

#### CASES OF ANOMALIES IN ANATOMICAL STRUCTURE.

By ALEX. MACALISTER.

It seems to be a natural law, that there is a tendency during the process of development, towards the perpetuation of embryonic forms, and this we find to be a fruitful source of anomalies in structure. To this law may be appended a corollary, that those organs which in their adult condition present the greatest deviations from their typical or fetal state, will be the most liable to exhibit reversions to original conformation, and consequently will be the most irregular. The arch of the aorta and its branches exhibit anomalies, perhaps more frequently than any other portion of the vascular system, indeed, perhaps more frequently than any other portion of the body; and when these are considered in the light of the embryological and zootomical relations of this vessel, much interest is added to the task of collecting such varieties. In the examination of the body of a female subject in the dissecting-room of the Royal College of Surgeons, I met with the interesting specimen which I have at present to describe. The individual was a spare, rather feebly-developed, middle-aged woman, about five feet three in height, narrow-chested, and with a prognathous conformation of skull. On opening the cavity of the thorax and dissecting the front of the neck, the following appearances were observed:—

The heart was a little hypertrophied, and its left ventricle gave off the aorta in its normal position; this vessel after sending off the two coronaries and arter ascending to the right as usual, turned upwards, backwards, and to the left side, giving off in the situation in which the left common carotid usually arises, a large common trunk, seven lines long, a little to the left of the position in which the sinus of Morgagni is generally found. This common trunk,

which in calibre resembled the arteria innominata, after passing upwards, backwards, and to the left, divided into the two carotids. The right vessel crossed the neck rising obliquely backwards and to the right, slightly sinuous in its course and lying on the sixth and seventh rings of the trachea, concave backwards and to the right side below, assuming its normal position opposite the second ring of the trachea or the lower border of the right lateral lobe of the thyroid body. The left carotid passed upwards from its origin nearly in its usual position, as the point of bifurcation of the common carotid trunk was directly on the level of the left border of the trachea, and below the level of the sterno-clavicular articulation opposite the lower border of the cartilage of the first rib. The left subclavian trunk was normal in position and in the arrangement of its branches, but the right arose from the transverse portion of the aortic arch just where it turned downwards posterior, and to the left side of the left subclavian, and behind and above the point of insertion of the ductus arteriosus, it passed upwards and to the right side posterior to the œsophagus and trachea, was crossed at its origin by the left recurrent laryngeal nerve. The right pneumogastric nerve passed over it as it emerged from behind the œsophagus and the right recurrent laryngeal did not hook round it in the usual position, but passed directly inwards to the side of the larynx. The apex of the right lung was notched by it, and it crossed behind the trachea corresponding to the eleventh, twelfth and thirteenth rings.

Among the similar instances of irregularities in the branches of the aortic arch, cases are recorded by Zagorsky\* of a common trunk on the left side giving origin to the two carotids and the left subclavian, a rare condition which I have seen myself once.† Instances are recorded likewise by Haller and Meckel‡ of the two carotids arising by a common trunk, an arrangement which I have likewise seen and which is found to be typical in the elephant. In this animal, however, the subclavian arise on either side of the common trunk. Walter,§ is as far as I am aware, the only anatomist who has ever noticed an irregularity similar in most respects to that in the present instance, and his description is to be found in the *Memoirs of the Berlin Academy for 1785*. Mr. Green,§ in speaking of the tendency of arterial deviations to the left, describes a specimen in which the right carotid gave off the right vertebral and crossed the trachea: "The left carotid and subclavian arose nearly from the same point, the right subclavian was detached from the back part of the arch a little below the left subclavian, and passed to the right side behind the œsophagus and trachea."

The fact of the origin of the right subclavian to the left of the other branches has been noticed by several anatomists, and Professor Harrison|| says, regarding it, that in such cases there is no innominata, and the right carotid arises from the arch in its place; this, however, is not confirmed by our present specimen. The surgical importance of this variety is considerable, as its relation to the œsophagus might lead to serious complication, either from accident or disease, as in the celebrated case of Mr. Kirby's, in which a fish-bone pierced the subclavian as it passed behind the œsophagus.¶ The right carotid in crossing the trachea might give rise to dangerous complications in the operation of tracheotomy, especially in children.

Although the embryological relations of this variety have been very ably discussed by several observers, yet that portion of the subject has scarcely been exhausted. Mr. Hart has described a corresponding case in the *Edinburgh Medical and Surgical Journal* for April 1826, and he has called attention to the important fact of the relative position of the inferior laryngeal nerve to the anomalous right subclavian, as showing the true reason why in man we find the right pneumogastric giving off its recurrent branch

round that artery, and, in fact, why the inferior laryngeal should be recurrent at all, for as the embryonic cerebral vesicles are developed from the outer layer of the blastoderm, on a plane anterior to the middle or vascular lamina in which the primordial bronchial arches are formed and the rudimentary laryngeal apparatus is originated posterior to these embryonic arteries, then, as the vertical development proceeds, the laryngeal nerve cords going from before backward will be hooked round the fourth arch, or that which becomes the arch of the aorta on the left and the third, or that which is developed as the subclavian on the right, both of which are the second lowest of the persistent arches, and thus when the right subclavian passes behind the trachea, the nerve and viscus being on the same side of the artery, of course the former will pass directly to its destination.

The nature of the present instance seems to depend upon the arrest of the usual obliterative development in the formation of these vessels, so that the common carotid trunk is derived from the prolonged central stem giving off the first pair of bronchial arches. The second pair is, as usual, obliterated; the third pair is developed as the subclavians, whose fetal community of origin explains the proximity of their trunks, although it is hard to account for their crossing, or the passage of the right trunk behind the trachea. The fourth arches then form on the left the arch of the aorta, while on the right it is represented by the ductus arteriosus and right pulmonary trunk. We have then the left pulmonary as the representative of the left fifth arch, while the right fifth is absent.

It may, perhaps, be worthy of note that in the same subject the molar teeth were very much flattened and ground, an appearance very common in the teeth of the ancient skulls found in the peat and recent deposits in Ireland. In the lower jaw she had but two molars on one side and one on the other, and there was no appearance of diastema or gago, so apparently this was the entire number which she possessed below the upper teeth—sixteen in number; and the crowns of those molars which had no opponents in the lower jaw, were much less worn than those which were in contact with inferior teeth.

In another subject in the room, a little before the already described specimen, the superior profunda, inferior profunda, circumflex, and subscapular arteries arose by a common trunk from the back of the first stage of the axillary artery, the abnormal vessel taking the normal position of that artery, while the real trunk lay anterior to all the other parts in the axilla. This anomaly is not of very rare occurrence. I have on several occasions met with it before.

I have also seen several specimens of abnormal muscles, which might be worth examination. One is a distinct and well-developed example of the infra-spinatus secundus, or subscapulo-capsular, passing from the axillary costa of the scapula to the lesser tuberosity of the humerus external to the capsular ligament anterior to the long head of the triceps, of which I have given a fuller description in the proceedings of the Royal Irish Academy for July, 1866. It has been also met with by Gruber and Henle.

I have likewise to exhibit in the same subject a double coraco-brachialis, the second or shorter piece being quite separate from the first or larger portion; the former arises from beneath the coracoid process, and is inserted into the humerus in common with the insertion of the latissimus dorsi. It will be seen to be quite separate from the capsula of the shoulder. Mr. Wood, who has met with this slip four times, describes it as being connected to the capsular ligament. Cruveilhier and others have also described it. The first-named author has given an admirable account of its relations in the *Journal of Anatomy and Physiology*, vol. i., No. 1., p. 47.

Another and interesting variety is a fusion of the flexor of the fingers and thumb, in which the indicial portion of the flexor profundus digitorum is completely and closely connected to the flexor pollicis by cross-connecting slips. Gautzer has mentioned this as a rare occurrence, and it is not an uncommon arrangement among the quadrumana.

I might mention one other remarkable case which I

found in the dissecting-room a few days ago—namely, the crossing of the common carotid artery by pneumogastric nerve in the middle of the neck; the nerve ran from without inwards, across a curve in the vessel, again crossing it below to resume its original position.

## Reviews.

### EDINBURGH MEDICAL JOURNAL. January, 1867.

THE present number contains four original communications, five reviews, and other miscellaneous matter. The opening article, by Dr. Scoresby-Jackson, is a well-written and most interesting paper on "Amnesic Aphasia;" and details particulars of a case of typhus fever which was followed by right hemiplegia and loss of intellectual language, both articulate and written. This paper is illustrated by eight plates, and gives more than ordinary interest to the number in which it appears. The other original papers by Drs. Veale, Heron Watson, and Matthews Duncan respectively, are also worth reading, those of Dr. Heron Watson and Dr. Matthews Duncan being illustrated by wood engravings.

### THE JOURNAL OF ANATOMY AND PHYSIOLOGY.

Conducted by G. M. HUMPHRY, M.D., F.R.S., of Cambridge; ALFRED NEWTON, M.A., F.L.S., of Cambridge; WM. TURNER, M.B., F.R.S.E., of Edinburgh; E. P. WRIGHT, M.D., F.L.S., of Dublin; and (as Editor) J. W. CLARKE, M.A., Fellow of Trinity College, Cambridge, and Superintendent of the University Museums of Zoology and Comparative Anatomy. No. I. Macmillan and Co., London and Cambridge.

THIS journal, originating, we believe, in the University of Cambridge, is intended to supply the want which has long been felt of a medium of communication between scientific men on subjects connected with the progress of anatomy and physiology, the discussion of which subject occupies but a subordinate position in the medical journals, and is not generally admitted in the ordinary scientific periodicals. The present number, which is remarkable for the interest and variety, as well as the intrinsic value of its contents, contains a series of papers by some of the most distinguished anatomists and physiologists of the present day, together with reviews and reports on anatomy and physiology. The opening paper is the Address in Physiology, delivered by Dr. Humphry, at the meeting of the British Association at Nottingham last year, and this is followed by papers by Professor Huxley, Mr. Turner, of Edinburgh; Mr. Wood's, of King's College, London; Mr. Hulke, of the Middlesex Hospital, and others. Of the two reviews, one is a most learned and elaborate one on Owen's first and second volumes of the "Anatomy of Vertebrates," and the other, a short one of the first part of Dr. Beale's edition of Todd and Bowman's "Physiology." Dr. W. D. Moore, whose accomplishments as a physician and a linguist are well-known to the medical profession, figures largely in this number by his notices of some recent Dutch and Scandinavian contributions to anatomical and physiological science, and he also translates two papers by Dr. Donders, the well-known Professor of Physiology and Ophthalmology at Utrecht. The report on anatomy is by Mr. Turner, and that on physiology, by Dr. Rutherford, of Edinburgh, and they embrace the most recent researches on those subjects in this country and on the Continent.

THE NERVOUS SYSTEM. By LUDOVIC HIRSCHFELD, Professor of Anatomy to the Faculty of Medicine of Warsaw. Edited in English by ALEXANDER MASON MACDOUGAL, F.R.C.S., with Artistically Coloured Lithographic Illustrations, designed by J. B. Léveillé. London: Churchill and Sons. 1866.

THIS is the first instalment of a work which is to be completed in twelve parts, and is intended to illustrate the anatomy of the nervous system in man. It has already attained great celebrity on the Continent, and has been adopted by the Supreme Council of Public Instruction in France. The text is translated from the French edition of 1866, the anatomical nomenclature usual in Great Britain being adopted, and as far as the present part enables us to judge, the translator has performed his task with great clearness and accuracy. The illustrations which constitute the chief feature of the work, will embrace the anatomy of the entire cerebro-spinal and

sympathetic nervous centres and distributions, with their relations, and they consist of coloured lithographic delineations copied from dissections made by the author after an eight years' service as demonstrator at the *Ecole Pratique* of Paris, and a further experience in neurology, obtained by him in preparing the specimens employed in producing the voluminous and expensive work of Bourguery. The present number contains five plates, three being single, and two double, and representing the vertebral- and cranial dura mater and arachnoid membrane, and we have certainly never seen more beautiful or accurate representations of the structures they are designed to display, while the accompanying letterpress, placed opposite to the plates, gives a description of every anatomical point deserving the attention of the student or practitioner.

THE INDIGESTIONS OR DISEASES OF THE DIGESTIVE ORGANS FUNCTIONALLY TREATED. By THOS. KING CHAMBERS, M.D. London: J. Churchill and Sons.

THIS elegant volume, by the author of "Lectures, chiefly Clinical," has been our Christmas book, for though dated 1867 an early copy came into our possession, and we found it as interesting as any of the popular annuals which deluge us at that festive season. Moreover, it is got up in a manner which, for a medical work, can scarcely be surpassed. We hope the author will accept as a well-deserved compliment the remark that after all that has been written upon the subject, we consider it a thorough triumph to have put forth so instructive a volume on indigestion. We have never, to our knowledge, seen Dr. Chambers, but we have often envied those who have had the privilege of his clinical teaching. This statement is our preface to the information we offer the reader—that the book to which we are drawing attention is eminently clinical. It is not, indeed, a series of lectures, but it contains no less than 227 cases briefly, but graphically, described, and these form the skeleton which, the author says, he has "articulated together by argument, and tried to make muscularly active by practical observations." He has succeeded in the trial; nay, more, this "muscular activity," he has clothed with all the beauty of a clear and fascinating style. This being our opinion, we shall not be expected to mutilate his creation by quotations.

We cannot, however, persuade ourselves to lay down our pen without indicating some of the subjects included in this volume.

The Second Chapter is devoted to indigestion of the various foods—starch, albumen and fibrin, fat, water. The treatment of these is based on the pathological condition.

In the next Chapter we have an account of habits of social life leading to indigestion, the treatment being discontinuance. Many most valuable hints will be found in this division.

Abdominal pains, vomiting, flatulence, diarrhoea, constipation, and nervous diseases connected with indigestion, form the subjects of succeeding chapters.

We should have been glad to enter more fully into the work, and subject some of the propositions to more rigid scrutiny, but we are sure it will soon be widely known to the profession, and it treats of a subject on which every one of our brethren can compare notes with the author.

GOUT AND RHEUMATISM IN RELATION TO DISEASE OF THE HEART. By A. W. BARCLAY, M.D., Physician to St. George's Hospital, &c. Pp. 214. London: Churchill and Sons. 1866.

ALTHOUGH our medical literature abounds in books relating to the pathology, the diagnosis and the treatment of heart disease, as resulting from or associated with gout and rheumatism, yet Dr. Barclay from his extensive experience, especially in the practice of St. George's Hospital, is fully entitled to a hearing when he expresses his views on these very important topics. Indeed the very abundance of the treatises to which we have adverted renders the attainment of an accurate judgment as to pathology and treatment a matter of extreme difficulty to the conscientious reader, for unfortunately the views of different authors disagree so widely, and yet are all apparently founded on such strong arguments and such extensive experience, that the practitioner is puzzled which authority to choose as the most trustworthy guide. It is no disparagement to the merits of Dr. Barclay's present treatise to state that he has not satisfactorily cleared up many points of difficulty still existing as to the nature of the two diseases which it is intended to illustrate, nor has he struck out any remarkable novelties in reference to their treatment, or that of

the cardiac affections of which they are the forerunners or the complications, but he deserves the credit of having put together some ingenious hypothetical views as to pathology, some useful practical hints as to diagnosis, and some careful and well-considered directions as to treatment.

His hypothesis, for it cannot be called a theory, as to the nature of gout, is that the disease consists in some organic change in the constitution of the blood corpuscles, and to the objection that these corpuscles are perpetually destroyed and renewed, while the very essence of gout is to be found in its life-long continuance and its hereditary tendency, he answers by referring to the scars of wounds which retain their character although their material is always changing, and to the features of an individual human being, which, although liable to some alteration, maintain always a general resemblance, notwithstanding the periodical decay and renovation of the tissues. As to rheumatism, Dr. Barclay has little to remark as to its nature, except that it is somehow connected with an excess of acid in the system. That gout is not caused by the excess of lithic acid in the blood, but that the undue presence of this acid is an accompaniment only of the disease, is, he thinks, proved by the failure of the alkaline treatment to relieve a paroxysm of gout, while relief is at once afforded by specifics; but, on the other hand, whatever may be the essential nature of rheumatism, Dr. Barclay strongly approves of the alkaline treatment, which, as he believes, is proved by statistics to have very materially diminished the tendency to heart disease, and consequently to have lessened the mortality.

We regret that our limited space forbids us from entering more fully into the consideration of Dr. Barclay's book, which is well worthy of perusal as a thoughtful treatise on two very common and yet obscure complaints.

**THE USE OF THE LARYNGOSCOPE IN DISEASES OF THE THROAT:** with an Appendix on Rhinoscopy. By MORELL MACKENZIE, M.D., &c. Second Edition. Revised and Enlarged. London. 1866. Pp. 156.

WHEN a work like the one before us, written for a limited class of readers, reaches a second edition in some twenty months, it requires little commendation from the reviewer, the verdict of the profession is its highest praise. We should not, however, be doing our duty either to the author or to our own readers if we did not refer to the additions and improvements made in this second edition of Dr. Mackenzie's book. In the first Chapter, which consists of an admirable and instructive history of the various attempts made to inspect the interior of the larynx before the time of Czermak, we find another name now added to the list of pioneers in laryngoscopy—that of M. Cagniard de Latour, who, "in the year 1825, made an unsuccessful endeavour to examine the larynx during life."—(Pp. 9-10.) This addition makes the history of the invention complete—we allude to it chiefly to show the care and industry with which our author has investigated the literature of his subject. The explanation of the principles of the formation of the laryngeal image (Sec. I., Chap. 3), has been much improved, not only by a clear exposition in the text, but also by some useful illustrations. This section will be much valued by all beginners in the art of laryngoscopy, and will enable them to readily understand a part of the subject, which is difficult, but on which it is essential to have clear ideas.

Several very ingenious inventions, which the experience of the author has led him to devise, are figured, in addition to those described in the first issue. Among others, we may especially refer to the rigid wire loops (page 120), which will be found invaluable in the treatment of many cases of laryngeal growths in which the forceps is inadmissible. Valuable directions are given for the preparation of solutions for local application, and of others for inhalation. This we consider an important addition, and it will, doubtless, add to the popularity of the book. Mayer's atomizer is recommended instead of Lewin's, mentioned in the first edition—a more extended experience has, doubtless, led to the preference expressed.

In the cases given by an author writing on such a subject as the use of the laryngoscope we have the best data for founding our opinions of the value of the instrument, and in the recorded experience of the writer we find the best materials for guiding us in the treatment of similar affections. Dr. Mackenzie gives us a number of fresh cases that will be acceptable to all who take an interest in the progress of medicine. Several of them illustrate the value of the laryngoscope in the removal of growths and foreign bodies from the interior of the larynx, others teach us the value of the direct application of galvanism

to the vocal cords, while a third set illustrates the value of rhinoscopy. For applying galvanism to the larynx Dr. Mackenzie has invented a very ingenious little instrument, which we can say, from our own experience, is invaluable in treating many cases of functional aphonia.

The book possesses two more great merits: it is clearly and in places elegantly written, and it is brought out in a style which reflects great credit on the publisher. The type is good, and by a little closer printing than in the first edition has enabled the author to add a considerable amount of new matter without increasing the bulk of the volume. Marginal references are found on every page—an addition which we heartily wish other medical authors would adopt.

Medical and scientific works are too often printed in the smallest type on the worst paper, and bound in the saddest looking colours. A change promises to set in to replace this puritanism of the past, and we recommend the book we have just spoken of as a good example for authors to imitate.

**TRAINING IN THEORY AND PRACTICE.** By ARCHIBALD MACLAREN. London: Macmillan and Co.

IN the volume before us, the author has gone so thoroughly into the subject of exercise in its various forms for the development of the muscular system, that we cannot but pronounce it as one of the most concise and elaborately prepared works we have seen on this all-important matter.

Englishmen are, as a body, fond of exercise, and those manly sports, such as cricket, rowing, &c., are in no other country so popular or more resorted to in leisure hours. But, as Mr. MacLaren remarks, "the use often becomes abused," and in these pages the reader is shown to what extent he may go without injury to his constitution, and the bounds over which if he steps by an immoderate love of work, that constitution may be irreparably sacrificed.

In the opening chapter the author asks—"What does exercise do towards the life, health, and strength of the body? How do lifting and carrying, pushing and pulling, running and jumping, do us good? In fine, what is exercise?" He then endeavours, in a lucid and common sense manner, to solve the problems which have so often been mooted on the training of youth, and concludes his ably written treatise with an appendix of some forty pages, with tabular forms on diet, weight, duration, &c., which to the younger portion of our readers especially, will be found an invaluable guide.

**ACHOLIC DISEASES;** comprising Jaundice, Diarrhoea, Dysentery, and Cholera, with a preliminary Dissertation on Bile, the Biliary Function, and the Action of Chologogues. By ALEXANDER CHAS. MACLEOD, L.K.Q.C.P.L., M.R.C.P.L., &c. Pp. 230. London: Churchill and Sons. 1866.

THIS book exhibits a considerable amount of practical experience and much power of reflection and observation, but we do not think it will do much to extend the domain of scientific medicine. The author labours somewhat unnecessarily to prove the importance of the part played by the bile in the animal economy, and he therefore argues that the cure of many affections is to be obtained by restoring or increasing the biliary secretion. He also takes care to point out the essential differences existing between the hepatic secretion and that of the kidney, although it is scarcely requisite to insist upon this point when writing to medical men who are fully aware of the distinction. In some respects we cannot help thinking that Mr. Macleod is incorrect in his conclusions, as where he assumes that of the bile secreted daily *twenty-nine parts are absorbed*, and one only evacuated. He founds this view on the fact that the quantity of bile voided with the faeces in a condition of health does not exceed one scruple, or about the three-hundredth part of the daily secretion; but he apparently forgets that, although bile does not appear as *bile* in the intestinal evacuations, its constituents pass away in the form of resins or some other hydrocarbonaceous form. As a corollary from his fundamental propositions, Mr. Macleod argues that the best remedies for the diseases he includes in his title-page are to be found in chologogues, and especially mercury.

**CURRENT LITERATURE.**

*Pavilion Asylums*, by C. Lockhart Robertson, M.D., is a pamphlet on the application of the pavilion system of hospital construction in the building of lunatic asylums. This system may be said to be now firmly established. The magnificent

military hospital at Woolwich is built in this manner, and we believe the new St. Thomas's Hospital is to be constructed on the same principle. Dr. Robertson has drawn a plan for a pavilion asylum to accommodate 250 inmates, with capacity for extension to 550, which appears to us complete and commodious.

We have also received Dr. Nelson's excellent Introductory Lecture at Queen's College, Birmingham, entitled, *Collegiate Education in Relation to the Inter-Community of the Sciences.*

#### NEW EDITIONS.

*On Malformations of the Human Heart.* By Thos. B. Peacock, M.D. Second Edition, with Plates. We are glad to announce the new edition of this standard work on its subject, which has been carefully revised and brought down to the present date by the author. The plates are very valuable.

*The Surgical Diseases of Women.* By Baker Brown, F.R.C.S. Third Edition, with Illustrations, by I. Baker Brown, jun. The chief addition to this edition consists in the plates, drawn with a degree of fidelity seldom witnessed, by the son of the author. These are alone worth the price of the volume, the value of which is well-known to the profession. This edition contains the author's latest experience on those plastic operations for vesico and recto-vaginal fistulae, for which he has so long been distinguished.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 23, 1867.

### THE BETHNAL-GREEN GUARDIANS AND THEIR MEDICAL OFFICERS.

In the year 1864 the Poor-law Board at Whitehall sanctioned and encouraged the Bethnal-green Guardians in dismissing one of their Medical Officers upon charges which were perfectly frivolous and untenable. The farce of an inquiry was indeed gone through on the part of the Government, and the result was, that the Medical Officer in question completely disproved all the accusations made against him by the Guardians, except, we believe, that he had occasionally used in his entries black ink instead of red, or red instead of black, or had committed some such trifling delinquency. The real fact was that the Medical Officer had done his duty too faithfully to the sick poor, and had thereby incurred the hostility of the Guardians, for he had, unfortunately for himself, exposed a great number of instances wherein the death of patients had been caused by culpable negligence on the part of the authorities, or by the omission of due sanitary precautions. This conduct on his part was, of course, unpardonable by the Bumbles of Bethnal-green, and the Poor-law Board, although they did not pretend that any serious charges had been established against him, called upon him to resign on grounds of expediency, as they did not think that he and the Guardians *could act together in harmony!* The period to which we refer was one in which the movement for Poor-law Medical Reform

had not yet made much impression upon the public mind, and any Poor-law Medical Officer who urged a more humane treatment of the poor than was practised by his superiors rendered himself liable to dismissal. Even our medical contemporaries gave a very feeble support to any Medical Officer placed in such a dilemma, however honourable or blameless his conduct might have been, while the general press ignored the matter altogether. It was only at a subsequent time that the chief organs of public opinion appeared to awake from their indifference, and to discover that sick paupers were, after all, human beings, and that those who advocated their kind treatment were worthy of praise and reward rather than of censure and dismissal.

These same Guardians and one of their present Medical Officers are now involved in a very unpleasant inquiry in reference to the death of a patient under circumstances of a very painful nature, and in which the Medical Officer, Mr. MASSINGHAM, is inculpated. A Coroner's Inquest has been held, and a verdict has been returned reflecting strongly upon the negligence said to have been displayed, and the consequences have been that Mr. MASSINGHAM has been suspended from his situation, and a Poor-law inquiry has been instituted by one of the Poor-law Inspectors. As matters stand at present in reference to Poor-law Guardians and their Medical Officers, the latter may regard his dismissal with indifference; but as in the present instance very serious accusations have been made upon Mr. MASSINGHAM's conduct, and as these accusations have been repeated, with the usual exaggerations, by some of the cheap papers, it is not an inappropriate time to point out some of the leading features of the case. If Mr. MASSINGHAM should be dismissed on the report of the Poor-law Inspector, the fact will be no disgrace to him, inasmuch as the Poor-law Board sanctioned the dismissal of one of his former colleagues for showing too great zeal in behalf of the sick poor. But there is a sentiment of justice and humanity in the public mind independent of the shortcomings of Poor-law Guardians or the redtapeism of the Poor-law Board, and the case of Mr. MASSINGHAM must be dealt with according to its own merits.

It appears that a poor woman was taken in labour in Mr. MASSINGHAM's district on the 2nd inst., but she was not his patient, nor was he in any way bound to attend her during her confinement. She was in fact on the point of being conveyed to the Lying-in Hospital of the City of London, for which institution she had a letter, but in consequence of the state of the streets from the heavy fall of snow, the cabman who was called refused to take the poor woman, except at an advance of his fare, and the money not being forthcoming, she was confined on the floor of the room where she was waiting

until the question of the fare could be adjusted. Now, here in the first instance, the circumstances leading to the abnormal delivery were the inclemency of the weather, the state of the streets, and the refusal of the cabman to take the fare at the usual rate. Subsequently, however, in the evening an order was procured from the overseer for the attendance of the district surgeon, but as it was not marked as a midwifery order, and was not accompanied by any special directions, nor presented by the bearer as a document requiring immediate attention, its consideration was postponed in the usual course till the next morning. But before his ordinary hour for going to see the out-door patients, and while his surgery was full of applicants for medical relief, Mr. MASSINGHAM was again requested to see the woman. That he did not immediately respond to this summons, is a circumstance to be regretted, and the only excuse that can be offered is, that among the lower classes of patients it is so common to demand the attendance of parish surgeons in terms of exaggerated urgency, that frequently the application fails to receive immediate attention. But be this as it may, Mr. MASSINGHAM was on his way to see the woman in about an hour, when he was himself taken ill and obliged to return home, and he sent his son (a gentleman, we understand, in his twenty-first year) in his place. The poor patient, however, died soon after this visit, and before Mr. MASSINGHAM'S arrival, which took place an hour afterwards. The cause of death seems to have been effusion into the pericardium, and the case altogether was an exceptional one, but we confess that it does not appear that Mr. MASSINGHAM'S conduct was so culpable as has been represented, although the result was unfortunate; and it was also unfortunate that he should himself have been labouring under illness when he went to attend the patient. The fact of sending his son, who was unqualified, and therefore technically incapacitated from acting as his substitute, was, perhaps, the best course he could take under the circumstances. If the patient's death was in any way connected with her confinement, it is certainly more charitable to believe that the fatal pericarditis was due to the delay in her removal to the lying-in hospital, rather than to any fault on the part of Mr. MASSINGHAM.

### Notes on Current Topics.

**THE CATASTROPHE IN REGENT'S PARK.**—Seldom has such a thrill of horror passed through London society as on the occasion of the break up of the ice which precipitated nearly 200 people into the water in the midst of their pleasure. Nevertheless, it ought not to be forgotten that ordinary prudence would have averted this tragedy. The sufferers have immolated themselves for the sake of a few

last minutes of their pastime. Among the victims were two medical students, one a third years' man at University College, the other a pupil of Dr. Hardwicke's. As in every sad occurrence of life our profession was to the front with its assistance. Dr. Randall and Mr. Fuller, at the Marylebone Workhouse, have already received the public approbation which was their due for the exertions they put forth, and the same may be said of the other workhouse officials. We wish to draw attention to the invaluable services of Mr. Obre at the scene of the accident. This gentleman ably fulfills the duties of surgeon to the Humane Society for this district, and his arrangements were unexceptionable. We may also take the opportunity of thanking Mr. Copland, a student at the London Hospital, for the courage with which he rescued three little girls from drowning, although greatly encumbered by his over-coat and skates. Altogether the profession has been found as ready as ever, when called upon by the voice of humanity.

**YELLOW FEVER IN JAMAICA.**—We regret to announce an outbreak of this disease in the war vessels at Port Royal. Commander Jenkins, of H. M. gunboat *Nettle*, as well as Dr. D'Arcy the surgeon to the troops at Morant Bay, are amongst the early victims. Steps have been taken to isolate the cases in the hope of preventing the spread of the disease. We are glad to report that circulars have been issued by government authority in all the parishes of Jamaica, in reference to sanitary matters, and a special handbill drawn up by Dr. Steventon of the Public Hospital, and containing precautions against the spread of cholera, has been posted in conspicuous places throughout the island. This is well. To be beforehand is the only chance with such an enemy.

**THE ARMY MEDICAL WARRANT.**—It appears the Army Medical Warrant, of which so much has been said, is ready and in type. It will not be published separately, but will be included in the second volume of the "Amended Army Regulations," which will shortly be published. In some respects the new warrant will grant higher rates of pay than those suggested by the committee on whose recommendation it is founded. The protest on behalf of the officers of higher rank has also been attended to. They will receive an increase (of no considerable amount, however) beyond the scale published in a former blue-book.

**INFANTICIDE.**—The subject of child murder is again being mooted in both the London and provincial press, and we sincerely hope Parliament will not have passed its next session without the introduction of and the becoming law of some stringent measures, which shall punish more severely those who commit these diabolical crimes, not passing over those who are primarily the cause, and often the prompters of these last acts to destroy the traces of their shame, and the disposal of the bodies in the hopes of escaping the meshes of the law. A correspondent remarks:—

"There have been some surprising instances of acquittal in cases of infanticide of late, where no apparent grounds have existed for a recommendation to mercy. If the law were allowed to take its course whenever a verdict of wilful murder has been justly arrived at in these cases, we should not be so often shocked by their occurrence, and a more healthy moral tone on this subject would prevail.

"Medical witnesses and juries must do their duty, and not allow any false maudlin views to stand between them and the administration of justice."

**VALUE OF DUBLIN MEDICAL DEGREES.**—It is a curious fact that coincidentally with the steady decline in numbers of the Oxford and Cambridge Medical Graduates, several of the Graduates in Arts of these two ancient Universities come over to Dublin and take their medical degrees there. This was specially noticed in 1866; when among the Oxford men who graduated in medicine in Dublin was a distinguished Fellow of New College.

**STUDENTS FOR THE NAVY.**—Our readers are aware of the last scheme of the Admiralty to obtain Surgeons for the Navy. The department is at its wit's end, and rather than do justice to its medical men, proposes to enlist students for ten years service, before they have obtained their diplomas. The *dodge* has been repudiated by the students themselves in terms which do them great credit. At a meeting of the Junior Medical Society of London, held at University College, the following resolution has been carried with acclamation:—

“That this meeting views with dissatisfaction the proposal of the Admiralty to ‘subsidize medical students of three years’ standing, until they have become qualified medical practitioners on entering into a bond to serve in the navy for ten years,’ as likely to bring discredit on the whole medical profession, inasmuch as the standard of the naval branch of the service would, so far from becoming raised, be considerably lowered by the class of men such an inducement would be likely to bring into it.”

**DISSECTING ALIVE.**—We last week inserted a quotation from the *Veterinarian*, in which the horrors inflicted on horses under the name of science were described. Seldom have the revelations of vivisection been so heartrending. Sixty-four operations, we are now told on trustworthy authority, are performed by French pupils on one living victim. The leading journals have denounced such practices in indignant terms. Whatever may have been urged at times in palliation of certain experiments on living animals by physiologists, who, by-the-by, almost invariably administer chloroform to their victims. There can be no possible excuse for students dissecting animals alive, which is, in point of fact, what the practices revealed amount to. To invoke the name of science on behalf of these cruelties is a profanation which all truly scientific men will condemn. We have heard enough of the use of despotisms. If the most enlightened of all can permit such things in the nineteenth century, surely the indignant people will insist on the cessation of practices revolting to humanity.

**THE STRAND GUARDIANS AGAIN.**—The game between the local and central authorities for administering our Poor-law has been advanced another move during the past week by the Strand Guardians, who have negatived the proposal to appoint a resident officer to the workhouse. The motion for offering the post to Dr. Rogers, which, as we have already shown, was only an attempt to get rid of that *too* able surgeon, was previously defeated. It is now the turn of the central authority. It has long been declared that the Poor-law Board possesses the power to enforce its proposal, and we sincerely hope such may prove to be the fact. But if so, why so long delay decisive action? Local magistrates are not likely to be convinced. They must be compelled.

**THE CASE OF THE “LA PLATA.”**—This steamer, belonging to the Royal Mail Company, arrived at Southampton on Thursday morning, having left St. Thomas on the 31st

ult. Dr. Wiblin, as Superintendent of Quarantine, at once visited her, and found there had been sixty-one cases of yellow fever on board, of which twenty-three had been fatal, and four remained ill. Among the victims was the surgeon of the ship, Mr. Young, who died on the 9th inst., and in reference to whose case it has been asserted that he was already in bad health when sent to take charge of the *La Plata* at St. Thomas. If so, we must deem it very wrong to have placed one already breaking down in a position in which he would be almost certain to succumb. But surely it is time to press the inquiry why these passenger-ships should put into St. Thomas at all? Have not the authorities read in the newspapers how the French mail-boats were recently ordered to avoid an infected port? Who is responsible for the needless sacrifice of these sixty-one lives in a voyage between the 31st of December and the 17th of January? Putting the survivors in quarantine at Southampton—whatever magic effects it may have—will certainly not call these sixty-one passengers from the depths of the Atlantic. Until something is done to prevent the repetition of such occurrences we should strongly advise all would-be passengers to avoid the mail steamers. A longer voyage in a sailing-vessel would at least be preferable to a fortnight's sojourn in a plague-stricken steamer.

**HEALTH COMMITTEES FOR THE POPLAR DISTRICT.**—We have before us the reports of the committees appointed by the Privy Council during the last cholera epidemic to the Board of Works for the Poplar District. There is little doubt that but for the regulations made by the committees for medical superintendence the disease would have been much more extended and fatal. It appears from two very clear and succinct tables by Drs. Woodforde and Ellison, the Medical Officers of Health for the North and South Districts, that the number of deaths from cholera was greatest on the 25th of July, but that the maximum number from diarrhoea occurred about the 5th of August. The number of cases of cholera and diarrhoea attended by the Medical Visitors, with the number of deaths, is well shown in the following table, which we take from the Report:—

Sub-District.	Cholera.	Diarrhoea.	Deaths.
No. 1.	34	1364	29
No. 2.	65	1433	44
No. 3.	50	1962	21
No. 4.	74	222	7
No. 6.	109	1493	36
No. 5.	22	1026	22

It appears in the accounts that the sum of £195, 7s. 4d. had been employed in flushing, deodorising, and disinfecting, and there is little doubt that this amount has been advantageously expended; but we feel bound to remark that the sum of 60 guineas, suggested by the Committee to be given to the Medical Officer (Mr. Ellison), seems small, and the same observation will apply to the sum proposed to be given to Mr. Shadrake, the Inspector of Nuisances. There are, however, two suggestions of the Committees which we should wish to see completely carried out:—1st. “That a Sanitary Committee be appointed.” 2nd. “That it would be a satisfactory alteration of the law if no house were allowed to be tenanted unless a certificate that the premises were fit for habitation were first obtained from the District Board of Works.” On retiring, the Committees especially notice the indefatigable attention, anxiety, and care evinced throughout by the Medical Officers, whose untiring attention most materially contributed to the efficient arrange-

ments so speedily organized. The deepest regret is also expressed by the Committees that they, in common with the Board, have to lament the loss of two such valuable officers as Mr. C. C. Ceely, late clerk, and Dr. Ansell, late Medical Officer for the North District. It will be remembered by our readers that Dr. Ansell was one of the oldest and most esteemed members of the Examining Board at the Apothecaries' Hall. He fell a victim to the disease which he was striving to prevent and cure in others.\* The reports are very clear on some points of importance, with regard to drainage and water supply, and many of the observations would be of great use in making regulations during another epidemic.

#### OUR MERCANTILE NAVY.

On Wednesday Captain Henry Toynbee read before the members of the Society of Arts a paper on "Mercantile Marine Legislation, as Affecting the Number and Efficiency of British Seamen." He said—"Having spent the last thirty-three years of my life among seamen, I have been struck with the importance of some of their wants, and have been trying for some years to get those interested in their welfare to take up the question of their social position, and deal with it in a broad and comprehensive manner. The scarcity of British seamen, and the tendency to discontent which is showing itself in the east end of London, and in several of our seaports, make it more important that those who understand them thoroughly should come forward and explain what really is wanted."

The following is a summary of the changes proposed by Captain Toynbee:—

1. That Government shall establish a pension fund and life insurance adapted to the circumstances of seamen and their families in connection with shipping offices, and join on to them a benefit fund, the principle of which shall be the sums which Government has received and is still receiving as unclaimed effects of deceased seamen; also that the Act be so modified that the wages and effects of deserters shall go to this fund, and that they will consider in what way they can discourage giving a month's advance before starting, except as a payment into the pension fund or life insurance.

2. That Government shall put a stop to scurvy in the mercantile marine by calling for and entering in the heading of the "articles" a new scale of provisions.

3. That they shall increase the space given to seamen to 15 superficial feet of deck, and not less than 90 cubic feet of air; also that they shall require it to be properly lighted, drained, ventilated, and protected from the sea as well as from the gas which rises from cargo. Safe glazed lamps and oil to be provided for their use; and these rights of seamen to be entered in the heading of the "articles of agreement," and a copy hung in the fore-castle.

4. That dock clerks be attached to shipping offices, whose duty it shall be to visit ships on their arrival, see that the crews get part of their pay, and, if they wish, send them to their homes, promising to send the rest of their pay and papers after them.

5. That shipping-masters shall be empowered to order the inspection of all ships' fore-castles and provisions, or at least those of any against which there is a reasonable complaint. Again, that shipping-masters abroad be empowered to make a commander ship another man immediately in the place of one discharged; also that vessels engaging crews to be discharged abroad shall be bound to provide them with another ship or pay their passage home.

6. That Government be moved to provide for the admission of English boys into the mercantile marine, as a means of national defence in case of war, as well as an honest employment of subjects, instead of allowing them to be supplanted by foreigners.

Lastly. That Government be asked to grant public lands in our seaports for married sailors' homes, sailors clubs and institutes, and to encourage in every way the social improvement of seamen, who suffer great temptations from the peculiar circumstances of their profession.

#### CHARGE AGAINST A MEDICAL MAN.

On Friday, at a meeting of the Board of Guardians of Bethnal-green, Mr. Collins in the chair, the conduct of Dr. J. Massingham, the parish surgeon, who was alleged to have neglected a patient named Anne Ferry, under circumstances which a coroner's jury pronounced to be "inhuman, and such as disqualified him from continuing to hold his appointment," came under discussion.

The sister of the deceased and the other witnesses examined at the inquest were called, and repeated their evidence.

Dr. Massingham handed in the following statement:—"On Wednesday, Jan. 2, about seven P.M., a woman brought me an order. I asked what was the matter. She said 'confinement.' I inquired how long the person had been ill, and if she wanted me directly. She replied, 'No, she was confined about eleven o'clock this morning,' and that a neighbour had attended her. I said, 'What did you get an order for?' and she said, 'Because I want some medicine for the after pains,' at the same time giving me a bottle which she had brought for it. I gave her some medicine, and as she was going out she asked me to give her a call on my round next morning. At about half-past ten next morning a girl came to my shop and said her mother was very bad, and she thought dying. I thought the girl came from another patient, who had several times sent to me that she was dying, and I said, 'Nonsense; your mother will not die yet, and I am coming out, and will call and see her.' Directly after, another came, and asked me to go and see Mrs. Ferry, as they thought she was dying. I said she could not be from her labour, but that there must be something else the matter with her. She then told me she was turning blue. I then said, 'She must have some disease of the lungs, and I am coming out directly, and will call on her first.' I went out in about ten minutes afterwards, and had to see a patient on my way to Ferry's house, and while there I had a return of dysentery, which I had been suffering from for three or four days, and was obliged to return home. I immediately sent my son to see her, and he returned and told me she was suffering from congestion of the lungs, and would survive about an hour or so. He prescribed remedies for her. As soon as I was able to get out again I went to see her, and found her dead."

The Rev. Mr. Hansard said that the statement of Dr. Massingham did not contradict the evidence before the board; but simply alleged that a totally different colour was given to the messages by the way they were delivered to him—that, in fact, he had no reason to believe that the case was so serious as it really was.

After a long discussion generally condemnatory of Dr. Massingham's views relative to the time he considered a patient might be left unattended, and of his conduct in this especial case, a member of the board said that the course taken by the board should be such as would distinctly mark their disapproval of Dr. Massingham's conduct. He therefore moved that Dr. Massingham be suspended, and that the evidence and Dr. Massingham's statement be forwarded to the Poor-law Board.

This motion was carried unanimously.

## Correspondence.

### CLITORIDECTOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although a dissentient from the views entertained and expressed on the above subject by Mr. Baker Brown, I cannot but acknowledge my admiration of the "pluck" displayed by that gentleman in battling against the opinions of the major portions of the profession, perhaps in many cases prejudiced; for no sane man can deny that we are, as a body, too conservative in our ideas of anything new, and are apt to regard them as innovations to be stamped out as a disease, and the luckless introducers of them denounced as quacks.

\* On the 24th of last July, as related in the obituary of him published the following week.

In the present case, however, Mr. Baker Brown has come forward boldly, and as a man he offers "to place every facility" in the hands of a committee to be appointed by the Obstetrical Society, for "investigating his cases most rigidly."

Nothing can be more straightforward than the letter in your journal of the 16th; and I sincerely hope the Obstetrical Society, in whose province the matter is, will accept the challenge, and impartially sift both theory and practice.

If such operations are necessary, and the results lead generally to a satisfactory issue, then let it go forth to the profession for their benefit and that of their patients, that Mr. Baker Brown is THE man; but if it is proved to be trash and worse than useless, as many imagine, then the strongest language will be inadequate for the denunciation of a theory, which, it must be confessed, is fraught with dangers both socially and morally.—I am, sir, yours, &c.,

A SUBSCRIBER.

#### PALL MALL GAZETTE TESTIMONIAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR—The spirited conduct of the Proprietors of the *Pall Mall Gazette* in protecting the interests of the public and the honour of the profession, in the article upon Dr. Hunter, and in the defence of the case of Hunter v. Sharpe, has already been the subject of favourable comment in your pages.

Several members of the Profession and a few other gentlemen think it desirable to show some mark of their appreciation of this conduct, and propose to join in a limited subscription, the disposal of which shall be hereafter determined.

We beg to request your assistance in making known their intentions, and in furthering the object they have in view.

G. D. POLLOCK, Esq., 27, Grosvenor-street; and T. H. HILLS, Esq., 45, Queen Anne-street, have consented to act as treasurers and subscriptions may also be paid to the Argyll-street branch of the Union Bank.—We are, sir, your obedient servants,

G. W. CALLENDER, 47, Queen Anne-street.

J. W. PARKINSON, Arts' Club, Hanover-square, W.

#### MR. RICHARDSON'S REPLY TO MESSRS. SMYLY AND HOLT.

PERREVE'S STRICTURE DILATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I confess to some disappointment on finding that Mr. Philip Smyly, in his letter in your number of the 9th instant, so "dexterously" evaded answering the question I put to him in my communication of the 12th of December—namely, "In what portion of Mr. Holt's memoir, which has now run through two editions (1861 and 1863), such an acknowledgment or mention of Perrève's name is to be found," as stated by Mr. Smyly in his letter of the 21st of November. Mr. Smyly there having asserted, that the idea of his (Mr. Holt's) instrument, "Mr. Holt himself acknowledges he derived from Perrève's."

It appears to me, that in a matter in which honour is implicated and a question of truth is involved, Mr. Smyly should not have lost a moment in pointing out, if possible, where such an acknowledgement is recorded by Mr. Holt.

I am not aware of any such admission. There is no mention whatever, of Perrève's instruments or mode of treatment in Mr. Holt's lectures on the "Immediate Treatment of Stricture of the Urethra," in the *Medical Times and Gazette* for 1861; and I am equally positive, that there is likewise no allusion to Perrève in either of the two, and only editions, of Mr. Holt's memoir, subsequently published.

Instead of Mr. Smyly explaining that matter and keeping to the point in dispute—viz., the differences between M. Perrève's and the so-called "Holt's" dilators, he leaves the latter duty entirely to Mr. Holt, most ingeniously substituting a totally

distinct question. For, he asks: "Can an instrument brought before the profession in 1847, and rejected as dangerous, be the same as that introduced many years later by Mr. Holt, and received as valuable and safe?"

What the candid reader and Mr. Smyly will have to say is not whether the instruments "can" be identical, because the results are different, but whether they are so or not?

I have never denied that Mr. Holt uses the instrument differently, as he is at some pains to show, and if there is in reality any difference in result, it is due to that, and not because the instruments are different. For they, I again repeat, with the exception of the conducting-rod being hollow, in the so-called Holt's dilator, instead of solid, are identical; Perrève's, which I have now before me, having all the essentials for safety, which Mr. Smyly is here again called upon to prove not to be the case. And, at the same time, would he be good enough to show where the records are to be found of the injuries inflicted by an *undoubted* Perrève's instrument, that, as he asserts, led to its rejection as "dangerous?" If I do not mistake, he will be unable to adduce any cases of the kind from the records of either British or Irish surgery.

I apprehend that the reason Perrève's system lapsed, as many others have done, was, from its inventor not having kept it constantly before the public—an advantage which certainly has not been lost sight of by Mr. Holt!

Whether Perrève died or not soon after 1847 I cannot say; but, had he taken a hint from the modern and worldly-wise system of writing cheap, popular little books or pamphlets, with taking titles addressed to the public; and not contented himself, as he did, with a scientific octavo, which was never thrust before any public, professional or otherwise, I make no kind of doubt that Mr. Smyly's taunt would not have been applicable.

That the profession ever "rejected" Perrève's instrument is a mere assertion. He did not succeed in establishing it, which is quite another thing, and perhaps for the reason I have given. Hence, neither his system nor his instrument was known here, and therefore I shall feel surprised if Mr. Smyly can find any cases of its ill-success from our practice.

The matter at issue between us being—whether the instrument called "Holt's dilator" is the invention of M. Perrève or of Mr. Holt, I am really at a loss as to Mr. Smyly's meaning when he says that he used the term "mis-statement" in his letter alluded to, knowing that I "was well acquainted with the facts of the case, not only from the very able paper of" his "colleague, Professor Macnamara," but also from the discussion at the Surgical Society of Ireland on a paper read by" himself "on the immediate plan" before that Society, "when the differences between Perrève and Holt were discussed."

In consequence of the above observations of Mr. Smyly, I am here compelled to state that, instead of being well "acquainted with the facts of the case," (the structure of Perrève's instruments), from Professor Macnamara's paper, the Professor's description of dilators is not a description of Perrève's instruments at all; for neither of the dilators he attributes to Perrève, are described in any writing of his that I can discover.

It is to be regretted, therefore, that Mr. Smyly did not more closely study his colleague's account of the dilators before he published his letter. If he had done so, I would not now, most probably, be under the necessity of showing, that Professor Macnamara, when he published his paper, had so slight an acquaintance with the structure and arrangement of Perrève's instruments, that his account of them, instead of teaching me "the facts of the case," were on the contrary calculated to lead one completely astray, which I shall now clearly prove.

Professor Macnamara's paper is to be found in the *Dublin Quarterly Journal of Medical Science* for November, 1862. In speaking of the so-called "Holt's dilator," at p. 299, he writes thus:—

"This instrument, the idea of which Mr. Holt acknowledges himself to have derived from M. Perrève" (where?) "resembles one of the two instruments first suggested by this latter gentleman for forcible dilation of stricture of the urethra."

With regard to this observation of the Professor, I shall here mention that in Perrève's work there are not only two, but eight, dilators illustrated, so that on this point the Professor has been mistaken.

Professor Macnamara next observes that "one of his" (Perrève's) "instruments was that which he termed the straight dilator, an instrument composed of two semi-cylindrical tubes united at the vesical extremity by a joint, and terminating at the other extremity, each in a short plate at right angles to the two blades, and traversed by a screw capable of approximating those two handles, as we may term them, to each other."

No such constructed instrument is alluded to by Perrève in his work. The only straight dilator described and illustrated by him being the one here represented (Fig. 1), and which was traced from his original plate and engraved by Mr. Wm. Oldham.

In this instrument the vesical extremities of the blades and conducting rod are represented by Perrève as welded together, and the blades, instead of being divaricated by means of the screw and knee-lever, are separated by the ordinary conical forcere.

I may be wrong in my supposition, but it strikes me, that the Professor's description of the straight dilator applies either to one of the forms of Lyons' dilators, or possibly to a modification of M. Civiale's dilator, illustrated in his "Maladies des Organes Génito-Urinaires." At all events, it is not applicable to Perrève's straight dilator illustrated in fig. 1.

Professor Macnamara further writes:—"His" (Perrève's) "other instrument closely resembled Mr. Holt's present one, with, however, this most important difference, that it contained no central stilette" (conductor), "the safe conduct of the dilators being entrusted to grooves, with which the two blades are channelled throughout their entire extent; the obvious disadvantage of such an arrangement being, that at any moment the dilator might get out of the grooves, and inflict serious injury on the walls of the urethra—a source of danger from which Mr. Holt's modification effectually guards us."

Fig. 2, which is an exact representation of the instrument

in my possession, shows that on this point, likewise, the Professor had fallen into error. Indeed, not one of Perrève's eight dilators is delineated by him as without a conductor!

Such are "the facts of the case" in Professor Macnamara's paper, and from which, according to Mr. Smyly, I must have derived an accurate knowledge of the "differences between Perrève's and Holt's dilators." The real fact, however, being, as just shown, that if I depended on the Professor's description of Perrève's instruments, I could not possibly have had a correct idea of their structure.

Let us now speak of Mr. Smyly's reference to his own communication on the "immediate plan," which was made at the meeting of the Surgical Society of Ireland, on the evening of the 20th February, 1863, and reported in the number of this journal for the 11th March following.

Mr. Smyly in his letter affirms that, "the differences between Perrève and Holt were discussed" on that occasion. It so happens that this is the very reverse of having been the case, as not one of the gentlemen who spoke on the "immediate method" that evening, pointed out the differences between the two instruments. Certainly, neither Mr. Smyly nor Professor Macnamara could have done so correctly, as they were not at the time aware of the actual structure of Perrève's dilators. Professor Macnamara, indeed, named as Perrève's, an old instrument of Mr. Colles', which was produced at the meeting by my late talented friend, Dr. Glascott Symes. But, as Professor Macnamara in the number of the *Dublin Journal*, above alluded to, describes as Perrève's, dilators quite different from any of the instruments illustrated by the latter gentleman, it may safely be assumed, that his having identified Perrève's name with Mr. Colles' instrument, was a misconception on his part.

It is evident, then, that I could not have learned "the facts of the case" from Professor Macnamara's paper, from Mr. Smyly's communication, nor from the discussion thereon; consequently it follows, as a necessary sequence, that even from his own, and only references on the matter, he had no justification, whatever, for applying the offensive term "mis-statement" to my original observation.

Mr. Smyly's reference to his paper has, however, enabled me to refresh my memory, and thereby, possibly, to have justice done in another matter in connection with the so-called "Holt's dilator." For, in that same paper Mr. Smyly appropriates and illustrates as his own, Desault's button-ended metallic (iron) guide, which he (Mr. S.) has added to the "Holt's" dilator, and which he could not have done, but for the conducting rod of Perrève, whose name he now endeavours almost to ignore.

The following quotations from Mr. Smyly's paper, and from Desault's work, placed side by side, will show, that Mr. Holt is not the only surgeon who, without acknowledgement, has been indebted to French ingenuity:—

Mr. Philip Smyly in 1863.

"The guide" ("silver or steel wire") "is about twice the length of the catheter, and is terminated by a small button, which exactly fits the orifice" (at the point) "of the catheter. There is no ring at the opposite end of the guide, so that the catheter may be withdrawn from the bladder without removing the guide."

Desault in 1813.

"Besides, if we fear finding some difficulty in passing the second catheter, it would be easy to obviate this inconvenience by making use of catheters open at both ends; we should introduce the first by means of a stylet with a button, and before changing it we should furnish it with a stylet (guide) about two feet long, which should be pushed some lines into the bladder; then we should withdraw the catheter upon the guide, which must be left in its place, and upon which we may thus conduct a new catheter without trouble, and with safety."—*Œuvres Chirurgicales de Desault*, 1813.

\* Perrève's straight dilator with forcere between the blades.  
+ A. Perrève's curved dilator, with forcere on conducting rod; a little under half real length; cc clamps; d conductor; b separate forcere.—Wm. Oldham, scp.

Although the principle is the same, I need hardly observe, that this is quite a different kind of guide from the cat-gut one Dr. Hutton was in the habit of using, and which is the guide alluded to with such apparent *naïveté* by Mr. Smyly.

Astonished as I am with Mr. Smyly's letter, I am still more so with Mr. Holt's, for the manner in which he has acted towards Perrève, to whom he is under such deep obligation, as I shall show a little further on. But first as to the letter itself :—

Mr. Holt writes that I am "in error. The instrument that I use," says he, "is so different in detail that I am surprised it has escaped Mr. Richardson's observation." "To my mind," he further writes, "it is the difference between failure and success. In Perrève's dilator there are three errors: first, you have no positive means of knowing when the instrument is in the bladder; second, there is nothing to prevent the tube slipping from between the blades; and third, the directing-rod projects so far beyond the handle of the instrument, as to prevent the tube being quickly thrust between the blades, so that the stricture or strictures may be fairly split."

As to Mr. Holt's statement, that in Perrève's instrument "you have no positive means of knowing when the instrument is in the bladder," it should be recollected, that when he (Mr. Holt) first employed his "new" dilator, the two instruments were *actually identical*. It is only of comparatively recent date, that Mr. Holt has made Perrève's directing-rod hollow to attain this object.

In his next statement, "that there is nothing in Perrève's instrument to prevent the tube from slipping between the blades," he is greatly mistaken, as there is the conducting-rod. (Vide fig. 2.)

Again, he says, "Perrève's directing-rod projects so far beyond the handle of the instrument as to prevent the tube being quickly thrust between the blades." Why, this is the very directing-rod which he denies the existence of in his second objection, and which *did* prevent the slipping of the tube! Mr. Holt cuts off a few inches of the conductor, so that he may "quickly thrust" the forcer, which Perrève did not do, and which is the real total of the difference between Perrève's and Mr. Holt's mode of using the instruments, which, with the exception of the *hollow* conductor, I reassert, are identical in form and action.

Before I leave this part of my subject, let me draw the reader's attention to the curious contradictions between Mr. Smyly's two authorities—Mr. Holt, by his admission that there is a conducting-rod, contradicting Professor Macnamara, who denied it in his paper, as I have already shown. While the Professor by stating that there was no conducting-rod for the "safe conduct" of the forcer, thereby implies that it is the conducting-rod which prevents the forcer slipping from between the blades, contradicts Mr. Holt, who asserts that there is nothing to prevent such an accident in Perrève's instrument, which, in his third objection, he admits has a conducting-rod!

I have just pointed out how Mr. Holt has contradicted himself!

To proceed—Suppose, for argument sake, that I admit such trifling distinctions in the mechanism of the instrument have been contrived by Mr. Holt, how is it that he made no allusion whatever to Perrève's instrument originally, and point out in it the "errors" which he has found it convenient now to discover?

Let the reader compare fig. 2, copied from Perrève's plate, with fig. 3, copied carefully from the second edition of Mr. Holt's memoir, brought out in 1863, and ask himself—is it possible to conceive that the latter is not an unacknowledged reproduction of the former?

Fig. 3.\*

Mr. Holt further writes :—"The drawing Mr. Richardson has given" (fig. 3) "does not represent the instrument I now use, and although the principle is the same as Perrève's, the detail is so entirely different as to have insured the use of my modification with almost universal success, while that of Perrève has been entirely abandoned."

The drawing referred to—the largest of the two in fig. 3—which, with the separate forcer, I have had reprinted from my letter of the 12th of last month were traced by Mr. Oldham from p. 4 of the second and last edition of Mr. Holt's memoir. Three illustrations only appear in this edition—viz., the complete instrument, and the separate forcer, and a third, an altered handle, of which I shall speak by-and-by.

The two first were selected by me, because they are the latest delineations by Mr. Holt of the complete instrument, with forcer on conductor between the blades, and separate forcer, beside it, therefore, they were the only drawings published by him, suitable for clearly proving how deeply indebted Mr. Holt was for his "new" dilator to the inventive genius of Perrève.

Mr. Holt's statement evidently proves my position, for his large illustration (of which fig. 3 is a copy), as he himself shows, and which will be seen further on, represents an instrument practically identical with Perrève's dilator, the conductor being solid instead of hollow, a difference between the two instruments I have never denied, and yet no allusion to Perrève was ever made by Mr. Holt until his letter to Mr. Smyly was published on the 9th of this month!

But, for argument sake again, let us admit that Mr. Holt's illustration of the complete instrument, copied by Mr. Oldham as in fig. 3, does not critically represent the instrument he now uses. I ask—Why did he introduce the illustration into the last edition of his memoir? Simply because he well knew that, with the exception of the undisputed *hollow* conductor, it represents all the essentials of the instrument he "now uses," and, therefore, until he finds it expedient, in his letter to Mr. Smyly, to disown Mr. Oldham's *fac-simile* of his illustration he thought it sufficiently accurate for his purpose, as the following description of the illustration will manifest :—

"The instrument by which this simple process (splitting a stricture) is accomplished consists, as is shown in the drawing" (the disowned illustration), "of two grooved blades fixed in a divided handle, and containing between them a wire welded to their points, and on this wire a tube" (refers to the disowned illustration), ("which, when introduced between the blades, corresponds to the natural calibre of the urethra), is quickly passed, and thus ruptures or splits the obstruction." (Please compare with Perrève's description of his dilator in my letter of the 12th of last month.)

\* Copied from the last illustration published by Mr. Holt of the complete instrument, and which is the engraving, he says in his letter, does not represent the instrument he now uses!

"Since the above was written," he goes on to say, "a very great improvement has been made in the construction of the instrument, in my opinion so great as to get rid of every objection that could be previously urged against it. In the former instrument" (refers to the disowned illustration) "it was objected that there was no positive evidence that the instrument was in the bladder, and the objection was a valid one, *although, in the hands of an experienced surgeon, such a difficulty could hardly occur.*"

I have marked the latter part of the paragraph in italics, because these words prove, that Mr. Holt thought the instrument which he now disowns, sufficiently safe in the hands of an experienced surgeon; and therefore, as it was a reproduction of Perrève's dilator, he likewise must have thought Perrève's instrument a perfectly safe one in similar hands!

"But another objection," he writes, "was urged by some—viz., that it was possible for the tube to escape from between the blades of the dilator. This, also, as a *possibility* was true, but is now rendered quite impossible by the alteration that has been made in the handle; and as the dilator now acts as a catheter, and the tube cannot be displaced, the only objection that can possibly be urged is as to its introduction, and for this each individual operator must be responsible."—P. 7, *ibid.* This is what I suppose he alludes to in his second objection, by saying that in Perrève's instrument there is "nothing to prevent the tube slipping from between the blades." In this he is wrong, as not only is there the conducting wire, but also the safety clamps in their corresponding notches of each half of the handle, which are just as effectual for the purpose—indeed, in my opinion, more so—as Mr. Holt's new handle with its steady pins. Let the reader compare figs. 4 and 5, and judge for himself whether I am right or not.

Fig. 4.

Mr. Holt's new handle of dilator with steady pins. Wm. Oldham, Sep.

Fig. 5.

M. Perrève's handle of dilator with steady clamps. Wm. Oldham, Sep.

Mr. Holt's next statement is, that "although the principle" of his instrument "is the same as Perrève's, the detail is so entirely different as to have insured the use of" his "modification with almost universal success, while that of Perrève has been entirely abandoned." I have clearly proved that the details are not so entirely different as he represents, and as to Perrève's instrument being "entirely abandoned," this is a mere assertion without proof on Mr. Holt's part. He has not brought forward any evidence whatever to show, that the instrument had been ever prominently brought before the notice of the profession, or even used in the United Kingdom, and has not adduced one single well authenticated case of serious injury from a dilator constructed as Perrève directed.

Mr. Holt goes on to say—"Mr. Richardson has likewise alluded to the method of treatment, which here again is entirely different. Perrève did what Thompson is now doing, dilated

rapidly. I, on the contrary, am *never* satisfied without the stricture is split."

I have never denied that there is a difference between Perrève's and Mr. Holt's *usual* method of using the dilator; but his assertion "that he is *never* satisfied without the stricture is split," is not in accordance with what he says in his book:—"Hitherto I have only considered the applicability of the dilator, so far as rupturing or splitting the stricture is concerned, but it is *equally efficacious* where dilatation is desired, and possesses an advantage over every kind of bougie or sound in its power of dilating a stricture to any required extent *without being withdrawn.*" (*Ibid.*, p. 98.) "Having once introduced the dilator, its diameter can be increased to any extent the surgeon may desire; for this purpose *it is not necessary* that consecutive tubes" (forcers) "should be passed, as *by introducing at once* a No. 8 or No. 9, and very gently pressing the tube onwards, between the blades, they become separated to a considerable distance from the point of the tube." (*Ibid.*)

He continues to Mr. Smyly: "I conceive it to be a very great error to rapidly dilate strictures, and the quickness with which they re-contract when so treated justifies me in that conclusion." This appears to be approaching to another contradiction, for at p. 86 of his memoir, while speaking of the assumed advantage of his more rapid "splitting" method, he adds: "It is quite true that if the after-treatment is not attended to, the stricture will *sooner* or later recur."

Mr. Holt concludes his letter with the following observation: "Without wishing in the least degree to detract from the merits of Perrève's invention, I must assert that the instrument that bears my name is so far different from Perrève's, that in mine you have all the elements of success, while in Perrève's there are errors which have made its use unsafe, even in experienced hands." I have again to remind the reader that this is mere assertion; while Perrève, on the other hand, has recorded, that he used the instrument without fatal result in one hundred and fifty to two hundred individuals (*Traité des Rétrécissements organiques de L'Urètre*, p. 215, Paris, 1847) a success, by no means bad, from the use of an instrument which Mr. Holt says, has so many errors of construction; but which I have clearly proved is, with but one exception, practically identical with his "new stricture dilator!" and which he did not introduce to the notice of the profession until 1861.

To my mind, there could scarcely be found in our literature such an unacknowledged appropriation by one surgeon of the labours of another, as I have demonstrated with regard to Perrève's instrument.

Having now clearly exhibited the amount of obligation Mr. Holt has been under to M. Perrève's genius for the dilator which he uses, is it not, to say the least, ungrateful, for the former never to have alluded to the latter author, until the appearance of his letter to Mr. Smyly?

Not only has Mr. Holt omitted any allusion to M. Perrève, but he has introduced the "immediate method" of treatment in the following words, which speak for themselves:—

"The fatality that attends the uninterrupted course of a serious stricture, is but too certain. All practical surgeons are acquainted with the complications and suffering resulting from a disease, which, if taken in time, *is always amenable to treatment.* If, therefore, any means can be employed, by which all serious results can be obviated, and the treatment at the same time be made so simple as to be available by the majority of surgeons, it will, perhaps, be admitted that a step has been gained in the right direction. Hitherto I have not ventured to publish my experience of the plan I adopt, simply for the reason that it is injudicious to enunciate *any new method of treatment which has not been subjected to numerous trials.*" Again—"Up to the present time this method of treatment, though adopted by some surgeons, has been mainly confined to myself, simply,

I believe, from the fact that its general utility *never having been published*, it has not as yet been appreciated."

Lastly—"Being deeply impressed with the unsatisfactory nature of the prevailing methods of curing these distressing maladies, about seven years ago, I adopted a more energetic mode of treatment, and invited the attention of the profession to a new "*Stricture Dilator*." In effect—the same I have proved to be Perreve's, the theme of my communications.—I have the honour to remain, sir, your very obedient servant,

B. WILLS RICHARDSON

## FIRST EXAMINATION

FOR THE  
DEGREE OF BACHELOR OF MEDICINE.

OXFORD, DECEMBER, 1866.

### EXAMINERS.

GEORGE ROLLESTON, M.D.; AUGUSTUS VERNON HARCOURT, M.A.; ROBERT B. CLIFTON, M.A.; THOMAS K. CHAMBERS, M.D.; JOHN W. OGLE, M.D.; HENRY W. ACLAND, Reg. Prof. Med.

### NO. I.—PHYSICS.

1. Define a *lever*, and state its mechanical advantage. Into what classes have straight levers been divided? Describe the mechanism by which the human arm is bent and extended.

2. Describe the variations which the effective force of gravity undergoes in sustaining the motion of a simple pendulum.

How is the pendulum employed in determining the accelerating effect of the force of gravity?

3. Describe the common Hydrometer, and the method of using it.

4. When a fine tube open at both ends is dipped in a liquid, describe the principal phenomena observed, and state the laws which they are found to obey.

To what forces are these phenomena to be ascribed?

5. Describe the construction and action of a *free reed* organ pipe.

Explain upon the principle of the free reed the action of the human organs of speech.

6. Describe the structure of the eye, considered as an optical instrument, and trace the course of the pencils of light which produce the image on the retina, illustrating by a figure.

What is the nature of the defect known as *regular astigmatism*, what is its cause, how is it detected, and how remedied?

7. When plane polarised light, after passing through a tube filled with an aqueous solution of sugar, is plane analysed, what phenomena are observed?

Describe Biot's Saccharometer, and the method of using it for determining the amount of sugar present in diabetic urine.

8. Describe experiments shewing the conversion of work into heat (1) directly, (2) indirectly through electricity.

How much work must be done upon half a kilogram of copper (specific heat 0.095) in order to raise its temperature from 10°C to 20°C?

9. Describe any experiment which shews that when a liquid changes into a vapour heat disappears.

How is the latent heat of a vapour estimated? How has it been proposed to employ the absorption of heat attending the change from the liquid to the gaseous state as a means of destroying sensation in any part of the body, on which an operation is to be performed?

10. When a closed vessel containing a gas is heated at the bottom, explain how the gas becomes heated throughout.

In ventilating a room, at what places should the cold air be admitted? Give your reasons for your answer.

11. When a plate of copper and a plate of amalgamated zinc are placed in a vessel containing dilute sulphuric acid, state what takes place (1) when the plates are not connected, (2) when they are connected by a wire.

12. Describe Ersted's experiment as to the action of an electric current on a movable magnetic needle.

Explain the construction of Nobili's astatic Multiplier.

In physiological research should the Multiplier be constructed with a long or a short coil? Give your reasons for your answer.

### NO. II.—PRACTICAL CHEMISTRY.

1. Each of the tubes, *a*, *b*, *c*, contains a single substance.

2. Examine the solution *d* for iodine, and the solution *e* for morphia.

3. Prepare some carbonic acid gas, and determine approximately what proportion of this gas mixed with air is sufficient to extinguish the flame of a taper.

### NO. III.—CHEMISTRY.

1. In what relation do the chemical elements stand to the other kinds of matter on the earth's surface? Why are air and water, respectively, no longer regarded as elements?

2. By what methods may oxygen be prepared?

3. What are the sources and properties of ammonia?

4. In what metallic solutions does sulphuretted hydrogen produce precipitates in presence of an acid? How is this gas prepared?

5. What are the principal constituents of coal gas?

6. Describe the mode of preparation and properties of iodide of potassium.

7. How is phosphorus obtained?

8. Explain briefly the method of spectrum analysis, and state some of the discoveries which have resulted from its application.

9. How would you ascertain qualitatively the chemical composition of a tubercle?

10. Write a short account of the principal chemical changes to which the name fermentation has been given.

### NO. IV.—ANATOMY AND PHYSIOLOGY.

1. Give an account of the different ways in which the Nervous System may influence the functions of organic or vegetative life.

2. What do you know of the development, relations, and functions of the Eustachian Tube?

3. Explain an account of the origin, course, and functions of the chorda tympani, the buccal, the musculospiral, and the obturator nerves.

4. What are the physiological limits within which the size of the liver may vary, and what are the conditions which produce such variations?

5. Trace the course taken by the chyle from its formation up to the spot where it is poured into the blood-vascular system.

6. Enumerate the different muscles, membranes, and vessels which you would meet with in dissecting from the external integument down to the level of Cowper's glands.

7. Give some account of the organisms known as "Infusoria," "Vibriones," and "Bacteria." What relations have they been supposed by different authorities to hold to the production and to the products of Fermentation and Putrefaction?

8. Explain what is meant by the Botanical Terms "Stomata," "Primordial Utricle," "Cambium Layer;" and give a short history of the physiology of the sap.

9. What are the distinctive characters of the classes Vermes and Arachnida? Specify parasitic members from each of these classes.

10. What are the main points of difference and what the main points of interdependence existing between the Animal and Vegetable Kingdoms?

### NO. V.—ANATOMY.—PRACTICAL EXAMINATION.

1. Make such a dissection of the organ put before you as will enable you to demonstrate and describe the greatest number of its internal cavities and structures which are visible in one view.

2. Place under the Microscope some of the tissue of which the greater part of the organ you have dissected is made up; and state the points in which it differs from tissue bearing the same name in other parts of the body.

3. What does the Microscope enable you to predicate of the organisms contained in the jar labelled No. 1?

4. Write a description of the plants labelled 2, 3, 4, and give a short history of the Natural Orders to which they belong.

5. Describe at length the preparation labelled No. 5, specifying the functions which its several component parts perform in life.

6. Write a short description of the Museum-Preparations, Nos.

(To be continued.)

'THE Doncaster Dispensary is to be removed to the new infirmary on the 1st of May, upon terms to be arranged between the respective committees; but the two institutions are not to be amalgamated.

## Medical Obituary Notices.

### DR. W. MARSDEN.

THIS physician died on Wednesday week, worn out by a disease of long standing. Dr. Marsden established himself in practice nearly forty years since, at Thavies Inn, Holborn. He was the founder of the Free Hospital, in Greville-street, Hatton-garden, since removed to Gray's-inn-road, and known as the Royal Free Hospital. Dr. Marsden also founded the Cancer Hospital at Brompton, and was senior surgeon to both those institutions.

### DR. BRINTON.

WE regret to announce that Dr. William Brinton, F.R.S., died on Thursday last, at his residence, 24, Brook-street, London. Dr. Brinton had suffered for a long time past from disease of the kidneys, and his general appearance too clearly showed the existence of some serious malady. The acute symptoms which immediately determined the fatal result followed exposure to the cold in the late severe weather.

### DR. ARTHUR MITCHELL.

WE regret to learn that a further vacancy has occurred in the School of the Royal College of Surgeons of Ireland, by the death of Dr. Arthur Mitchell, which took place suddenly on Monday last. Dr. Mitchell had for many years filled the Chair of Botany in the Royal College of Surgeons, and as a Private Teacher in *Materia Medica* and Botany had contributed to the instruction of a large proportion of the Surgeons issuing from the Irish School. About twelve months since he was stricken with a severe attack of a cerebral nature, which, after comparative convalescence, has resulted in his decease.

### THE PALL-MALL GAZETTE TESTIMONIAL.

THE proposition which was started in our columns by Dr. Wilson, for a Professional recognition of the services of the *Pall-Mall Gazette*, has assumed a practical form in the letter which appears in our columns to-day. Great as the public services of the *Gazette* in this matter have been, they have done still more for our Profession in ventilating, with the great prestige of its independent opinion a crying abuse which would have received little attention coming from medical sources. Whatever form the gratitude of the Profession may assume, we trust it will be liberally displayed. Perhaps the most eloquent recognition would be a unanimous patronage of the journal by a permanent subscription from every medical man who feels the onus of thankfulness towards its proprietors. We shall most willingly co-operate in any scheme for this purpose.

## Medical News.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 15th inst., and when eligible will be admitted to the pass examination:—

H. W. Diver, T. J. Pickburn, H. C. Hopkins, F. L. Thorne, George Wilks, and D. K. Robertson, of St. Bartholomew's Hospital; Philip Thompson, Ratchiffe Nuttall, Charles Ogden, Thomas Wilson, and J. A. Giddings, of the Manchester School; T. J. Gittens, C. E. Wing, J. O. O'Brien, and J. P. Garlike, of Guy's Hospital; E. C. Gamble, and C. J. Rhodes, of the Leeds School; George Payne, and F. A. Helsdon, of Middlesex Hospital; T. C. Bailey, and R. L. Edgeworth, of the Dublin School; J. W. Pratt, and J. G. Anderson, of St. Mary's Hospital; John Casaden, and Titus Crooker, of Toronto; Julian Willis, of King's College; Frederic Smith, of London Hospital; J. E. Kenyon, of St. George's Hospital; Edwin Peacock, of Birmingham; and E. F. Chinery, of Edinburgh.

The following candidates passed their primary examinations on the 16th inst.:—

F. M. Wallis, G. T. Willan, F. W. Laslett, R. A. Painter, and A. W. G. Atkins, of Guy's Hospital; G. S. Walker, H. R. Moullin, W. H. Hubert, and W. E. Ledgard, of St. George's Hospital; J. J. Roy, H. D. Shelton, J. O. Sankey, and W. A. S. Blue, of St. Bartholomew's Hospital; R. D. Fox, and C. W. Calthorp, of Charing-cross Hospital; J. A. Williams, and E. J. Barrick, of Toronto; W. R. Davies, and J. B. Beavan, of University College; T. M. Watt, and W. A. Walker, of Belfast; G. W. Tacon, of London Hospital; W. H. Aston, of St. Thomas's Hospital; and Oliver Penfold, of King's College.

The following gentlemen passed the same examinations on the 17th inst.:

Charles Arthur Neason, of Guy's Hospital; John Levitt Davis, of the Charing-cross Hospital; Charles Turner Haddelsey, of the London Hospital; Henry Wintle, of Bristol; Henry Hemingway, of Leeds; and James Cornelius O'Grady, of Dublin.

It is stated that out of the 85 candidates who presented themselves for examination no less than 24 failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their anatomical studies for three months.

APOTHECARIES' HALL OF LONDON.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on the 3rd inst.:—

Nettleship, Edward, Kettering, Northamptonshire.

On the 10th inst.:—

Stainthorpe, Thomas Edward, Hexham Abbey.

Summerhayes, Henry, Ealing, Middlesex.

Williams, William Edward, Llanhilleth, Monmouthshire.

The following gentlemen also on the same day passed their first examination:—

Walter Hart, King's College Hospital; J. C. M'Donald, Westminster do.

THE cholera has disappeared from Carnarvon.

THE cattle disease still continues in the East Riding of Yorkshire.

AT a grand dinner recently given near Paris, the principal dishes were shark, horse, dog, and rat.

TWO men have been killed by sulphuretted hydrogen, from working in a tank containing sulphate of ammonia, at some chemical works at Bow.

AT the Kent Annual General Sessions, held last week, it was stated there are now 758 lunatics in the Maidstone Asylum.

REMOVAL OF QUARANTINE AT GIBRALTER.—Free *pratique* is allowed upon arrivals from Southampton with clean bills of health.

A FEW weeks ago a man arrived in Ararat (Victoria), with 28,000 leeches, which, in three days, he caught in a large lagoon.—*Sydney Herald*.

AT the weekly meeting of the City Commissioners of Sewers, on Wednesday week, Dr. Letheby reported that 1109 houses had been inspected during the past four weeks, that 155 places required sanitary improvement, that 12 out of 150 ships were found in a filthy condition, and that 14,222 lbs. of meat had been condemned as unfit for food.

TEN cases of the cattle plague have been reported by the official inspectors, and it would appear that the disease is still confined to one district—the East Riding of Yorkshire. Since the outbreak of the plague 253,817 animals have been attacked, while 52,656 healthy cattle have been slaughtered to prevent the spread of the disease.

THE Spanish frigate *Resolution* has put in at the Falkland Islands with upwards of one hundred cases of scurvy on board under treatment, and it is reported that thirteen of them had terminated fatally. This vessel had been engaged in blockading the coasts of Chili and Peru. It is also reported that all the Spanish vessels employed on that service had suffered greatly from scurvy, and had lost many men.

WE are informed, by one who ought to know, that last autumn a medical man of station drew the attention of the local police to a foul drain passing close by the house, at Wardie, of Mr. Alexander Smith, the poet, and assured them that cholera, diphtheria, or typhoid fever would prevail if it were not cleansed. It was, we believe, by one of these discreditable disorders that Mr. Alexander Smith has been carried off.—*Builder*.

A LAKE of borax has just been discovered in California; it is believed that the find is destined to revolutionise the important trade in that article. The Californians are turning their attention to the cultivation of olives, and boast that they can produce olive oil equal to that of Italy.

**FEMALE LONGEVITY.**—The obituary in the *Times* has lately exhibited some marvellous instances of prolonged existence in both sexes, but nothing in comparison with those which appeared on Wednesday last, where the deaths of seven ladies were recorded therein, whose united ages amounted to 612 years, and if to this number be added that of another woman whose death was reported the preceding day at 102 years of age, we have a total of 714 years, giving an average of exactly 89 years and three months to each, an amount of longevity perhaps unprecedented in the record of two consecutive days' obituary in this paper. On Thursday, the deaths of twelve persons were recorded—viz., three ladies and nine gentlemen—whose united ages amounted to 1030 years, giving an average of 85 years and ten months to each of these twelve persons. The oldest lady was 92, and the youngest 80 years of age. Of the opposite sex, one had reached 91, and the youngest 81 years of age.

A DEPUTATION from the Harveian Society will shortly wait upon the Home Secretary to lay before him the principal conclusions of their committee upon infanticide and infant mortality. The abolition of capital punishment for infanticide, and the substitution of various terms of penal servitude, the modification of the bastardy laws, the improvement of the workhouse maternity system, the registration of dry nurses, and the supervision of infant nurseries, are among the more important changes suggested.

THE *Moniteur de l'Hygiene* states that a number of sempstresses have been suffering from violent colics from putting they silk they use in sewing into their mouths. This is attributed to sulphate of lead, and the presence of that deleterious substance is explained by the fact that, as the silk is sold by weight, some manufacturers mix the sulphate with it to make it heavier.

## Notices to Correspondents.

*Dr. Maxwell.*—Your request shall have immediate attention.

*Dr. Owen Foz.*—A note has been made for January 27th.

*Dr. F. W. Mullar* is thanked.

*A. G. Heslitge Buckley, Esq.*—Thanks for your contribution in aid of the "sad case" in our advertising columns. It shall be forwarded as desired.

*C. Ede, Esq.*—Your communication shall receive immediate attention. *Mr. Hawskley's* note has been carefully considered.

*Dr. A.*—Opinions differ on this point, time alone will prove its efficacy. Pending certain inquiries, we think it unjust to criticize.

*Mr. J., London,* is referred to *Mr. Baker Brown's* note in our correspondence columns.

*Enquirer.*—The subject of "phantom tumours" is fully discussed in "Montgomery's Exposition of the Signs and Symptoms of Pregnancy," second edition, 1856. Longmans, Paternoster-row. There are other books in which the subject is mentioned, but probably in none so fully as this.

*Mr. Woolcott.*—It shall receive attention.

*Dr. Lade.*—The papers will be of no use.

*Dr. C.* is thanked.

## Appointments.

**BENNET, W. F., M.R.C.S.E.,** has been appointed Senior Resident Surgeon to St. Pancras Workhouse and Infirmary, vice *W. F. Butt, M.R.C.S.E.,* resigned.

**DAY, W. H., M.D.,** has been appointed an additional Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret-street, Cavendish-square.

**EVERETT, B. G., M.R.C.S.E.,** has been appointed Medical Officer for District No. 3 of the Chailey Union, Sussex, vice *W. G. Tiley, M.R.C.S.E.,* resigned.

**FITZGERALD, Mr. C. E.,** has been appointed Resident Scholar at Sir Patrick Dun's Hospital, Dublin, vice *Edgar,* deceased.

**GRAVES, C. A., M.B.,** has been appointed Visiting Surgeon to the Derby Union Infirmary and Workhouse, vice *J. Lindley, M.R.C.S.,* resigned.

**MOORE, C. H., F.R.C.S.E.,** has been appointed Visiting Surgeon to St. Luke's Hospital for Lunatics, vice *J. Luke, F.R.S., F.R.C.S.E.,* resigned.

**PATCHETT, H., L.R.C.P.Ed.,** has been appointed Medical Officer for the Billington District of the Blackburn Union, Lancashire, vice *J. Cannell, L.F.P. and S.Glas.,* resigned.

**PEARSE, Mr. G. E. L.,** has been appointed Demonstrator of Anatomy at the Westminster Hospital, vice *Mr. F. Teevan,* resigned.

**BITCHE, W. B., M.D.,** has been appointed to the Commission of the Peace for the Borough of Belfast.

**SEATON, D., M.R.C.S.,** of Oakham, Rutland, has been appointed Surgeon to the Rutland County Gaol.

**SINGLETON, W., M.D.,** has been elected Medical Officer to the Cappaduff Dispensary District, Co. Mayo.

**WARDEN, C., M.D.,** has been elected Honorary Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for the Diseases of Women and Children, vice *W. C. Orford, M.R.C.S.E.,* resigned.

**WOODHOUSE, T. J., M.D., F.R.C.S.,** has been appointed Assistant-Surgeon to the 1st Surrey Artillery Volunteer Corps.

## Vacancies.

Fulham Union—Medical Officer for Walham-green District.

Langport Union—Medical Officer for No. 3 District.

## Medical Diary of the Week.

### ROYAL INSTITUTION.

**TUESDAY.**—Jan. 22nd, at three o'clock, Professor Tyndall, "On Vibratory Motion."

**THURSDAY.**—Jan. 24th, at three o'clock, Professor Tyndall, "On Vibratory Motion."

**FRIDAY.**—Jan. 25th, at eight o'clock, Professor Odling, "On Mr. Graham's Recent Discoveries on the Diffusion of Gases."

**SATURDAY.**—Jan. 26th, at three o'clock, G. A. Macfarren, Esq., "On Harmony."

### HUNTERIAN SOCIETY.

**WEDNESDAY.**—Jan. 23rd, 7½ P.M. Special Council Meeting—8 P.M. Mr. Hinton, "An Outline of the Present Methods of Diagnosis and Treatment in Aural Surgery."—*Dr. Peacock,* "On the Diagnosis of Obstructive Disease of the Mitral Valve, with a Case."

### BOOK RECEIVED.

Hebra on Diseases of the Skin, &c. Published for the New Sydenham Society. 1866.

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

**FULTON.**—On January 19, at Saintfield, the wife of Thomas Fulton, M.D., of a daughter.

**HOUGHTON.**—On December 30th, 1866, at 6, Mount-street, the wife of Henry G. Houghton, M.D., of a daughter.

**WILKINSON.**—On December 24th, 1866, at Greenheys, Manchester, the wife of M. Eason Wilkinson, M.D., of a daughter.

**WORTHINGTON.**—On January 9th, at Worthing, Sussex, the wife of G. F. G. Worthington, Esq., of a son.

### MARRIAGES.

**THOMPSON—JAMES.**—On January 3, the Rev. Henry J. Thompson, M.A., of Dodford, Northamptonshire, to Sophia Mary, eldest daughter of Edward James, M.D., of Edgbaston.

**WAHLTUCH—GOLDSCHMIDT.**—On December 16th, 1866, Adolphe Wahl-tuch, M.D., of Manchester, to Anna, second daughter of H. S. Goldschmidt, Esq., of Frankfort-on-the-Maine.

### DEATHS.

**ATKINSON.**—On January 6th, at Great Marlow, Benjamin Atkinson Esq., Surgeon, J.P. for the county of Bucks.

**MARTIN.**—On January 7th, at Ventnor, Isle of Wight, George Anne Martin, aged 59.

**PICKTHORN.**—On October 21st, 1866, at Auckland, New Zealand, G. Russell Pickthorn, M.D., Assistant-Surgeon H.M.S. *Challenger,* aged 27.

**VISE.**—On January 6, at Spalding, Lincolnshire, Charles Vise, Esq., Surgeon, aged 64.

**WILSON.**—On January 8, at Ilkley, Yorkshire, James Wilson, M.D., of Malvern.

**FISHER.**—On January 17, at his residence, No. 5, Appian-way, Upper Leeson-street, Dublin, Thomas Fisher, Esq., M.D., Assistant-Librarian Trinity College, aged 66 years.

**JENINGS.**—On the 17th ult., T. Jennings, M.R.C.S.E., late of Denbigh-street, Fimlico, aged 54.

**Ross.**—On the 31st ult., J. T. Ross, M.R.C.S.E., late Assistant-Surgeon Royal Naval Hospital, Simon's Bay, Cape of Good Hope.

**EDGE.**—On the 1st inst., at Sir Patrick Dun's Hospital, Dublin, Mr. G. B. Edge, one of the resident pupils, aged 22.

**BELLIS.**—On the 9th inst., Benjamin Bellis, M.R.C.S.E., of Kidwell's-park, Maidenhead, aged 60.

**BLICK.**—On the 9th inst., at Islip, Oxfordshire, Thomas Curle Blick, M.R.C.S.E., L.S.A., aged 67.

CLINICAL LECTURES  
 DELIVERED IN  
 STEEVENS' HOSPITAL,  
 TOGETHER WITH  
 OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,  
 PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,  
 PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
 SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

(Continued from page 73.)

REMARKS ON CHLOROSIS AND HÆMORRHAGE.\*

THE following general remarks on chlorosis and hæmorrhage were suggested by some cases of these diseases which were treated in the medical wards of Steevens' Hospital during the last session.

Chlorosis is an affection of frequent occurrence and great interest; and though it has been repeatedly investigated by several distinguished pathologists, many points of considerable importance in its history yet remain to be explored and explained. We shall retain the name chlorosis as, perhaps, the best we can adopt; it is, doubtless, one derived from a symptom, yet a symptom so invariably present that it sufficiently designates the disease. This is not the only instance in which we deem it necessary or convenient to employ the name of a symptom, as expressive of the disease which gives rise to it; we may cite for example, jaundice, dropsy, and paralysis. It is sometimes better to retain even an objectionable word than to encumber science with new and often uncouth terms. We shall not speak of chlorosis as synonymous with anæmia; the former refers to a specific disease, the latter bespeaks a state of the system, either general or local, which may arise during the progress of several diseases; it was introduced into our vocabulary by the eminent physician Andral, and (though not etymologically correct) is too useful and convenient a term to be parted with. There are many cases of chlorosis marked rather by an increase than a diminution of the total amount of the circulating fluid. In chlorosis there is a change in the quality, but not necessarily a change in the quantity, of the blood; so that chlorosis must be looked upon as a peculiar and distinct disease, and not identical with anæmia. In like manner hyperæmia is a convenient term to express a surplus of blood, generally or locally, but it is not expressive of any particular disease; and in speaking of hæmorrhage in contrast with chlorosis, as we propose to do, it is necessary to draw a marked line of distinction between hæmorrhage—which sometimes arises even when general anæmia exists—and the state of hyperæmia.

It has been already remarked that there is no proof of deficiency of blood in chlorosis; on the contrary, there is strong presumptive evidence that an actual excess of blood, though of inferior quality, characterises some cases of the disease; and it is worthy of remark, that in the treatment of chlorosis, the moderate abstraction of blood by the lancet, by leeches, or by cupping, not only does not aggravate the symptoms, but so far from this, when incidental affections demand depletion, is followed by the best effects. The disease in reality consists, not in a diminished quantity of blood, but in an altered quality—a diminished consistency of this fluid; herein lies its very essence, and any term which signifies the former, not the latter condition, is at least objectionable as applied to chlorosis. In chlorosis the blood undergoes a very remarkable change; its specific gravity is lowered; the clot is small and firm; the serum bears too large a proportion to the crassamentum; water is in excess; the red corpuscles are far below the

healthy standard in quantity; their appearance, however, under the microscope, is natural; and the fibrin, in the majority of cases, is normal in quantity, firmness, and cohesive power.

In hæmorrhagic diseases, the chemical and physical characters of the blood are very different. Its specific gravity is seldom much below, and occasionally even exceeds the healthy standard; the separation into clot and serum is imperfect, and the clot bears too large a proportion to the serum; the quantity of fibrin is less than in healthy blood, or, at least, its proportion to the red corpuscles is less than is found in a state of health; the quantity of red corpuscles is either absolutely increased, or their proportion to the fibrin is larger than in healthy blood; and the quantity of solid constituents frequently exceeds that of the normal fluid. The clot is, in general, large, soft, and of a dark red, or almost black colour; sometimes the formation of a clot does not take place; a buffy coat is scarcely ever observed, except when fever or inflammation is present; and the serum is frequently tinged with red by the presence of red corpuscles in suspension. Under the microscope, the red corpuscles are most commonly seen of small size, with their edges lacerated and irregular; mingled with these are numerous shrivelled, apparently empty, colourless cells, the walls of which are of extreme delicacy.

These facts respecting the characters of the blood in chlorosis and hæmorrhage are established by the well-conducted experiments and accurate analysis of Andral, Gavaret, Denis, Lecanu, Simon and others; and have been corroborated by numerous observations made in the hospital by Dr. Hill, under my own superintendence.

The following briefly noted cases will, on comparison with each other, serve to illustrate the distinguishing characters of chlorosis and hæmorrhage:—

Mary Callaghan, aged 17, a domestic servant, of middle stature, spare habit, and chlorotic appearance, was admitted into Steevens' Hospital, August 2, 1845. The integuments are of a sickly white, waxy hue with a slight tinge of yellow on those parts which are most exposed to light. The extremities are habitually cold and moist, especially the feet, which, she says, are never warm. She complains chiefly of constant frontal headache; pain, with tenderness on pressure in the hypogastric region, chilliness, languor, and weakness in the back. The tongue is pale and moist, the appetite delicate, nausea frequent, and bowels always confined. Respiration performed twenty times in a minute; no cough nor pain in either side, and the respiratory sounds healthy. Pulse 96, feeble; heart's action tranquil whilst she is at rest, but any sudden exertion or emotion produces violent palpitation. The first sound of the heart is accompanied by a loud, rough *bruit*, which varies much in intensity at different periods, and under different circumstances of excitement, but has been present, more or less, at every examination. There is no evidence of hypertrophy of the heart, nor can any murmur be detected in the arteries or veins. There has been no appearance of the menstrual discharge for the last eight months, previously to which time it was always regular, and she is unable to account for its cessation. She has never suffered from leucorrhœa, nor observed any tendency to œdema in any part of the body.

Urine is passed in natural quantity; is of pale, limpid appearance; specific gravity at 64° Fah., 1008; faintly reddens litmus paper, and is free from albumen. She states that, notwithstanding the derangement of the uterine functions, she enjoyed tolerable health until four months since, when she began to suffer from headache, nausea, and general debility. Four ounces of blood were taken from the arm, and the following observations made:—

Temperature of atmosphere . . . . .	64° Fah.
"    under the tongue . . . . .	100° "
"    in the axilla . . . . .	95° "
"    of blood as it flowed . . . . .	97° 5' "
Specific gravity of blood at 75° Fah. . . . .	1.031.
Specific gravity of serum at 64°, Fah. . . . .	1.025.
In 1031 grains of blood,	
The weight of serum was . . . . .	760 grains.
The weight of the clot, . . . . .	271 "

\* The Dublin Quarterly Journal of Medical Science, Nov. 1st, 1846. Reported by John Hill, A.M., M.B.

being in these proportions of 1000 to 356.5. These proportions were taken twelve days after venesection.

The blood, when flowing, seemed nearly as thin as water, and was of a bright florid colour, resembling that of arterial blood. The clot was very small, firm, of a dark reddish colour, and without any appearance of buffy coat. The serum was transparent and colourless. Under the microscope the characters of the red corpuscles were normal.

P. Conolly, aged 22, a weaver, of spare habit, but florid complexion, was admitted into Stevens' Hospital, July 17th, 1845. The entire surface of the body, excepting that of the face, hands, and feet, is thickly covered with brownish red petechiæ, mingled here and there with small, more deeply seated, and dark coloured ecchymoses. At the upper part of the forehead are several broad red patches, covered with furfuraceous scales. The gums are soft, spongy, of a purple colour near their junction with the teeth, and bleed freely whenever he masticates any hard substance. The tongue is clean and red; no petechiæ are observed within the mouth. He is very subject to epistaxis, a severe attack of which, two days ago, induced him to apply for admission into hospital. His appetite is good, and his bowels usually regular, but at present they are confined; in other respects his general health appears unaffected. Pulse 76; heart's sounds normal. Respiration 18 in the minute. He states that, during his childhood, he was occasionally subject to epistaxis, and that, about seven years ago, he first observed a number of small red spots upon his arms, which he, at that time, mistook for flea bites; these spread in successive crops all over his body, and shortly afterwards he became subject to frequent hæmorrhage from the nose, gums, and bowels. He says that the spots fade and die away sometimes, but that, ever since their first appearance, he does not remember having been totally free from them for more than a few weeks at a time. Previously to the commencement of the disease he was in very distressed circumstances; of late years, however, he has been able to earn a comfortable subsistence. Four ounces of blood were taken from the arm:

Temperature of the atmosphere . . . . .	63° Fah.
"    under the tongue . . . . .	97° "
"    of blood as it flowed . . . . .	98° "
Specific gravity of blood at 64° Fah. . . . .	1.054
"    of serum at 64° " . . . . .	1.027
In 105½ grains of blood,	
The weight of serum was . . . . .	238 grains.
The weight of the clot . . . . .	816 "

being in the proportion of 1000 to 3428.5. These proportions were taken twelve hours after venesection. The blood, as it escaped from the vein, appeared thin, and was of a florid red colour. The clot was very large, soft, black, and soluble in water. The serum held a great number of red corpuscles in suspension. Under a high magnifying power, the recent blood exhibited a great number of ruptured corpuscles; their general size was, however, normal. In a drop of the tinged serum were seen numerous red corpuscles, of which about one-fourth were of natural size and appearance; another fourth were of natural size, but with lacerated edges and irregular surfaces; whilst the remaining two-fourths were of small size, not exceeding the dimensions of the central nucleus of a normally-sized red corpuscle. There were, in addition, numerous thin, membranous cells, empty and corrugated, floating in the serum.

These cases exhibit in strong contrast the characters of the blood in the chlorotic and hæmorrhagic conditions. They are extreme cases, and are given as such; in other instances which we have examined were observed degrees of contrast, from the minutest shade of difference to the extreme amount now portrayed. The most striking distinctive character is in the specific gravity of the blood; in the chlorotic case it was 1031; in the hæmorrhagic case 1054; but there are other remarkable differences, and these are at once recognized by a reference to the examination made. We do not profess to give a minute chemical analysis of the blood; our object is to mark the prominent and distinctive characters in each condition of the

blood, and thence we hope to arrive at useful practical deductions.

From the pathological state of the blood which characterises chlorosis, many interesting phenomena spring; upon these, in succession, we shall make a few observations and practical remarks.

The first important symptom which we shall notice, as a consequence of this imperfect sanguification—is this deficiency of the red corpuscles—is the low degree of animal heat. Well-marked chlorosis is distinguished by an universal chilliness; the extremities are, in many cases, insuperably cold; and scarcely are they warmed by exercise or artificial heat till (the loss by radiation and evaporation not being supplied by the blood) they again become destitute of animal heat. Even in bed this coldness of the extremities remains for hours, and prevents sleep. Sometimes they are deadly pale and dry; at other times swollen, livid, and clammy; but in either case they are characterised by a very low degree of temperature. The whole condition of a chlorotic patient in many respects resembles that of a cold-blooded animal. There exists also a marked incapability to bear extreme ranges of atmospheric temperature. So long as the blood continues in the deteriorated state which constitutes the essence of this affection, the individual ceases to possess that power of adaptation to climatic extremes which distinguish the human race. To such persons summer heats and winter colds are distressing and intolerable; they thrive best in a dry, invigorating, and moderately warm atmosphere; and their sufferings would be much mitigated were the air they breathe always of an uniform and medium temperature. In the treatment of chlorosis much advantage is derivable from remedies capable of supplying this deficiency of animal heat: for example, from warm pediluvia, frictions, shower-baths, and such covering of the body as shall not debilitate, and yet prevent the too rapid escape of caloric by evaporation or radiation; but above all, from well-regulated exercise, both equestrian and pedestrian, not exceeding the then existing physical powers, but gradually augmented as these powers by habituation acquire force. To these should be added, when practicable, travelling and daily quick transitions through the air, as in an open carriage, so as to stimulate the lungs, and improve the respiratory and circulating functions.

The importance of this mode of treatment is shown by the following observations, quoted from Simon's "Animal Chemistry":—"When there is a paucity of corpuscles, the necessity for the absorption of oxygen is diminished in a corresponding ratio, the circulation becomes slower, and there is less heat developed than in the normal state; on the other hand, blood with an excess of corpuscles, but which is circulated slowly, develops less heat than blood which contains a smaller proportion of corpuscles, but which is more rapidly circulated, for more oxygen may be consumed in the latter than in the former case."

The production of animal heat is unquestionably much influenced by the rapidity of the circulation, as well as by the quantity of blood corpuscles. Of this we may convince ourselves by a reference to the researches of Prevost and Dumas on the relation between the mass of corpuscles and the temperature in various animals. For instance, in the goat the amount of blood corpuscles is considerably less than in man; but the temperature of the former exceeds by four or five degrees that of the latter. This may be accounted for by the fact that, in the goat, the pulse is, by ten or twelve beats in the minute, quicker; and respiration, by six in the minute, more frequent, than in the human subject.

Becquerel and Breschet have also ascertained, by means of a thermo-electric multiplier, that each contraction of a muscle is accompanied by an elevation of temperature amounting in some instances to 2.6°. In this manner we may, perhaps, account for a portion of the increased temperature that succeeds active exercise.

When the blood has undergone the morbid changes described, when the red corpuscles are deficient and animal heat imperfectly supplied, it follows as a necessary consequence that the nervous and muscular systems, being sup-

plied with deteriorated blood, should exhibit in their functions a corresponding degree of depression. If this be closely investigated, and due allowance made for the different degrees of activity which belong constitutionally to different individuals, it will appear that in every real case of this disease, there is a varying amount of energy abstracted from the brain, nerves, and muscles, and indicated by languor of mind and lassitude of body. To form a correct estimate it must be founded on comparison of what the individual had been in health, and now is when labouring under chlorosis. In the severer and more advanced forms of the disease the contrast is most striking.

There are two remarkable symptoms which, to a greater or less extent, are, I believe, always present in chlorosis, namely, palpitation of the heart and dyspnoea, on making exertions such as in health would be utterly incapable of producing these effects. In many cases the palpitations produced by ascending even a few steps of stairs are exceedingly distressing; in some instances the dyspnoea is the more urgent symptom; they are, however, generally found to co-exist and to be caused by very slight muscular exertions and mental emotions. The varied disturbances of the heart's action constitute a very prominent symptom; nor is this opposed to what we might anticipate when we consider how much altered are the constituents, and consequently the stimulus, of the circulating fluid. We also find that the pulse is often quick, small, and weak; for, though the contractions of the heart occur in rapid succession, the blood wave propelled at each systole is diminished and powerless. In an early stage of the disease, when the patient is quiescent, the pulmonary and cardiac motions are tranquilly and often languidly performed; the heart and lungs, however, partaking of the general enfeeblement, and receiving and circulating an impoverished blood, exhibit signs of hurried action and disturbance when even a very slight amount of augmented labour is exacted from them. But when the chlorotic affection is further advanced, when the general torpor is increased, and the blood reduced to a very low degree of attenuation, then the breathing and the pulse become permanently disturbed and quickened.

To the same sources may be referred the derangement of the assimilative function—the diminished appetite, the slow performance of digestion, and the inactivity of the intestines. The constipated state of the bowels is a very constant symptom; it has even been asserted that purgatives alone are capable of curing the disease. That they are in many cases useful, often highly so, experience has fully established; the assertion that they are to be solely relied upon, all experience contradicts. In a very large proportion of cases the first curative step is to evacuate thoroughly the intestinal canal; and to effect this purpose such medicines should be employed, assisted by enemata, as will insure sufficient action of the bowels without depressing the vital powers. Cases of chlorosis occasionally occur in which diarrhoea, or a tendency to it, prevails; these, however, are exceptions to a general rule, and may be traced, in the majority of instances, to constitutional predisposition, to unwholesome, indigestible food, or to atmospheric vicissitudes. Diarrhoea is not properly a symptom of the disease. The more the respiratory functions and the condition of the blood are improved by appropriate treatment, the more certainly will the appetite and intestinal actions be approximated to the normal state. The diet best suited to a chlorotic patient merits consideration. The appetite and digestive powers being enfeebled, it is necessary that the quantity consumed at each meal should not exceed the assimilating powers of the stomach; the food should be well masticated, and consist in articles of diet most highly nutritive. In some there is a distaste to solid animal food; then the substitutes provided should contain in small bulk as much nutritive matter as possible, that thus the object in view—to enrich the blood without overloading the stomach—may be attained. When the stomach can receive and digest them, tender, old, and gravy meats, and game, claim a preference. In regulating the diet of the chlorotic patient, much stress should

be laid upon the necessity of supplying animal heat more abundantly. It should then be the opposite of that which in tropical climates is provided by nature, and more in accordance with that used in cold climates; hence articles of food abounding in carbon, such as butter, cream, oil, and fat, should be mingled with the daily food, in quantities not exceeding that which the stomach is fully capable of digesting. For the same reason, unless forbidden by some constitutional peculiarity, good wine, and brandy and water, should be liberally allowed; porter and ale suit some individuals better, and attain the same object. These are the cases in which I have seen the most decided advantage from brandy and new milk taken early in the morning; in many such cases too the *Oleum Jecoris Aselli* has been particularly beneficial. The diet then in chlorosis should be so regulated that, without oppressing the stomach, the blood may be enriched and animal heat promoted.

(To be continued.)

## Original Communications.

### A CASE OF RESUSCITATION AFTER TWO HOURS' APPARENT DEATH BY DROWNING,

OCcurring IN THE LATE CATASTROPHE AT REGENT'S-PARK.

By JOHN DENNAN, Esq.

On the afternoon of Tuesday, the 15th instant, about a quarter past four, I received, in the absence of Mr. Obré, a summons to view a dead body just withdrawn from the ornamental waters in Regent's-park.

While on the way I entered somewhat minutely into the particulars with my guide, and on my arrival determined to examine the subject very carefully.

The man was apparently *quite dead*, and I heard the following statement, viz.:—that he had left his abode in perfect health, and joined in the general amusements on the ice, and was one of those at some distance from the shore when the catastrophe occurred. I particularly observed that the patient was intensely cold, from having been immersed some minutes, and having struggled in the water for more than half an hour. There was neither breathing or heart's action, the pupils dilated, the jaws clenched, and the limbs contracted, so much so that the clothes had to be cut off before anything could be done to the patient.

A frothy mucus covered the mouth and nostrils, the body was much swollen and I had it placed on an incline at an angle of about 35°, as the body was so very cold. I commenced, with the assistance of the two men who brought him home, to try to restore warmth by degrees, rubbing the chest and limbs thoroughly and swiftly with ice and snow, cleansing the mouth and nostrils from time to time, and adopting Silvester's method of artificial respiration for more than two hours. After a quantity of frothy mucus was discharged slight signs of animation were perceptible though so faint that I almost despaired.

I then had him well wrapped in blankets, placing large tins of hot water at the feet, and mustard poultices on the chest, while the body was well rubbed with warm flannel under the blankets. I continued this treatment for three-quarters of an hour, at the same time continuing to imitate the movements of breathing. A decided improvement then took place. The patient's jaws relaxed, and he appeared to breathe more freely. I then administered two teaspoonfuls of warm water, which caused him to vomit slightly. As soon as he commenced breathing freely I was able to give him a little warm tea, which he apparently relished. I may here observe that I could not induce him to take spirits.

The patient was now placed in a warm bed prepared for him, soothed to sleep, and all undue excitement prevented.

The patient was feverish for one or two days, but on the following Friday I had the pleasure of receiving a visit from him.

## FARADIZATION AND GALVANISM.

By W. H. SANDHAM, M.R.C.S.

READING the cases of partial paralysis and hemiplegia, published in THE MEDICAL PRESS AND CIRCULAR of the 14th Nov., 1866, by Dr. Althaus, of the London Infirmary for epilepsy and paralysis, and a case of lead paralysis, successfully treated by Professor Banks, of Sir Patrick Dun's Hospital, led me to the following remarks and report of a few cases successfully treated by me:—

It is time that gentlemen reporting cases treated by Faradization or Galvanism should, for the benefit of the initiated, and in order not to mystify, and so mislead students of medical electricity, be more minute and explicit in stating the instrument and the exact current used.

Faradization, for instance, may be effected by an electro-magnetic, a magneto-electric, a friction, or a galvanic battery. That is not all, it may be produced by an inverse or a direct intermittent current from any one of these batteries, and they may be applied with one pole on the spine, and another on any part of the body, or one pole at the origin of a nerve or muscle, and the other at the peripheral extremity of the former on the centre or insertion of the latter. I have given the treatment of disease by electricity some study, yet I am often at sea as to the instrument, the current, or the mode of application used in, I may say, most of the cases reported; so that future reports of cases would be far more valuable were the reporters more particular in naming the instrument, the particular current, and the mode of application.

## HEMIPLEGIA.

I treated a lady lately who fell down suddenly in her bedroom, and was taken up hemiplegic on the right side. Her arm was permanently flexed to an acute angle, the fingers almost stuck into the palm, her leg powerless, and foot so clubbed that when on the ground it rested on the outer edge; muscles of the face and tongue unaffected; sensation and heat of the whole side normal, or rather more than the opposite side. She was treated by various medical gentlemen, and twelve months after the first attack I was consulted. The muscles of the superior extremity were much wasted, and in the flexed position described, while the inferior extremity was so swollen and œdematous that from the thigh down was one shape, it could only be moved by her attendant. On the third application of the inverse interrupted current of the primary wire of an electro-magnetic apparatus, I could, with the greatest ease, extend the forearm and fingers at pleasure. The leg continued longer insensible to the current, but this too improved rapidly; the œdema of the limb entirely disappeared, and she could now lift it and make a kick at you herself. I used the interrupted current, and the continuous uninterrupted current of a galvanic apparatus on alternate days. The muscles of arm and leg became defined, as the lady herself used to say, "This arm is now more plump and round than the other." But at this stage of progress, some kind friends, who possessed too much brains, interfered, and she gave up the treatment, all because she suffered a little severely during the application of the interrupted current—notwithstanding the evident improvement. While treating this case I was forcibly struck with the idea—in fact, convinced—that in such cases as the one described, we come to the conclusion that one half the body is paralyzed, but I now think this a very erroneous diagnosis. Take the arm in this case: it is permanently flexed from the moment of the fall. Is this evidence of paralysis? Nay, rather evidence against it; for after passing an interrupted current for a few minutes along the extensors, I could extend or flex the limb and fingers at pleasure—proving either that the extensors alone were paralyzed, or that the flexors were permanently flexed by spasm, caused by spinal irritation without paralysis of the extensors at all; the current at all events either suppressed the spasm or restored the paralyzed extensors, so that the one antagonized the other, as in health. I am now disposed to think this was not a case of

paralysis at all, but a state of parts produced purely by spinal irritation. The lady's intellect, speech, sight, digestion, and circulation, were healthy. I think this view of helpless limbs much overlooked, and very suggestive to a thinking mind. I here put this idea before my medical brethren, in hopes others may reflect thereon, and give us their experience; for so forcibly struck was I by this case, that I conclude we often arrive at a wrong conclusion, when on seeing one who has lost the control of a limb or the power of locomotion, that paralysis is always the cause, when permanent spasm, consequent on spinal irritation or injury at the origin of a nerve, may be the cause.

## DISTRESSING FACIAL NEURALGIA.

Over a month since a Cork gentleman consulted me. He had most acute facial neuralgia of right side; sometimes it was intense in the temple, sometimes in the upper, sometimes in the lower jaw, and again immediately in front of the ear. It commenced about nine months ago. He did everything that was recommended to him; among the rest he took ten dozen of quinine pills, used liniments, mustard, and other plaisters, stupes, &c. At length he was recommended a sea trip, and so anxious was he to get well that he forsook his business, and at considerable loss and expense sailed for Rotterdam; but he suffered all the way, and returned as bad as ever, when some party who I before cured recommended him to me. I treated him with a direct continuous galvanic current along the three branches of the fifth nerve. The very first application afforded relief, and after a week's treatment (daily application) he said "that he had not such a week for months." I repeatedly asked him had he any bad teeth on that side. His reply always was "No." But conceiving I used to hunt, as it were, the pain into or by the side of two teeth, I came to the conclusion something was there wrong that again lit up the neuralgia after I had removed it, and I discovered that when a cold body touched near the teeth a pain shot through them, and so lit up the neuralgia again. I gave my opinion that unless two small teeth were extracted I could not permanently cure the neuralgia. He consented, and with a key instrument, along which I conducted a galvanic current for about five minutes, I lugged out the two teeth at once. I applied galvanism on two successive days, so that after nine applications he continues well to this date. His own words are—"I am in Heaven." No medicine whatever administered.

## FACIAL NEURALGIA OF THREE MONTHS STANDING.

Mrs. C—y, Cork, came to me after three months' intense suffering from facial neuralgia, for which she had been treated by several medical men. When I first saw her the side of the face and about the ear was greatly swollen, and profuse purulent discharge from the ear, with intolerable pain in side of face. I used a direct continuous galvanic current daily for a week. The first application removed all acute pain, and the swelling and discharge rapidly disappeared. She continues well to this hour. No medicine given.

## SEVERE LUMBAGO OF THREE MONTHS' STANDING.

Mr. M—, Cork. After three months' suffering from lumbago, consequent on spinal irritation, during which time all that the ingenuity of his intelligent physician could suggest was tried, he sent for me. After the fifth application of a direct continuous galvanic current, and without the aid of any medicine whatever. On the fifth day he was able—free from pain—to be out of bed, and to attend to his business; and after the ninth application I left him well, and he still continues so; this is now several months past. But to enumerate the number of cases successfully treated by me in Cork would be tedious and unnecessary after the many already reported by me in THE MEDICAL PRESS AND CIRCULAR, and the *Electrician*. Suffice it to say, that electricity as a therapeutic agent, scientifically administered, cannot any longer be neglected; and I am astonished beyond measure, in the face of the vast mass of evidence

in its favour, that a single medical man can be found bold enough to ignore it in the present day, but it is only those who are unacquainted with what it is capable, venture to do so. Lately, in consultation with two medical gentlemen, in a case where the patient had not a half hour's real sleep for a couple of months (notwithstanding that one of them tried a large proportion of the drugs in the Pharmacopœia to produce it), and was suffering from intense dyspnœa, owing to pure spasm of the respiratory muscles. On proposing galvanism one of them replied:—"Oh! it hurries the circulation too much." The other—"Oh! it stimulates too much," &c., &c. Still I persevered, and galvanism allayed the dyspnœa, and secured a sleep that lasted from eleven o'clock P.M. to nine o'clock A.M., next morning. Surely this was not a coincidence: did sleep follow because three medical men met in consultation? Certainly not. I look upon electricity as so important an agent in the treatment of disease, that were I one of the court of examiners attached to any of the universities, I would reject any candidate for a medical or surgical degree who could not give evidence of his having well studied electricity as a remedy in disease.

## Hospital Reports.

### GUY'S HOSPITAL.

#### SYPHILITIC DISEASE OF SKULL; PARALYSIS OF PORTIO DURA; ABSCESS OF MASTOID PROCESS; ABSCESS OF LUNGS.

(Under the care of Mr. HINTON.)

MARY B., aged 28, married, pale and cachectic, was admitted into Guy's Hospital, under the care of Dr. Rees, on the 19th of July, suffering from febrile symptoms, deafness, and indications of abscess behind the ear. She was ordered carbonate of ammonia, with lemon-juice, to be taken during effervescence, and transferred to the care of Mr. Hinton, who saw her on the 25th, when she gave the following history:—

She had no children. Eight years ago suffered from syphilis, and probably again since that date. When a child remembers falling two or three times into a cellar, and being stunned; but since then felt no ill effects until about two years ago, when she became deaf in the right ear, and paralysis supervened. Nevertheless, there was neither pain nor discharge at that date; both these symptoms came between nine and ten months ago. On the appearance of the discharge the paralysis recovered, and on its cessation returned, but went away again on the removal of the discharge. Considers she has been deaf for two years. Still suffers at times from pain in the ear, and a great singing noise, but this is not constant. Has noticed this particularly for the last nine months, and is quite sure it was not present when she became deaf two years ago. Considers her left ear all right. She relates three severe fits, with foaming at the mouth, &c., but has had none since the discharge began, though just before that she had "had fits" every day. The discharge first began when she was lying down; it burst suddenly—"went off like a cannon, and blood and corruption came." For three months before this the pain had been very intense.

About a month ago a medical man had ordered a blister, which was kept on six hours. She had overworked herself, and suffered from very severe pain in the forehead and vertex. She felt weaker after the blister, and continued to get worse until she obtained admission to the hospital. A little while before being admitted had coughed up blood. Her family is not unhealthy. She belongs to a family of nine. Two of her brothers have had affections of the ear.

At this time (25th) the hearing distance of the left ear was six inches. The *membrana tympani* was healthy, and rather pale. The click of the nail was heard by the right ear when quite close. The membrane of this ear was nearly

in appearance, and perforated; the air passed freely through it. There was no redness nor swelling around, but considerable tenderness was detected behind the ramus of the jaw. The discharge was profuse, and very fetid, with all the characteristics of that arising from diseased bone. The throat was healthy, but the mucous membrane unusually pale.

She was allowed nourishment, and six ounces of wine daily.

℞ Linimenti ammoniæ, ℥vj.  
Chloroformi, ℥ij. M. Fiat. lin. \*  
℞ Liq. potassæ permanganatis, ℥xx.  
Aquæ, ℥j. M. Fiat. lotio.

27th. The lotion has partially removed the fetor of the discharge; the liniment has produced a little redness; no change.

30th. Much worse; seems quite prostrate; a good deal of low fever; pulse 108; cough has come on again, with purulent but not fetid expectoration; discharge from the ear now consists of thick pus; there is fulness below and just behind the ear, with tenderness on pressure; has had cold shiverings six or seven times during the day; the discharge seems much increased; she blows through easily; there is no redness, neither is there tenderness on syringing; has some pain inside the head and on the top.

A free incision was made over the mastoid process, at the inferior part; the skin was very thin; the bone was not rough; no blood flowed, except from the lowest portion of the incision; linseed-meal poultices were ordered.

31st. Complains of pain in the right side of the chest, and has again spat a little blood.

The click of a nail can now be heard at a distance of two or three inches, and she thinks she is getting her hearing again, which she has not had for years.

August 3rd. The pain in the head has been much less; the incision healed at once; there is still tenderness over the mastoid process; to-day she had a severe rigor, and says it was like she used to have when her cough was very bad.

4th. Discharge as profuse and offensive as ever; no change in the appearance of the ear; the water used to syringe it passes out through the nose; she can now hear the click of the nail at twelve inches distance; no paralysis of the face. She had discovered that on pressing behind the ear in a certain way she could force out the matter. Pressure, not over but behind the mastoid process, directing the finger upwards and forwards, produced a stream of thick pus, running two inches down the neck, and this without causing her much pain.

The mist. conii of the hospital pharmacopœia was ordered to allay her cough.

5th. Pressure in the same spot still forcing out pus of the meatus, an opening was made, and between three and four ounces of fetid pus evacuated. The probe passed in inferiorly to the distance of an inch and a-half, and a little roughness was perceived on the bone. A poultice was applied. The water employed in syringing the wound did not escape at the meatus; nor on blowing with meatus closed did air escape through the wound.

8th. Weaker; gradually sinking; no rigors since last account; local symptoms continue much the same; there is much discharge both from the meatus and the opening; not much tenderness; exhaustion, in fact, has set in. She died without further pain.

*Post-mortem.*—On removing the calvarium it was found to present numerous nodosities, probably of syphilitic origin, as shown by the history. The cerebrum was healthy. The dura mater covering the right lateral sinus was discoloured. The cerebellum in contact with it was also discoloured to the depth of about half an inch. Beneath the microscope there were found in this part very numerous free cells of small size, partly altered blood globules and partly pus cells, no large granule cells. The lateral sinus contained firm adherent clot, and the blood was coagulated in several adjacent vessels. The part of the jugular vein immediately connected with it, contained several firm and

altered clot and was thickened; lower in the neck it was healthy. In each of the lungs were several abscesses, containing offensive pus and some of them involving the pleura. Their structure generally soft and infiltrated. No abscess found in any other part. It may be here remarked that the patient died with symptoms more resembling phthisis than those of secondary inflammation.

Shortly before the case took so rapidly fatal a turn, the question of opening the mastoid process was raised.

On examining the right petrous bone it was found to be destroyed for a space of an inch and a-half by three-quarters of an inch, in the situation of the lateral sinus and jugular fossa and in the cavity was contained a *sequestrum*, about the size of a hazel nut, and of an irregular form. The soft parts around were sloughing. The mastoid process was reduced to a mere shell of bone about two lines in thickness, and its posterior surface destroyed. There was free communication from the cavity into the tympanum, a passage passing upwards into it divided below into two by a septum of bone, one opening towards the mastoid process, the other more internally. The roof of the tympanum was dark and infiltrated, and its cavity contained dark thickened and softened membrane, and masses of firm pus-like matter; membrana tympani destroyed to the extent of about three lines by one and a-half below the malleus, forming a crescentic opening. The malleus was perfect. Stapes scarcely movable from its vestibular aspect. Tensor tympani had no muscular fibres, but exhibited clear fibroid degeneration. The vestibular sacculi were rather dark in colour, and when removed found to be thick and pulpy. Beneath the microscope they showed no pus cells. Compared with the membranes of the opposite side, this is of an opaque, dark and granular appearance exhibiting all over many cells (the vestibular epithelium), but seeming enlarged as if swollen or soft, here and there nucleated, and in some cases granular. Some of them were no doubt blood-discs. There were many nerves traversing the mass. These are mostly enlarged, headed, and granular, as if soft and swollen, a few fibres remain small; several large blood-vessels ramify throughout.

The bone on each side showed a peculiarity of form about the meatus internus which was unusually large and spiral in shape. This was most marked on the right side, and on this there ran from the meatus to the apex of the bone, a thin and sharp curved ridge, a great exaggeration of the natural crest of the bone.

The *portio dura* seemed loosened in its course through the bone. It was drawn out from the meatus internus on to the anterior surface of the bone in the act of removing the dura mater, *i.e.*, almost all of it, and the remainder readily came on traction. It could also be drawn slightly at its exit. It seemed healthy throughout, even at its exit, though here it lay close to, though not involved among, the diseased soft parts.

The internal carotid artery had its coats thickened as it passed through the diseased parts, but was otherwise healthy.

The jugular vein in this situation had also thickened coats, and was moreover filled with a firm adherent mass, not containing pus, nor any softened substance, so far as could be judged.

The left ear appeared moderately healthy in all respects.

### METROPOLITAN FREE HOSPITAL.

#### Cases under the care of Dr. C. R. DRYSDALE.

#### WASTING PALSY OF THE RECTUS FEMORIS, &c., FROM A BLOW.

NOVEMBER 30th, 1866.—William Mullens, 25, received a blow on his left thigh in front, two years ago, from a piece of iron under a steam hammer. Since that date he has suffered from pains of the thigh. He now is unable to walk, or go on with his work as a pattern-maker. When the patient is seated there is seen to be complete wasting of the triceps extensor of the thigh, and when the thigh is raised by the psoas and iliacus muscles, the shape of the

femur is clearly marked through the integuments and wasted muscles. All the other muscles of the thigh are healthy; there is a difference of two inches in the girth of the two thighs at one foot below the head of the femur. The patient in other respects healthy and muscular.

#### CARCINOMA OF THE SIGMOID FLEXURE OF COLON.

Robert C., 52, seaman; seen 4th January, 1867. Patient has suffered from profuse diarrhoea for three months past. Was formerly for some time in the East Indies. He has no straining or tenesmus, nor any blood in the stools. The stools, which he brought for inspection, were quite fluid, slightly coloured, and resembled rhubarb and magnesia mixture. Of these stools he has had as many as thirty a day, and he has not passed a solid motion for three months. Does not vomit, and is not emaciated, although thin; used to weigh 11st. 10½lbs., but now weighs only 10st. 7lbs. The finger passed into the rectum does not detect any stricture, nor does the rectum bougie passed in a little further. On examination through the parietes of the abdomen there is a feeling as if there was an inelastic substance in the left iliac fossa. Dr. Drysdale said he thought that this was a case of malignant disease of the colon in the region of the sigmoid flexure.

## Foreign Medical Literature.

### TWO CASES OF ABSCESS IN THE ANTERIOR ABDOMINAL WALL, IN CONSEQUENCE OF THE PRESENCE OF A FOREIGN BODY WHICH HAD BEEN SWALLOWED, AND WHICH PERFORATED THE INTESTINAL CANAL.

Communicated by Professors SANTESSON and KEY.

Translated from the *Hygien* for June, 1866.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

(Continued from page 78.)

IN addition to the changes in the ileum already described in the loop attached to the abdominal wall, three smaller dark blue spots, about 6mm. in length, and situated close to one another, are found in the jejunum, three feet from the duodenum. The uppermost of these is completely healed, with a loss of substance of mucous membrane, of the extent of a pin's head, in the centre. In the two inferior spots is found a similar loss of substance in the middle, and the mucous membrane is at the same time undermined throughout the whole extent of the spots. From one, moreover, a fine canal passes to an abscess of the size of a pea, in the attachment of the mesentery, filled with an ashy mass, similar to that in the hepatic flexure. Below these spots the mucous membrane in the jejunum is somewhat thickened and softened, of a reddish grey colour, with superficial diphtheritic exudation on the valvulae conniventes. The change gradually diminishes in the ileum, and ceases somewhat below the attached loop of intestine, the mucous membrane of the ileum exhibiting in its lower half only a slight swelling of the solitary glands, and in spots a somewhat greater injection than usual. In the uppermost part of the jejunum the mucous membrane presents no remarkable change.

The mucous membrane of the stomach has a perfectly healthy appearance, nowhere presenting any trace of the passage of the pin. In the oesophagus, on the contrary, there is found, about its middle, a longitudinal rent in the mucous membrane about two centimètres ('787416") in length. In the middle of this is seen a small cicatrix-like

contraction. In the two extremities of the rent, on the other hand, the extremely sharp and even edges of the mucous membrane are removed from each other scarcely a millimètre, but are everywhere perfectly attached to the fundus. In addition to the above-described changes in the intestinal canal and abdomen, important processes are met with around the spleen, in the vena portæ and liver.

Over the spleen lay the transverse colon drawn up and firmly adherent throughout a great extent to the diaphragm. In connection with this the spleen too was also attached by its edges and a great part of its upper surface, by means of firm membranes, to the diaphragm. On detaching these membranes a large diffuse cavity is found, partially filled with pus, between the spleen and the diaphragm. The diaphragm is here, through an extent of  $8\frac{1}{2}$  centimètres (about  $3\frac{1}{2}$ " in diameter, completely perforated, the perforation presenting lumpy, softened, reddish grey edges, and the hole is so bounded superiorly in great part by the inferior surface of the lower lobe of the left lung, which in its periphery is everywhere adherent to the diaphragm, that the purulent collection above the spleen is diffused through the pleural cavity itself. But posteriorly under the diaphragm and through its crura the pouch of pus communicates around the spleen with the purulent passages already described, which, after having passed under the edges of the tenth and eleventh ribs, open into the subcutaneous abscess given exit to by incision in the lumbar region of the ileum.

The capsule of the spleen is on its upper surface, looking towards the purulent collection, greatly thickened, opaque, discoloured, and in one place destroyed throughout the extent of a two-farthing piece. From this point an abscess of the size of a pigeon's-egg is continued into the substance of the spleen, which partly contained a turbid, purulent fluid, resembling that about the spleen, partly consisted of a cheesy, greyish yellow, tolerably firm mass, still adherent to the rest of the substance of the spleen. The spleen is, moreover, rather enlarged, tolerably firm, of a dark reddish grey colour, with slightly prominent Malpighian bodies, but a coarse trabecular system. A large venous branch, proceeding from the apex of the abscess above described, was filled with a thick, puriform, embolic mass, which extended into the splenic vein. A couple of other venous branches also in the spleen were filled with partly firmer, partly half broken up emboli, which in the cavity were connected with the first mentioned thrombus. The splenic vein is at its origin rather highly dilated with thickened walls. The above described emboli entering it are continued at first merely on one side into a thin, ashy layer, adherent to the wall, but at the distance of some centimètres from the hilus the vein becomes almost completely filled with an embolus, which continues as far as the trunk of the vena portæ. It is in general adherent to the venous wall, but on the under side is free from it, leaving a narrow passage open for the stream of blood, which comes from the non-obstructed venous branches in the spleen. In this passage lay, as further proof that a current of blood had passed along the thrombus, a loose, fresh filamentous coagulum. The embolus itself is in the central parts in a half broken up state, of an ashy, opaque, greyish yellow; in its periphery it is, on the contrary, firmer, and of a reddish grey colour. At the inoculation of the mesenteric veins it terminates for the greater part in a rounded off extremity, which projects into the vena portæ, which, moreover, in its whole trunk and in the commencement of most of its branches is invested with a thin layer of a perfectly pus-like, rather viscid mass, adherent to the walls. In places the walls of the vena portæ are indeed preserved, but through a very great extent, and this is even the case in the commencement of some branches to the right lobe, the venous walls are completely destroyed, so that the boundary is formed of surrounding connective tissue, covered with an ashy, pus-like substance, like that of the remaining venous walls. Where the complete destruction of the venous walls ceases, these are, through a longer or shorter space, loose, softened, and as it were infiltrated with pus. Several of the venous branches in the liver so altered in the commencement, have subsequently their calibre perfectly free throughout their

whole course, with walls of normal appearance, and around their ramification too no greater changes are visible. Otherwise, in the somewhat destroyed liver, both superficially and in its substance, foci of sizes varying from that of a hen's to that of a pigeon's egg, in which a great number of small abscesses, from the side of a hempseed to that of a pea, lie scattered, are met with. They are in general sharply defined, and separated from one another by a whitish-grey and tolerably firm sclerotic tissue. The venous branches leading to these foci, which are in general rather thickened, are in many places filled with a greyish white, ashy mass, like that in the trunk of the vena portæ. Here and there a mud-like substance can be expressed from the finer venous branches, even in places where no abscesses exist. Otherwise the hepatic substance is tolerably firm, of a reddish grey colour, with some tendency to yellow; in parts the acini are surrounded with intensely red, somewhat depressed rings, in their centres strongly inclining to yellow.

In the mesenteric veins, which were dissected up as far as possible, no traces of emboli were anywhere found. The kidneys were pale and healthy.

On opening the chest the lungs collapsed tolerably perfectly. The left lies with its lower margin drawn up on the diaphragm pushed up to the level of the fifth rib, and is about the lower surface everywhere adherent at the periphery to the diaphragm. In the pleural sac a couple of ounces of clear serous fluid were found.

On separating the lung from the diaphragm an encysted abscess was found, as before described, communicating with the abscess around the spleen. The pleura was to a corresponding extent very much softened, of an opaque greyish red, with some slight losses of substance, which were continued into the pulmonary substance, and were there bounded by an eroded, opaque, grey, thin, and tense layer of pulmonary tissue. The lower lobe of the lung is through an extent of one and a-half centimètres next its under surface atelectic, yielding on pressure a small quantity of non-aerated fluid. Moreover, the lung in the posterior parts is rather œdematous, but otherwise its parenchyma is healthy. The bronchi contain a tolerably large quantity of catarrhal secretion. In the infero-posterior margin of the right lung is found a small hard, reddish grey focus of hepatisation of the size of a pea. Otherwise the parenchyma in this lung also is healthy. The bronchi contain here also a tolerably copious secretion. The heart is rather smaller than usual, the subpericardial fat is changed into a loose, gelatinous substance. The muscular structure is pale and firm. There is nothing else to remark.

If we now endeavour to put together the results of the post-mortem examination, and to compare them with the history of the case communicated by Hr. Santesson, it will first of all appear evident that the pin found in the abscess in the abdominal wall was the cause both of the changes immediately about it, and also of the other morbid processes. Neither can there be any doubt that the pin reached its present situation by perforating the intestine, after having been swallowed. Had it penetrated from without the woman would certainly have been aware of it, little sensible as she seems to have been. Moreover, the bowel within the place where the pin lay bears evidence of its passage. The pin seems here, even after it was brought into a transverse direction, to have several times penetrated the intestine, but to have again got free, before it finally perforated the bowel. The one dark spot reproduces so exactly its form, that it seems impossible that it could have occurred in any other manner than by the pin penetrating under the mucous membrane into the submucous tissue. Above the place where the pin perforated the intestine but little trace was found in the digestive canal of its wandering. The slit described with cicatrization in the œsophagus appears, however, to be scarcely explicable in any other way than that it was caused by the pin. That it was produced by some sharp substance which had been swallowed is certain. The dark-blue spots found in the jejunum cannot with any certainty be referred to lesions of the pin, for they may easily have occurred from the intense inflamma-

tion of the peritoneum, which caused, among other things, the abscesses in the attachment of the mesentery, propagating itself on the intestinal wall with such violence as to give rise also to submucous abscesses, causing secondary losses of substance in the mucous membrane. In this manner, no doubt, did the similar changes occur in scattered parts of the colon and rectum with the perforations found there.\*

That the pin in its passage caused an intense local peritonitis, with adhesion of the intestine, follows from the history of the case compared with the results of the post-mortem examination; but these latter show likewise that general peritonitis set in at the same time, which subsequently underwent occasional exacerbations, producing the extensive lesions in the true pelvis, and here and there abscesses in the mesenteric attachment, and phlegmonous inflammations in the intestines, with the changes described around and in the spleen. As to the changes in the true pelvis, it is most remarkable that during life they gave rise to such slight symptoms. It is, indeed, probable that for the most part they set in during the last six weeks after the exacerbation, in the middle of January, as well as that the perforation of the rectum was the cause of the severe diarrhoea, which began thirteen days before death, and which was afterwards kept up both by the follicular colitis and by the enteritis.

The intense purulent perisplenitis with perforation of the diaphragm, formation of abscess in the spleen, embolus in the splenic vein and suppurative pylephlebitis, is of special interest. As to the origin of the perisplenitis it would appear that it ought to be referred tolerably far back, and the process must here, as well as in the true pelvis, be considered as a local increase of the general peritonitis produced by the irritation of the pin. Even from November and the beginning of December, the history of the case records symptoms which must be attributed to inflammation around the spleen, but it was not until January that this became extremely aggravated, producing, as was assumed, a considerable purulent encysted effusion, which pushed the diaphragm upwards, and compressed the lung, until by gravitation of the pus backwards, and incision in the lumbar region, the matter in part gained an exit. Contemporaneously with this exacerbation, if not before it, the splenic abscess set in, causing thrombosis of the veins of the spleen; and, secondarily, through emboli and continued thrombosis, the suppurative pylephlebitis, symptoms of which seem to have occurred shortly after the exacerbation in the middle of January, although they were so obscure that this affection, as so often is the case, could not with certainty be diagnosed. We have here, therefore, a fresh case, where a suppurative pylephlebitis was occasioned by an abscess in the spleen. Some years ago I communicated such a case, and to this time, so far as I know, in addition to these two cases, only four similar ones are known, which I quoted in my former paper. (*Hygiea*, 1862, p. 257.)†

But in the present case the pylephlebitis possesses a very special interest, for it shows that, in a breaking up thrombosis with suppuration around it, not merely the detritus mass of the thrombi, but actually genuine pus, may be added to the blood, a circumstance which does not tally with the theories commonly current. It is, in fact, said, that when suppuration sets in, in consequence of a breaking up thrombus in a vessel, the products of suppuration remain, after the destruction of the vascular walls, "in general" hindered from being directly added to the blood, by continued obstructing thrombi which confine them. (Virchow, Weber, &c.)

An indirect proof that the pus perforating a vascular wall in thrombosis may enter the circulation of the blood is thus indeed supplied, but as it appears to me not very decisively. The case now before us is particularly favourable to this view. Thus, in the trunk of the vena portæ

the inner membranes were partially destroyed, and the boundary was composed in part of adventitious portions of the inflammatorily altered connective tissue in the immediate vicinity. On microscopic examination, these tissues were now seen to be highly infiltrated with pus cells, and in towards the calibre they were in a state of complete purulent change, so that no well-defined demarcation was found between them and the pus-like ashy mass, consisting almost exclusively of pus cells which covered the walls. The boundary of the cavity traversed by the current of blood was therefore here a connective tissue, suppurating or in a state of purulent disintegration; and as the vast majority of the branches of the vena portæ were completely permeable, the products of suppuration, or the pus, must also have been conveyed directly into the mass of the blood. The microscopic examination of the vascular walls themselves where these were in a state of disintegration, in the neighbourhood of places where they were already completely destroyed, was especially interesting. A large venous branch to the right lobe, in the commencement of which all the membranes were destroyed, was examined with particular accuracy. At the very limit of the destruction the inner coat projected more than the other membranes, and terminated in a ragged margin, floating when water was poured on. Fine transverse sections, which are preserved in the museum here, exhibited through all the membranes, strong infiltration with pus cells, which at a greater distance from the suppuration became fewer. Even the innermost membrane was altered in the same manner, particularly close to its ragged margin, and there was no difficulty in convincing one's self that the cell-proliferation proceeded, as in endarteritis, from the normal elements in the membrane itself. Finally, that the inner coat was destroyed by an actual purulent disintegration was therefore evident. In the venous branch examined, not a trace of thrombi or emboli was found in its whole course from the spot where the suppuration took place, and where its dilated cavity, as in the portal trunk, was covered with a puriform mass, nor in its seat of ramification and in its circulation could the blood through it convey pus. I hope soon to be in a position to treat somewhat more fully of the latter subject so interesting in itself, which has here formed only an episode, though a fearful episode, in "l'histoire d'une épingle."

In connection with the foregoing, a similar case, which, however, terminated in recovery, may here be mentioned.

A housekeeper from the country, aged 63, had in the month of June, 1864, come to Stockholm to seek relief for an abdominal affection, from which she had suffered for rather more than six months. The symptoms at first resembled most closely those of cardialgia; tenderness and pain in the epigastrium, in connection with lancinating pains both there and in the corresponding part of the back. On exercising or working she was most troubled with these symptoms, especially if the stomach were empty, although they also occurred readily after taking food. A feeling of tension and fullness beneath the breast, with extreme tenderness on pressure in the epigastrium, came on after some time, accompanied, although more rarely, with water-brash, nausea, and loathing. Finally, an extremely tender swelling appeared in the vicinity of the ensiform process, gradually increasing in extent, scarcely allowing her to dress herself, as her stays and hoops constantly pressed upon the painful part. This was the immediate cause of her determination to seek relief in the capital. As the physician to whom she first applied, on examination, found a tumour in the pyloric region, of considerable elasticity, extremely painful on pressure, and, as it seemed rather diminishing in size thereupon, he referred the patient to me (Santesson), thinking there might possibly be a rupture, or something else "surgical" in the case. I visited her at her house, and then found that the swelling must in great part contain fluid, even though concealed by that, something else might possibly be in the back ground. The tumour, which was oval, extended from the lower extremity of the sternum, in the direction of the linea alba, for somewhat more than four

\* According to a chemical examination made by Prof. Stenberg, the crust deposited on the pin was found to contain lime, oxide of zinc, and oxide of copper, combined partly with phosphoric and partly with carbonic acid.

† The reader who may wish to refer to the paper above alluded to, will find it translated in *extenso* in THE MEDICAL PRESS, January 7 and 14, 1863, pp. 4 and 28.

inches, towards the umbilicus, its greatest breadth was nearly three inches. Over the margin of the ribs, particularly on the left side, there was great tenderness on pressure. Otherwise the part was in good condition and looked healthy, nor did the patient exhibit any disease in any other organ. I introduced an explorative trocar in the most prominent and fluctuating part of the tumour, which, however, gave exit to nothing; but after the canula was removed and blown through, it was seen that it contained some drops of viscid, yellow pus, too thick to admit of its passing through the small tube. It was now evident that we had to deal with an abscess. Its gradual development, in connection with other characters, and the great tenderness over the margin of the ribs, led to the suspicion that the formation of pus depended on necrosis in some adjacent cartilage or rib. I then advised the patient to seek admission into the hospital, where she was inscribed on the 23rd June, 1864.

The tumour was now opened with an incision a couple of inches in length in the middle line, whereupon between four and five ounces of laudable pus were discharged. The cavity of the abscess was not continued to any distance, nor could any rupture or other connection with the abdominal cavity be discovered. The walls were smooth, for the most part lined with a "concrete pus," extending upwards and to the left side in the connective tissue without the peritoneum behind the ensiform process and the margin of the ribs. No denuded bone or cartilage was anywhere met with. Moist, calefacient fomentations, replaced at night by poultices, constituted the whole treatment, taking care at the same time to keep the incision open, as the latter showed a great tendency to close over the purulent cavity which was not yet filled up. The secretion from this continued to a tolerably considerable amount for about three weeks after the operation. On probing the wound a little later the margin of the seventh costal cartilage on the left side was found denuded, but no portion of it was separated. In addition, the probe encountered a solid, movable body, which was impacted in a wall of the cavity, and which, after having been taken out by Acting-Assistant P. A. Enestrom, was found to be a fish bone, about an inch in length, forming part of a rib of some kind of large fish, such as a pike. The bone had evidently been long exposed to the action of the pus, for its two extremities were almost dissolved by maceration to the state of brittle, pencil-like bristles, and there can be no doubt that this foreign body, perforating the wall of the stomach, or possibly some other part of the intestinal canal near the stomach, had been the original cause of the abscess in the abdominal wall. The patient herself could not recollect any occasion on which she had observed any difficulty or pain in or after taking food. After the bone was removed the purulent secretion rapidly diminished; the cavity gradually contracted, so that on the patient's dismissal from hospital, on the 21st of the following August, it was all but healed. Later in the autumn I learned from her mistress that the cure was complete, and somewhat more than a year after I was informed that the patient continued perfectly well.

## MEDICAL GLEANINGS.

(From the British and Foreign Medico-Chirurgical Review.)

### ANATOMICAL AND PHYSIOLOGICAL INQUIRIES RESPECTING THE MOTOR NERVES OF THE UTERUS.

By Dr. THEODORE KORNER.

DR. KORNER observes that the uterus in the human subject is supplied by two sets of nerves; one, proceeding from the inferior mesenteric ganglion of the sympathetic, the other proceeding from the middle sacral nerves. These two sets unite in a plexus, the branches of which are distributed over the rectum, bladder, upper half of the vagina, and the portio vaginalis uteri. Numerous ganglia, the presence of which has been alternately admitted and rejected, are clearly visible in various parts of the uterine structure, when this has been

treated with vinegar, and a weak solution of bichromate of potash.

Dr. Korner's physiological experiments upon the above nerves were chiefly undertaken in rabbits, in which animals he found the distribution of the nerves to agree in all essential respects with that of the human subject. The chief results at which he appears to have arrived, after a course of inquiry extended over a considerable period of time, are:—

1. That electrical excitation of the branches of the sacral nerves distributed to the uterus are constantly followed by contractions of that organ.
2. That electrical excitation of the branches of the sympathetic nerve distributed upon and embracing the aorta, is also constantly followed by contraction of the uterus. On the other hand, section of these two sets of nerves renders it impossible to excite uterine contractions by electrical excitation of the spinal cord. These two sets of branches must therefore be regarded as the only motor nerves of the uterus.
3. Irritation by electricity of any portion of the spinal cord is followed by uterine contractions, providing only that the motor nerves distributed to the uterus are uninjured; and contractions are induced with greater facility in proportion as the central part of the lumbar region of the spinal cord is approximated, which is to be considered as the point best adapted for the induction of uterine contractions by electrical excitation.
4. Each of the two above-mentioned sets of nerves—the sacral spinal and the sympathetic—possess motor branches for the muscular tissue of the uterus proper to themselves, for if either of them be divided uterine contractions can still be occasioned by applying electrical excitation to the other, though in the case of the sympathetic branches the agency exerted seems to be an inhibitory or regulatory one, bringing movements already commenced to a stand-still.
5. The sacral spinal branches for the supply of the uterus leave the spinal cord in the region intermediate to the third and fourth lumbar vertebrae. The uterine branches of the sympathetic, on the other hand, leave the cord at about the level of the last dorsal vertebra, as is shown by the fact, that on section of the spinal cord above this point electrical irritation of the upper segment is no longer followed by uterine contractions.

As regards the presence of a central cerebral nucleus for the excitation of uterine contractions, Korner's experiments do not lead to the supposition that any such exists, but he found that contractions of the uterus could be induced by electrical stimulation of the medulla oblongata, cerebellum, pons varolii, corpora quadrigemina, crura cerebri, corpus callosum, optic thalamus, and corpus striatum, but that the contractions were more easily called forth in proportion as the point irritated approximated the medulla oblongata.—*Heidenhain's Studien des Physiolog. Instituts zu Breslau, 1865, p. 1.*

### ON THE INFLUENCE OF THE NERVOUS ACCESSORIES ON THE MOVEMENTS OF THE HEART.

By R. HEIDENHAIN.

HEIDENHAIN commences his paper by observing that without entering into a discussion of the whole subject of the existence or non-existence of inhibitory or regulatory nerves, he is desirous of recording a few observations, which, whilst they appear to him to militate against the exhaustion theory promulgated by Schiff, yet seems to favour the view that the pneumogastric nerves are not inhibitory, but motor nerves, so far as regards the heart. He describes the rough anatomy of the roots of the pneumogastric and spinal accessory nerves in the rabbit, and the relations of their trunks to one another. He states that the accessories in rabbits can be torn out by the roots with the greatest facility, whilst this is more difficult to accomplish in dogs, in consequence of the fibrous nature of the passage by which it leaves the skull in those animals. The accessory nerves are doubtless the special motor nerves of the larynx. The effect of their evulsion was long ago stated by Bernard to be paralysis of the larynx, in reference to its phonetic attributes only, but Heidenhain agrees with Schiff in thinking that the paralyzing influence is exerted upon the respiratory functions of the larynx as well as upon those connected with the voice. Thus one of the earlier consequences of paralysis of the larynx is, not unfrequently, death by the entrance of food into the air-passages. If the animal survives the operation for some time, it often dies from pulmonary inflammation, also occasioned by the entrance of particles of the food into the bronchi, whilst in other instances pleurisy or pericarditis supervenes.

The frequency and rhythm of the respiratory acts is unaltered

after the evulsion of the accessory nerves, nor do the movements of the stomach and alimentary canal seem to be in any way interfered with, provided that a branch to the œsophagus given off from the pneumogastric very high up, is not damaged.

Heidenhain holds that the inhibitory nerves of the heart contained in the trunk of the pneumogastrics primarily originate in the accessory nerves, since he has found that a few days after evulsion of the accessory nerves from the jugular foramen, the excitation of the pneumogastric nerve is not followed by its wonted inhibitory effect. He has observed, also, that evulsion of the accessory nerves is constantly followed by increased frequency in the beats of the heart, unless only in those cases where the rapidity of the heart's action before the operation was very considerable. The deep origin of the inhibitory nerves existing in the trunk of the spinal accessory nerve appears to be from the medulla oblongata, and not from the spinal cord. In opposition to the results obtained by Schiff, Heidenhain finds that section of the pneumogastric nerves, after previous evulsion of the spinal accessory nerves, is constantly followed by a diminution in the frequency of the beats of the heart, which he attributes to the derangement of the respiratory mechanism consequent on the former lesion. On the whole, therefore, he concludes that the inhibitory nerves of the heart contained in the vagus, originally proceed from the nervus accessorius Willisii, for, on the one hand, the stoppage of the heart's action, induced by excitation of the pneumogastric, is dependent on the integrity of the accessory fibres, and, on the other hand, evulsion of the accessorius is followed by increased frequency of the pulse, and if the pneumogastrics are afterwards divided, the frequency of the heart's beats may be diminished in consequence of embarrassment of the respiratory mechanism. If, under normal circumstances, the vagi of an animal are divided, this lesion operates in two opposite directions upon the rapidity of the heart's action; for the division of the accessory fibres contained in the pneumogastric trunk occasions an acceleration, whilst the division of the proper vagal fibres induces a retardation of the cardiac beats; and usually, as is well-known, the former influence preponderates—the pulse rising in frequency.—*Heidenhain's Studien des Physiolog. Instituts zu Breslau, 1865, p. 109.*

#### CRITICAL AND EXPERIMENTAL INVESTIGATIONS ON THE THEORY OF THE INHIBITORY NERVES.

By Dr. E. F. M. PFLUGER.

PFLUGER commences his paper by observing, that all the facts which Schiff and Moleschott believe they have established against Pfluger's doctrine of the inhibitory influence of the vagus upon the heart are illusory. Schiff, it is well-known, considers that by extremely feeble stimulation of the vagus the frequency of the beats of the heart may be increased, but that if the exciting electrical force be increased, even to a very moderate amount, the vagus becomes exhausted, and is no longer capable of transmitting the normal motor energy to the heart. Schiff acknowledges the variation of frequency under gentle stimulation to be very slight, indeed scarcely more than occurs under ordinary circumstances, without stimulation. Now, in reply to these statements, Pfluger first adduces a series of experiments, in which he shows that with extremely feeble currents applied to the vagus of the frog either no variation takes place in the heart's frequency or the number of beats is absolutely diminished.

Again, Schiff maintains that—1. It is the accessorius whose stimulation really induces the stoppage of the heart's action when a current of moderate force is applied to the vagus. 2. That paralysis of the accessorius causes no increase in the number of the beats of the heart. But that—3. The division of the vagus in the neck occasions the increased frequency of the pulse, as has been so often observed. Pfluger remarks on this, that the very recent experiments by Heidenhain (above recorded) have shown that the tearing out of the accessorius occasions an increase in the frequency of the pulse, whilst, according to Schiff, paralysis of the accessorius has no influence on the heart. Heidenhain has also shown that after tearing out the accessorius, at which time irritation of the trunk of the vagus occasions no increase of the heart's beats, section of the vagi does not, as Schiff contends, produce an acceleration, but a diminution in the number of the beats. Heidenhain explains this by supposing that an indirect influence is exerted upon the heart through the deficient play of the lungs, but Pfluger thinks it reasonable to suppose that when the accessorius was

torn out the vagus also suffered. He then enters into a critical examination of Moleschott's experiments, in which electrical, chemical, and mechanical stimuli were applied, and points out various sources of error.

Moleschott's conclusions from his experiments were—

“1. That weak excitation of the sympathetic causes increased frequency of the pulse. 2. That this effect is not of a reflex character. 3. That strong electrical stimulation applied to the sympathetic can bring the heart to rest.”

Of these propositions Pfluger considers the first two to be insufficiently proved, and the last to be absolutely erroneous. The conclusions at which Pfluger has arrived after repeating and variously modifying his former experiments, are, that the very first effect which weak currents of electricity transmitted through the vagus nerves effect, is a prolongation of the diastole of the heart, and that, under no circumstances, is the rapidity of the heart's action primarily increased by such stimulation, whether the electrical stimulus be strong or weak. He has also investigated again the action of the splanchnic nerves, when irritated, on the peristaltic movements of the intestines, and does not hesitate to pronounce as erroneous the statement of Schiff that it increases their rapidity and energy. He regards them as being essentially the motor nerves of the arteries distributed to the intestines.—*Untersuchungen aus dem Physiolog. Institut zu Bonn, herausgegeben von Dr. Pfluger.*

### Reviews.

#### ON DISEASES OF THE RESPIRATORY PASSAGES AND LUNGS. By WALTER GOODYER BARKER, M.D. London: John Churchill and Sons.

THE chief object of this treatise is to bring into prominent relief the effects of atmospheric vicissitudes in the production of disease. The author seems to think that the subject has not yet received so much attention as it deserves, and having made a special study of *medico-meteorology* for upwards of fifteen years, is entitled to be heard.

For this reason we could almost wish he had resisted the temptation of describing the symptoms, course, and treatment of the diseases of the air passages, and confined himself to the development of his ideas on their causes, not that we complain of the manner in which the descriptions are given, but that they almost necessarily distract the reader's mind from the proper theme of the work, and so tend to throw into the shade the points which the author is most anxious to make prominent. It is, however, a temptation which perhaps few writers would be able to resist. Our notice will be mostly confined to Dr. Barker's propositions in reference to *causes*, which furnish him with the following classification of diseases of the respiratory organs:—

- 1.—Those which owe their origin to the immediate contact of the atmosphere upon the diseased part. Under this head he treats of coryza, catarrh, laryngitis, tracheitis, bronchitis, and pneumonia.
- 2.—That produced by the application of cold to the surface of the chest—viz., pleurisy.
- 3.—Epidemics. These are, according to our author, influenza, hooping cough, and measles.
- 4.—That which arises from constitutional causes, hereditary or acquired—viz., phthisis.

It is, however, admitted that this division is somewhat arbitrary, inasmuch as we can scarcely maintain that any one of these diseases is constantly produced by either cause singly.

The whole book is eminently practical, and many valuable remarks are scattered throughout, showing the author to be an observant physician; so that, in spite of the one defect we have named, and some rather involved sentences which occasionally obscure the meaning, but may easily be removed in a future edition, we have found it very readable. It might be anticipated that an author who looked upon diseases of the respiratory passages from this point of view would have much to say of weather and climate, and such is in fact the case. Dr. Barker has long been physician to the Worthing Infirmary, and has a good deal to say in favour of the winter climate of the whole South Coast of England, and particularly of that of Worthing. In reference to this, he alludes to the influence of the Gulf-stream impinging on our South and South-West coast, as pointed out by Maury in his *Physical Geography of the Sea*. No one can doubt that to this is, to some extent, due the climate of our home winter resorts, which Dr. Barker contrasts

rather favourably with those of the Mediterranean. Having suffered many years from preternatural sensibility of his own air-passages and found relief at Worthing, and his own father, in spite of bronchial disease and tendency to bronchitis, having survived to the age of eighty-one in comparative comfort, he certainly has a right to speak well of the town.

Its climate is doubtless much less stimulant than that of a large number of fashionable foreign resorts, and deserves attention in a class of cases in which we have reason to dread too directly stimulating an effect. One or two of the cases in which its influence is described were undoubtedly striking. We should, nevertheless, be glad to obtain a more exact definition of the cases in which it is most appropriate. In asthma we have little faith in our own coast, and are almost inclined to subscribe to the doctrine that is gaining ground, that London is about the best winter home for asthmatics. The sad failures of all climates in confirmed phthisis are very discouraging. Where a very powerful stimulant is needed we look to the Mediterranean, or to a still greater distance. For direct sedative influence we should turn to the Pyrennees. But for a *medium*, away from our own few places, where can we turn except to Rome—unless, indeed, San Remo on the Riviera shall be able to establish the claim that has been put forth on its behalf?

Then, again, there are a large number of cases in which change of climate may be desirable, but in which it is almost dangerous to attempt it, lest we do too much. We should be glad to hear Dr. Barker's experience of the effect of the climate of Worthing on those diseased states following epidemics, and especially in the remains of consolidated lungs coming on in the course of measles. If he could show that Worthing would aid the repair of such a condition he would confer a real benefit on a large number of sufferers, and secure for the town a prosperity equal to that of any winter resort at home or abroad. Space forbids further discussion of this interesting topic, and we have only to add that the same inexorable fact prevents our entering upon several others we had intended to mention in our notice of this interesting little volume.

**A PRACTICAL TREATISE ON APOPLEXY (CEREBRAL HÆMORRHAGE):** its Pathology, Diagnosis, Therapeutics, and Prophylaxis; with an Essay on (so-called) Nervous Apoplexy, on Congestion of the Brain and Serous Effusion. By WILLIAM BOYD MUSHET, M.B.Lond., M.R.C.P.L. Pp. 194. London: Churchill and Sons. 1866.

UNDER the general name of Apoplexy there is no doubt that many affections of very different pathological origin have been, and still are, erroneously comprehended. The object of Dr. Mushet in the work now before us is to extricate it as a substantive disease from an assemblage of symptoms, or, in other words, from the multiform phases of coma. In fact, he restricts the term apoplexy to those cases where there is hæmorrhage within the cranial cavity, and he endeavours to point out the symptoms indicating this lesion, and the treatment to be adopted in obviating its consequences. Excluding, therefore, such cases as uræmia, and narcotic poisoning and drunkenness, and regarding the disease as due to an extravasation of blood, Dr. Mushet discusses in a very able and intelligent manner the question as to the reasons why apoplectic effusions should occur, and the conditions necessary for bringing about such a result. The two views generally entertained as to the cause of apoplexy are—first, that it is caused by hypertrophy of the heart; and secondly, that it is due to degenerative disease of the cerebral arteries, the former opinion being advocated by Dr. Burrows, and the latter being generally adopted by modern pathologists. But while Dr. Mushet's researches appear to confirm the impression that some enlargement of the heart is a very constant accompaniment of apoplectic seizures, he by no means believes that these two circumstances are necessarily to be regarded as cause and effect, because another factor is indispensable to the result—namely, the degeneration of the arteries. He very justly observes, that out of the numerous cases of enlarged heart, to be found among the applicants for medical relief at hospitals and dispensaries, only comparatively a few are seized with apoplexy, while on the other hand he maintains that the natural degeneration of the arterial coats is not followed by apoplexy, unless there be also an enlargement of the cardiac walls. It is in the latter assumption that the chief novelty of Dr. Mushet's opinions consists; and he has brought forward a number of cases in which the weight of the heart was accurately taken, in proof of his position. It may be mentioned that a great portion of

Dr. Mushet's experience was drawn from the practice of the Marylebone Infirmary, of which he was for some years the resident medical officer, and where there exists a wide field for pathological research. The treatment of apoplexy is described at considerable length, and the arguments for and against the use of the lancet are very fairly adduced, and probably the general opinion of the profession will coincide with that of Dr. Mushet, who thinks bleeding justifiable in robust persons, when the symptoms are comatose more than syncopal, the lethargy profound, and paralysis present. We consider this treatise to be at once philosophical and practical, and worthy of the attention of the profession.

**ELEMENTS OF CHEMISTRY: THEORETICAL AND PRACTICAL.** By WILLIAM ALLEN MILLER, M.D., LL.D., Professor of Chemistry in King's College, London. Third Edition, with additions. Part III. Organic Chemistry. Pp. 1014. London: Longmans. 1867.

THIS bulky and most comprehensive volume, which is complete in itself, and may be obtained separately from its two predecessors, is a most able and learned summary of the present state of Organic Chemistry. What this branch of chemical science was thirty years ago is well-remembered by many of the present generation; what it may become thirty years hence it is impossible to conjecture, so numerous are the ramifications it presents, so extensive are its connections with the study of animal and vegetable life, and with the operations of commerce and of art. Every day new and hitherto unsuspected analogies are discovered, binding together some apparently disconnected facts brought to light by separate and laborious observers; every day some new discovery in the practical applications of chemistry adds to the comfort, the welfare, or the enjoyment of mankind. In the department of organic chemistry, in particular, the operations of life, in its ever varying conditions, are traced in all their subtle changes, and the products of organization are found to be amenable to the same molecular transformations as those which are traced in the brute matter constituting the earth, the waters, and the air. Whether the present very ingenious theories of organic chemistry will hold their ground, or whether they will be succeeded by others equally ingenious but, perhaps, more simple, time alone will determine; but "sufficient unto the day is the evil thereof," and the student of 1867 must master, as best he may, the complicated formulæ now presented to his acceptance, although he may regard the existing aspect of chemical philosophy like the shifting colours and angles of a kaleidoscope, which a new development of facts or theories may presently arrange in some new and fantastic combinations.

The most important changes made in the present edition of Dr. Miller's now well-known "Elements of Chemistry" consist, as the author tells us in the preface, in the adoption of the new form of notation, employed originally by M. Gerhardt, and now adopted by many distinguished chemists both in this country and on the Continent. It has lately been prominently advocated by Professor Williamson, of University College, London, and it is adopted at the University of Cambridge, and the publication of Dr. Miller's new edition will probably render it still more widely known. The columns of a medical journal are not the appropriate locality for a discussion of the merits of the new as compared with the old notation, and we, therefore, abstain from making any commentary upon the undoubted difficulties, both in theory and in practice, which will necessarily attend the attempt at a general introduction of the new system; but we may state with perfect truth that those who wish to study the whole subject under the novel phase which it presents in consequence of the recent changes in nomenclature and notation, will find ample information on every point in Dr. Miller's pages. They form, indeed, the best text-book now existing on the whole subject of chemistry, gigantic as the proportions of that science have now become.

**THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.** Nottingham Meeting, August, 1866. Report of the Papers, Discussions, and General Proceedings. Edited by Wm. TINDAL ROBERTSON, Esq., M.D. Nottingham: Thomas Forman. 8vo. 1866.

It would be impossible for us to give anything like an abstract of this volume, which has been ably edited by Dr. Robertson, and which contains much that is interesting and important to our profession. The attempt to single out any papers for special remark would prove of no use, for in truth there is little

in the volume that is not of interest to the special class for which it is intended. The sections on Chemical Science and on Biology will prove worth reading to many of the subscribers to this journal.

**A PRACTICAL TREATISE ON RUPTURE: its Causes, Management, and Cure, and the various Mechanical Contrivances Employed for its Relief.** By T. P. SALT. [2nd Edition.] 8vo. Churchill, London. 1865.

This is a second edition of Mr. Salt's well-known treatise on rupture, and is designed to explain the various trusses made by him in Birmingham. In THE MEDICAL PRESS for 14th June, 1865, we expressed our favourable opinion of some of his trusses then exposed in the Dublin International Exhibition, and we now commend his book to the profession. Mr. Salt is a mechanic, not a surgeon; he explains what rupture is, and, omitting how it should be treated, he explains the mechanism and use of various kinds of trusses employed for its cure or relief.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 30, 1867.

### THE DREADNOUGHT AND GREENWICH HOSPITALS.

THE familiar spectacle witnessed by all travellers on the river Thames of the stately ship now used as a floating hospital, cannot have failed to impress the public mind with the sense of a necessity of some such institution for the reception of mariners disabled from pursuing their calling from accident or disease, and for whom no other refuge of a similar kind is at present available, for it must be recollected that sailors of all nations and coming from any ports are at once received at all hours of the day or night, and the benefits conferred on thousands of our ever-changing maritime population are thus inestimable. Not only do those who have suffered from sudden illness or the effects of accidents receive prompt and efficient succour, but the victims of long-standing disease, or the martyrs from the endemic fevers of hot climates, find in this home a welcome shelter from the troubles and inconveniences of a long sea-voyage, and a careful administration of the medicines and diet suggested by the sagacity of modern medical science.

It is universally admitted that the managers of the Seamen's Hospital Society have honestly and conscientiously administered the funds entrusted to their care, and that the general arrangements are not only free from censure but are the subjects of public admiration. It is, therefore, quite unnecessary to defend the institution, as no charges have been brought against it, and its utility is unquestionable; but it is the more extraordinary that the Government of the country has for a considerable period withdrawn from the Society the assistance which it once rendered, with the exception of allowing an old ship of war to serve the purpose of the hospital.

It appears that the *Dreadnought* Hospital was incorporated, in 1833, by an Act of Parliament, and in the first years of its existence, the nation, through Parliament, not only provided the ship, but contributed also pretty largely to its support, the yearly allowance for the first ten years being about £450 a-year, and for the next ten years upwards of £1700 a-year; but since 1854 Parliament has withheld any pecuniary aid, and the consequence, as we understand, is, that the Society has had to encounter an average yearly deficiency of about £1520.

But, independently of mere pecuniary considerations, it is now evident that the ship is no longer suitable for the purposes to which it is applied, and this objection attaches not only to the present ship, which, as to its material fabric, is in a very fair condition, but to any ship whatever. A ship is indeed a very useful structure for the purposes of an hospital when no other can be obtained, and under certain circumstances, as of war or pestilence, it is better than a stationary building, because the patients can be readily moved from one spot to another. But in time of peace, and under the present conditions of our Royal and Mercantile Marine, the reception of sick and wounded patients in a ship is on many accounts objectionable; there is, for instance, want of height between the decks, want of light for the performance of operations, too much noise to be consistent with the repose of the sick, too little ventilation for some diseases, and too much for others; and what is worse than all, the timbers of a ship, notwithstanding all the precautions of science and practical skill, absorb and retain miasmatic emanations, and thus serve to perpetuate some of the worst and most fatal forms of disease.

Now, if these inconveniences were unavoidable and irremediable, it would be useless to complain, and the balance must be struck between the advantages and the disadvantages of the institution as it stands; but it so happens that a most favourable opportunity has sprung up for removing it on shore, and for receiving the patients in a spacious structure which is now devoted to no useful purpose whatever. Greenwich Hospital, the noble fabric nearly opposite to which the *Dreadnought* Hospital Ship is moored, is now untenanted, and the natural inquiry is made, why the Government does not gracefully appropriate its empty wards for the reception of the sick mariners who are now treated on board the ship. But all the Government has consented to do is to offer to sell to the Seamen's Hospital Society, at a considerable profit, a piece of land adjoining Greenwich Hospital, and on this site the Society would be obliged to build, at an enormous outlay, a new hospital, and thus to swallow up in its erection, nearly the whole sum, from the interest of which the present expenses of the establishment are defrayed.

The objections made to the appropriation of a

part of Greenwich Hospital to the purposes of the Seamen's Hospital are of a very shallow nature, although they may perhaps be satisfactory to the official mind. The great stumbling-block is, of course, that Greenwich Hospital was intended for seamen of the Royal Navy, but then the notorious fact presents itself that the persons who were the chief parties concerned—namely, the Greenwich pensioners, as they were called, have almost unanimously declined the boon, and have left the hospital, preferring to receive the pension without the residence. They are never likely to return, and the space is therefore available for any public and useful purpose to which it may be adapted, and none certainly appears more suitable than the treatment of sick sailors, whether belonging to the Royal Navy or the Mercantile Marine. It is also urged, and with justice, that the dimensions of Greenwich Hospital are so great that only a portion of the space need be occupied by the Seamen's Hospital, and sufficient accommodation might be left to meet any future emergency.

As a mere matter, too, of pounds, shillings, and pence, it appears that the Mercantile Marine has an actual claim upon the Government, for the wages and effects of deceased seamen, to which no claim is established on the part of the relatives, were formerly paid to the *Dreadnought* Hospital, but are now paid to the Board of Trade, and the latter is therefore bound to contribute towards the maintenance of sick seamen.

#### DEATH OF THE PROVOST OF TRINITY COLLEGE, DUBLIN.

THE Rev. RICHARD MACDONNELL, D.D., who had filled this important office since 1852, died at the Provost's House on the 24th inst., of acute bronchitis, at the advanced age of eighty years.

Dr. MACDONNELL was a Fellow of Trinity College for many years, and practised at the Irish Bar with considerable success. He subsequently took Holy Orders, both before and after which he filled various College offices up to the time of his appointment to the Provostship by Lord JOHN RUSSELL.

It is believed that his successor will be either the present Vice-Provost, the Rev. Dr. LLOYD, or the well-known Irish scholar and archæologist, the Rev. JAMES HENTHORN TODD, D.D., eldest brother of the late eminent London Physician, and a man whose name has been long identified with Irish literature and learning of every kind. Either appointment would be favourably received; but to Dr. TODD the Medical School of the University of Dublin owes much of its present prestige, and therefore we would gladly see him in the Provost's seat. Dr. TODD's father, CHARLES HAWKES TODD, was an eminent surgeon, and was President of the Royal College of Surgeons in Ireland.

#### HONOURS TO SANATORIANS.

THE Metropolitan Medical Officers of Health have acquired fresh honour in the election of Mr. SIMON, Medical Officer of the Privy Council, to the Presidency of the Pathological Society of London. The selection is such as to add to the honourable position of the Society, and at the same time do credit to a body of the Profession, whose services to the public have proved most valuable. Mr. SIMON is worthily selected as the representative of such men as Dr. DRUITT, Mr. BARNARD HOLT, and Drs. PAVY and SANDERSON, the Professors of Physiology at Guy's and Middlesex Hospitals.

#### NAVAL ASSISTANT SURGEONS.

OUR readers are tolerably well aware of the attempt of the Admiralty to decoy medical students into the Naval Medical Service, by a process of serfdom hitherto unknown in the history of our Profession. We refer to the proposal of my lords to pay a sum of money to medical students of a certain standing, they agreeing to become Naval Assistant Surgeons, and binding themselves to serve as such for a term of years.

The Medical Department of the Navy must be essentially rotten when such a proposal as this could be for a moment entertained by the authorities; but what concerns us chiefly is, that our Profession should be so esteemed by my lords as it manifestly is, when such a degrading offer could for a moment be made. For this offer is, in effect, tantamount to saying:—"We will not give the Naval Assistant Surgeons what is fair, but we will undersell the Medical Profession by getting in a lot of students who will do our business well enough, and who, from their exigencies, will gladly take our bounty money, and enlist as private soldiers and seamen do."

In London the medical students have held an indignation meeting, and scouted the proposals of the Admiralty. By all means let the Dublin students do the same; and let it not be said, to the reproach of the Dublin Schools, that they will be found to supply this class of officers to her Majesty's Navy. If a man wish to be a private soldier or seaman, let him; but if he desire to be a commissioned officer let him never accept a commission on any but honourable terms, and on a footing of perfect equality, in that respect, with all other commissioned officers in the land and sea forces of our Sovereign Lady the Queen.

#### THE WEATHER AND THE PUBLIC HEALTH.

THE effect of the severe frost already tells its tale in the mortality returns. The full effect, indeed, is not yet recorded since the report for the last week (to appear this afternoon), cannot fail to display a further increase in the

deaths, from this cause. Three weekly returns have, however, already been issued during the present year. During the fortnight ending January 19th, the deaths in London were 3605, whereas in the previous fortnight, ending January 5th, there were 2873 deaths in London. This shows an excess of 732 deaths in two weeks, the whole of which may be considered as due to the severity of the weather. The deaths through the calamity in Regent's Park have not yet been returned by the coroner, and are, consequently, not included in this return. The distribution of the excess of the deaths over the five periods of life is seen in the following figures:—Under 20 years of age, 50; from 20 to 40, 85; from 40 to 60, 186; from 60 to 80, 333; and at 80 years and upwards, 78. These figures exemplify the well-established law that the power to resist extreme cold diminishes as age advances. There were last week 312 deaths from zymotic diseases; 308 from bronchitis; 100 from pneumonia; 78 from cardiac diseases, and 189 from phthisis. We append the following details from the official returns:—

“The annual rate of mortality last week was 29 per 1000 in London, 31 in Edinburgh, and 31 in Dublin; 38 in Liverpool, 38 in Manchester, 29 in Salford, 29 in Birmingham, 28 in Leeds, 27 in Sheffield, 29 in Bristol, 42 in Newcastle-upon-Tyne, 28 in Hull, and 35 in Glasgow. The rate in Vienna was 33 per 1000 during the week ending the 12th inst., when the temperature was 10·9 deg. Fahrenheit lower than in the same week in London, where the rate was 32 per 1000.

“At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29·586 in. The barometrical reading decreased from 29·79 in. on Monday, to 29·32 on Thursday. The mean temperature of the air in the week was 26 deg., which is 10·5 deg. below the average of the same week in 50 years (as determined by Mr. Glashier). The entire range of temperature in the week was 21 deg. The mean of the highest temperatures of the water of the Thames was 32·7 deg.; that of the lowest was 31·2 deg. The difference between the mean dew-point temperature and air temperature was 6·1 deg. The mean degree of humidity of the air was 76, complete saturation being represented by 100. The direction of the wind was variable. Snow fell on Wednesday, Thursday, Friday, and Saturday. At Manchester and Eccles the lowest temperatures on Sunday were 12 deg. and 12·5 deg., on Monday 11 deg. and 12 deg., and on Tuesday 9 and 8·7 deg. respectively. At Wakefield on Sunday the lowest temperature was 14 deg. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the southern outfall works, Crossness, in the week ending the 19th of January, was 48,950,585 gallons, or 222,405 cubic metres, weighing about as many tons. In the week ending the 12th of January, 293,759 cubic metres were pumped daily.”

## Notes on Current Topics.

**DESTITUTION IN LONDON.**—After pestilence the famine. Such has long been the course of events, and now a state of destitution bordering on famine is to be witnessed in those parts of the metropolis lately ravaged by cholera. It was estimated that on the last day of the frost at least 22,000 working men had become dependent on the parishes, while immense numbers were seeking relief. From every point the cry for help had gone forth, and the charitable public has been constantly besieged for subscriptions. Besides all this, every street in London witnessed bands of workmen patrolling and singing “All froze out,” as a means of extracting a few pence. We consider that such a

state of affairs shows a miserable break-down in the administration of our Poor-law. No man ought to have to beg or starve. The very object of our law is to preserve every one from starvation, and when it fails in this, reform is imperatively demanded. Let the noble stream of British charity ever flow as freely as now; but it ought not to be called upon to serve as a substitute for an inefficient but expensive legal machinery. The existing destitution is no doubt complicated by the strikes. It appears that the London shipwrights have declined 6s. 6d. per day. For these men we have no pity. When their trades'-union funds are exhausted, the workhouse test is their only resort; but unfortunately there are many other labourers dependent upon these, and who are deprived of work by the obstinate combination of the shipwrights. While, therefore, we withhold all sympathy from men “on strike,” our fullest pity cannot be withheld from those dependent on them. For these, and their wives and little ones, timely aid is needed, and we are glad to find the Mansion-house Committee that did such good service in the cholera has been reconstituted for this purpose. No better method of meeting a sudden emergency has been devised, and we consider the money thus distributed of more real service than indiscriminate alms-giving to those who make great outcry, but are probably less deserving than the majority reached through this agency.

**PROSPECTS OF THE SESSION.**—Among the many rumours of the coming Parliamentary Session are some of interest to the profession. Thus it is confidently asserted that the President of the Poor-law Board is ready to introduce a measure for the improvement of workhouse infirmaries, and the better treatment of casuals. It is not improbable, if the question of Parliamentary reform should be postponed, which some Conservative organs seem to hope may be the case, that sanitary matters of considerable importance will be brought forward. It would be a satisfaction to the profession to be informed whether the Medical Council is prepared to seize any opportunity to press on the Legislature the necessity of amending the Medical Act. It is useless to allude to other subjects the Council might well take up. This and the Pharmacopœia will assuredly more than overburden this dignified and slow-moving body.

**SNOWED UP IN A TRAIN.**—The recent inclement season has brought into greater prominence than ever the carelessness of English railway officials for the comfort of their passengers. Trains have been brought to a standstill by deeply-drifted snow. Travellers have on these occasions been detained many hours—in one instance a whole night—with no protection from the pitiless storms of winter but such as is afforded by the cold, comfortless carriages into which the English public consents to be packed; and this with the thermometer many degrees below the freezing point. Not that we hold directors responsible for the season, the unusual severity of which is attested by the same calamity having befallen trains on the lines of Southern France, but this fact affords a forcible illustration of the long suffering of Englishmen, in spite of their character for grumbling, and their reputed devotion to comfort. French railway carriages—even on lines traversing districts to which thousands of our countrymen annually resort to escape the rigors of an English winter—are always warmed. The floor of each compartment is occupied by coppers or tins filled with hot water, and

covered by carpet. Sometimes we have found them keep the carriage too warm, and accordingly had them removed; but in the cooler months what a comfort they have proved! We have travelled twelve and eighteen hours together without suffering from the cold. Now, why is not the same plan adopted on our railways—at least in the winter? What would not those unhappy ladies who were recently snowed up for a whole night in the “limited mail” have given for such a luxury? By it and a good thick rug they might easily have been protected from the worst consequences of their misfortune. Every engine carries with it an abundant supply of hot water. The price of the foot-warmers could not be very great. We commend the idea to our railway directors, sincerely wishing those who refuse to try the plan may shortly have to pass a night snowed up in a train.

REAPPEARANCE OF CHOLERA.—Under this title some alarming accounts of an alleged new outbreak in the North have appeared. The village of Coxhoe in Durham is the scene of this epidemic, which would appear to have broken out with great virulence one Sunday night; above fifty cases of diarrhoea and cholera having occurred before nine A.M. the next morning. After this forty more cases of diarrhoea and twenty-five of cholera occurred in the week, out of which number twenty-six deaths took place. This, in a population of 1500, is certainly very unusual, and would seem to point to the absorption of poison, rather than to epidemic influence. Yesterday week ten more cases of cholera, of which five proved fatal were reported, besides twenty-three cases of diarrhoea. The circumstances call for a strict enquiry, and although every effort is said to be made to stay the plague, we are not sufficiently aware to how great an extent the narrow stream in front of the pitmen's cottages has been used for domestic purposes.

FILTHY QUACK PAMPHLETS.—There is one particularly offensive kind of quackery deserving more rough treatment than any other. We allude to that which preys upon ignorant young men by placing in their hands descriptions suggestive to the youthful imagination of the very evils they pretend to deplore. The scoundrels who flourish in this manner used to post their filthy advertisements in the public urinals, but some of them are growing bolder and venturing into the streets, with offers of their pamphlets. It has lately become difficult to walk along Piccadilly, Regent-street, and some other thoroughfares without having one of these productions thrust into one's hands. During the last few days we have had the pleasure of committing a number to the flames. Were all the world to follow this example the trade would soon cease to pay and so an end be put to this social nuisance. Unfortunately, human nature is weak, and in youth especially so. Consequently the trash is read and believed, the quack is sought as the only salvation, and the victims ruined in morals as well as in purse. We recently saw a youth of thirteen in a railway carriage deeply engaged in attempting to understand one of these treatises on “Manly Vigour.” The writer began with taking his Maker's name in vain, and went on to declare that the virtues of a certain remedy had been proclaimed by every academy and college at home and abroad, concluding, of course, with the address where the said remedy was to be procured. Such productions as these could never be circulated through respectable publishers or booksellers. They are given away at the corners of streets. We trust that no reputable drug vendor would

sell the nostrum. But is there no method of putting down this unrecognized trade? We have heard of Lord Campbell's act, forbidding the exhibition of obscene pictures and books. Would it not be possible to apply its penalties to those who distribute to our youths in the public streets such indecent printed matter as we have alluded to?

THE POOR RELIEF IN ST. PANCRAS.—A very proper remonstrance has been made against the method of administering relief in this parish. It would appear that on only one day in the week, and at only one place in this enormous parish, can the relief be obtained. The consequence is, that old people often have to be days without food unless some be obtained from private charity. On the other hand, many have to walk long distances in order to obtain it. Until recently, it is stated that the business was got over by about one o'clock; but in consequence of recent pressure, poor people have been kept in these bitter cold days waiting from eleven A.M. to five P.M. At a meeting of the Board of Guardians last Wednesday, a resolution was passed requesting the vestry clerk “to make proper arrangements.” Unless this be immediately done, we hope the Poor-law Board will not hesitate to interfere. The present state of most of the Metropolitan Parishes must be reformed.

THE LONDON SURGICAL HOME AND THE COMMISSIONERS IN LUNACY.—We have recently drawn attention to the manner in which the Lunacy Commissioners watch over every infringement of the laws. Their vigilance is again exemplified in a correspondence that appeared in the *Times* on Thursday. A paragraph respecting the “Home” was inserted in the *Times* on the 15th ult., in which the writer spoke of that institution as designed to relieve certain mental maladies. This at once brought the Commissioners in Lunacy down upon the officers of the Home, with a demand for explanations, and eventually an appeal to Mr. Baker Brown himself, as the Senior Surgeon and Founder of the Institution, to disclaim any intention of making it an Asylum for Lunatics. Mr. Brown has of course very properly replied to this effect. It is easy to understand how a writer in a general newspaper might confound hysteria with mental alienation. The circumstance, however, shows very clearly the vigilance of the Commissioners in Lunacy, and can therefore scarcely be regretted. The correspondence will be found in another column.

MEDICAL MEN.—The daily press is teeming with laudations of the conduct of those medical men, whose humane exertions during the recent calamity in Regent's-park were in so many instances the means of snatching from the jaws of death, those whom, to a casual observer, had apparently succumbed to the watery element into which a hundred had been so suddenly immersed. The press generally is only too pleased to seize an opportunity for promulgating reports of the apparent neglect of duty of a medical officer, and we welcome these expressions of esteem, for a few of its members, as being but types of the whole profession, which, except in very rare instances, has never been found wanting in sympathy, or any of those attributes which commend themselves to all thinking men. The medical profession is indeed a noble institution; look at the hundreds who sacrifice time, and but too often their lives, in trying to ameliorate the troubles, and assuage the sufferings of their fellow-creatures on the battle-

field, in hospitals, amongst fever dens, and in the most trying scenes human eye can witness. Yes, and in the majority of cases without any reward but the inward satisfaction of having done their duty. We say that we welcome these expressions of the press in general, because latterly there has been a tendency, especially in one or two of unevitable notoriety, to come out with flaming leaders, and with abuse, no journal claiming to be called respectable should stoop to use, denouncing medical men as if they were the vilest and most unfeeling of God's creatures; hence the present is a small apology, which we cheerfully accept by way of atonement for past errors of judgment.

ROYAL DUBLIN SOCIETY'S LIBRARY.—A new code of rules has just been issued which virtually makes this library free to the public. As many medical men may wish to read there, we subjoin the most important of the rules, which concerns non-members:—

"20. Admission may also be obtained upon application to the Library Committee, accompanied by such recommendation as they shall deem satisfactory. This application must be in a form provided for the purpose; it must be filled in the applicant's handwriting, and specifying the names in full, age, place of abode, and profession or occupation of the applicant. The recommendation must be founded on personal knowledge of the applicant, and certify his or her intention and ability to make proper use of the Reading Room.

"N.B.—Printed forms of application may be obtained from the Hall Porter."

### SYMPTOMS AND TREATMENT OF HÆMORRHŒA SEROSA.

By Dr. LENEY.

#### HÆMORRHŒA CONTAGIOSA.

In this very contagious outbreak of hæmorrhœa which prevails in this country immediately now, vertigo is rare, as also restlessness and jactitation; oppression of chest is not complained of, neither have we the total loss of muscular power or extreme collapse of countenance with terror. In very rare cases does the whole body assume the blue discoloration, lividity shows itself alone in the face and extremities. The algid stage not so profound. The extremities are not shrunk, nor the skin so deadly cold—nay, in many cases the temperature of the body is but little altered. The tongue moist, of ordinary size, and rarely cold. In the epidemic disease, when asphyxia was complete, the patient lived but a very few hours; not so in this contagious form, asphyxia very soon sets in, and it is perfectly marvellous how long the patient will survive in total pulselessness—viz., from one to five and six days, vomiting and purging are not to the same amount, nor the fluid ejected with such force. In the epidemic hæmorrhœa the evacuations were choleric from first to last; early in this form bile is mixed in the dejections, and in many cases I detected a tinge of bile throughout the attack.

A woman, aged 40 years, being four days pulseless, during which time she had constant sero-albuminous vomiting, purging, and cramps, she now remained for three days in a very collapsed and unsatisfactory condition, when suddenly violent bilious cholera set in; for twenty-four hours she threw up basin upon basin of pure bile, and suffered from severe cramps of the calves of her legs, from this she recovered under large doses of calomel and opium. The cramps in this form are trifling in comparison. The voice not raucous, but clear and weak; respiration easy, not laboured, spasmodic and struggling; on the contrary, breathing is barely perceptible to the bystander, and very audible and clear on auscultation. The vox cholericæ rarely well-marked. Leiperia not distressing; thirst not so

urgent; sense of touch not much diminished; hearing but little impaired. In the epidemic form the eyes sunk deep in their sockets and dark; vision, if any, very imperfect. Not so in this, but the eyes suffused, and conveying the impress of exhaustion, as that of a person suffering from combined fatigue, hunger, and want of sleep. The integuments of the abdomen are not drawn to the spine, absolutely resting on the vertebra; no, but on the contrary, and a most important feature, the stomach and abdomen are full, doughy, and distended. I lay emphasis on this condition, for in the epidemic disease in those cases in which the secretion was retained, no evacuations taking place from stomach or bowels, they proved the most suddenly fatal; and on post-mortem examination both stomach and bowels were found distended with sero-albuminous fluid to bursting. In this outbreak we do not, on visiting a patient, perceive the faint and sickly choleraic odour from the body and evacuations; the cabin may stink, to be sure, but the effluvium of hæmorrhœa causing immediate nausea, followed by anorexia, is absent. Anuria is an early symptom; question the patient, and he tells you he made, for some time, little or no urine. Possibly, on strict investigation, it will be found that anuria precedes emesis or diarrhœa; however, from the onset, secretion of urine is nil, and almost alone on the restoration of the secretion of urine, more especially in children, can we have hope. The majority of the patients pass off comatose without pain or struggle; but with children frequently convulsions precede death owing to uræmia.

In this form also the usual time of seizure is between one o'clock and five o'clock A.M.

Relapses are common in this form, not so in the epidemic.

#### TREATMENT.

In 1832 the eliminative treatment was adopted, and was partially successful; then the treatment consisted in giving a mustard emetic, followed by a dose of castor oil.

From my experience of this outbreak, I look on the eliminative treatment as that in which confidence should be placed; but to be successful it must fulfil two important intentions—first, that of emptying the stomach and bowels of the accumulated poisoned sero-albuminous fluid, and, at the same time, constricting the patulous vessels of the mucous membrane, so as to forbid any further extravasation. These intentions are fulfilled by the following combinations. Give first the following emetic:—

R Sulphatis zinci, ℥j.  
Pulv. sinapis, ℥ij., vel. ℥ss.  
Aque tepidæ, ℥vij. ℥.

This not only unloads the stomach, but the zinc acts as an immediate styptic on the mucous membrane, also allays cramp of stomach and bowels.

In several instances have I given the above emetic; no vomiting consequent on it, but cessation of vomiting, and strange, though the patient had been vomiting up to the moment of taking it, yet retained it, seems to act equally well.

As soon after as may be, give the following draught:—

R Olei ricini.  
— terebinthinæ, aa ℥ss.  
Tinct. capsici, gtt. xx.,  
Aque cinnam. ℥j. ℥. ft. haustus.

This unloads the bowels of the fluid contained in them, and we have no more powerful anti-hæmorrhagic styptic than turpentine. In some cases of adults I continue this treatment throughout, but especially in children have I found it successful.

The mucous membrane being now laid bare to absorption, I shall illustrate by a case the most reliable form of treatment:—

A man, aged 53 years, a most hopeless looking case, indeed on my visit I pronounced him moribund. However, as above treated on the eliminative plan laid down, vomiting, purging,

and cramps, ceased; mucous membrane laid bare to absorption, but pulseless, and no secretion of bile or urine. I gave him the following:—

R. Calomel, gr. ij.  
Capsici, gr. iij. ℥. ft. pil.  
Camphoræ, gr. j.

One such every hour until griping set in, which took place after the sixth pill (he complained bitterly of the griping), but now his pulse was legible for the first time for two days; his voice good and countenance also, if such can be said of a naturally very ugly fellow. I then gave him a dose of castor oil and turpentine, large bilious motions with abundant secretion of urine followed; he at once recovered, and in three days resumed labour. Immediately on seeing my patient I adopt counter-irritation, apply at once to pit of stomach acetum lyttæ, also over the kidneys, or, what suits better, one quart of bran in a flannel bag twelve inches by twelve, dipped in boiling water, then strongly wrung out; sprinkle one surface with half a pint of spirit of turpentine, place this over the kidneys and loins, bind it firmly on with a flannel roller and let it fully irritate the skin.

Much advantage will be derived from the inhalation of dilute oxygen gas, or the burning of touch-paper made from a solution of nitre, to which nitric acid is added.

Turpentine epithem to the whole spinal column, chest, and abdomen, also to the extremities, until heat and redness succeed. As drink, iced water, lemonade, soda-water, butter-milk, and good cider.

Give chicken-broth, arrow-root in milk, or boiled bread and milk.

Should cramp of stomach be much complained of, an enema of half an ounce of ether and thirty-five drops of laudanum in half a pint of gruel.

On convalescence give the following:—

R. Sulphatis quinae, ℥ij.  
Pulv. aluminis, ʒj.  
Acidi sulphurici dil.  
Tinct. capsici, aa ʒj.  
Aque ad ʒx. ℥.

Capt. ʒj. bis terve in die.

If the primary symptom be nausea and anorexia give a stimulant emetic; if diarrhoea, the following pills:—

R. Opii pulv. gr. iij.  
Acet. plumbi, gr. xij.  
Capsici.  
Camphoræ, aa. gr. iv.

Mannæ qs. ut ft. pil octo. capt. j, 2nd. hora.

#### CHILDREN.

This disease has prevailed much with children from infancy to the age of twelve years, and has been extremely fatal amongst them; very many go through the primary symptoms, then linger on for days, and perish of uræmia and convulsions consequent on uræmia.

In children I adopt the same plan of treatment; many I have succeeded with in giving the castor oil and turpentine by the mouth every second or third hour, and enemas of alum in cold water, blisters to pit of stomach early. In children this is very important as they suffer much pain there.

The abdomen freed I give occasionally:—

R. Ol. juniperi, gtt. xvi.  
Spt. æther nit. ʒij.  
— terebinthinæ, ʒij.  
Mucilaginis gum arab, ad ʒij. ℥.

ʒi. 2nd. hora.

Also turpentine epithem to the region of the kidneys.

In some cases the abdomen freed I give one-grain doses of calomel every hour until griping or green stools appear, giving at intervals the diuretic.

## MEDICAL TRIAL.

### BALLARAT COUNTY COURT.

#### MISTAKEN DIAGNOSIS OF OVARIAN TUMOUR.

*Hillas v. R. Wynne.*

THE charges sued for consultation fees, the plaintiff having attended, with another medical man, upon the defendant's wife. In cross-examination by the defendant, the plaintiff said Mrs. Wynne had been operated upon as for a tumour, a previous puncture having been made for dropsy. The defendant said that when the operation was made for tumour the doctors were asked if the patient was pregnant, and they said she was not; but the puncture for tumour entered the head of a perfectly-formed child, and the patient was delivered of a fetus. The defendant added that he brought the case into court on public grounds, as the patient had been negligently treated, and at a cost of £120 to him. The plaintiff admitted that the womb should have been examined per vagina before the puncture, as the patient supposed she was pregnant, but even then abortion would have been procured. The patient was right in this instance, and the doctors wrong, as he admitted, but ordinary care and skill had been used nevertheless. The patient was at death's door when he was called in, and 2½ gallons of water were taken from her. To his Honour—We used percussion and the stethoscope when the patient suspected pregnancy, but we could not detect it, and we supposed there was a tumour as the formation was on one side, whereas pregnancy is an enlargement in the centre of the abdomen. It was perfectly impossible that the fetus could have been punctured, as there was fluid passed through the instrument. Defendant—I saw the puncture myself, your Honour, and so did Mrs. Edward Agar Wynne. Plaintiff—The error was not one of judgment, but one unavoidable, owing to the complication of the case, which was one in which it was almost impossible for the woman to be pregnant. She was almost suffocated by peritoneal dropsy, and when we drew off the fluid there was a lump left in the abdomen, which we inferred to be a tumour. We tapped the affair, and I still think it was an ovarian enlargement. His Honour—Still if you had been aware of her pregnancy you would not have tapped her? Plaintiff—No; I admit that; but it was impossible for us to detect pregnancy. To the defendant—I was not in a "dreadful excited state," nor did I say "we have made a dreadful mistake." I deny it. Defendant—It's false, your Honour. His Honour—In this case you destroyed the child. Plaintiff—That could not be avoided in this case. A certain latitude must be allowed in all these cases. His Honour—I admit that, but what presses upon me is that the medical men ought to have tested for pregnancy. Plaintiff—Yes, your Honour; but in this complicated case we could not well do so. In fact, we believed it was perfectly impossible for a woman so affected to conceive. To Mr. M'Cormick—We attributed the dropsy to a tumour in the ovaries. George Nicholson, surgeon, examined by Mr. M'Cormick, deposed that he attended Mrs. Wynne, and called in the plaintiff in consultation. He had himself been called in two or three years before by Dr. Hudson, the patient having aborted and being then under a dropsical affection. When witness called in the plaintiff they determined on tapping, and also on attempting to cure the cause of the dropsy—viz., a tumour. The patient had been for years the subject of ovarian disease, and what was done was done with the best intentions and from the best judgment available, the test for tumour being the usual one. There was not so much fluid as he expected, and he believed the head of the fetus was not punctured, though in any case he thought abortion would have taken place. He was not sure it was bad practice to puncture, even if pregnancy had been recognized. To the defendant—We did not believe there was pregnancy, and I did not ask the patient as to her feelings in that respect. Mrs. Wynne was a dying woman when we took her in hand, and she has benefited very much by our treatment. I think it no loss to her that she lost her fetus, for I think she could hardly have gone her full time. Defendant to his Honour—Mrs. Wynne has not had a child for twelve years, and has had one abortion. Witness to his Honour—I think that a puncture, even if the patient were pregnant, was not bad practice, as it was necessary to remove the cause of the disease. Plaintiff (to his Honour)—I understood the patient was ill for twelve years from dropsy. Witness—I did not hear the plaintiff admit that a mistake had been committed. James Stewart, surgeon, examined by Mr. M'Cormick, deposed that he attended Mrs.

Wynne five or six years ago for ovarian tumour, and that was the cause of dropsy in the case. He thought it good practice to try and cure the cause, but he did not try by puncture at the earlier stage, as he thought there might be adhesions. He did not treat actively then, as she was not in danger, but subsequently there was danger, and active treatment was necessary. Plaintiff to his Honour—The tumour was not grown sufficiently then. You couldn't find it then, hardly. His Honour—Surely a puncture at the earlier stage would have been as curative as at the later period? Witness—It was not possible at that time to say whether the tumour was solid or contained fluid. I certainly must say that if I had considered the patient pregnant, I would not have punctured for tumour, unless the health of the patient was such as to render it necessary. But of course a medical man is liable to mistakes, and when he has used all the skill and care he can, he is not liable for results. His Honour—But don't you think that it is the duty of a medical man to ask questions, and exhaust all the means available when pregnancy is suspected? Witness—Certainly. Dr. Nicholson had evidently made up his mind from the symptoms that the patient was not pregnant. This was the plaintiff's case. The defendant did not call any evidence, and said he relied on the neglect of the plaintiff and his acknowledged fault. His Honour, after some deliberation, said he felt great difficulty in dealing with the case, as the medical witnesses examined were gentlemen of skill. At the same time he felt that the first two witnesses had not exhausted the means of inquiry as to pregnancy, as they had not put questions to the patient on the subject particularly. No doubt the medical men felt that it was absurd in the patient to suppose she was pregnant. They pooh-poohed the patient's supposition, in fact, whereas the patient turned out to be right, and the patient ought to have been asked, as the evidence was that the feelings of pregnancy were different from those caused by a tumour or dropsy. Therefore there had been clearly an oversight in not asking the patient, and on these grounds judgment would be only for the amount paid into court. Judgment, therefore for the amount paid into court.

## SECOND EXAMINATION

### FOR THE DEGREE OF BACHELOR OF MEDICINE.

OXFORD, DECEMBER, 1866.

#### NO. I.—PATHOLOGY.

1. What influences are supposed to favour the deposition of scrofulous material in the lung? What tissues of the organ appear to be primarily concerned therein, and what are the microscopical characteristics of this material?
2. What is meant by Leukæmia, and what are the symptoms which are apt to arise in those affected by it?
3. Enumerate the conditions in which Sugar and Albumen may be found in the urine. What value is to be attached to their presence under various circumstances?
4. Describe the structure of the lesions of the bowels in continued fever and phthisis.
5. Distinguish histologically the several skin diseases vulgarly confounded under the title "Ring-worm."
6. Distinguish between Gout and Rheumatism, acute and chronic.
7. What arguments have been advanced to show a connection between Tubercle, Cancer and Inflammation.
8. What is meant by "Symmetrical Diseases?" Cite some instances.

#### NO. II.—THERAPEUTICS.

1. What would be your treatment of acute Pericarditis in the adult; and by what circumstances would your treatment of this disease be modified?
2. How would you treat a case of Scarlet Fever? What affections are wont to arise in this disease; and what means would you adopt in counteracting them?
3. What line of treatment would you adopt if called to a case of well-marked Tetanus?
4. Comment on the uses of Opium?
5. What precautions against relapse would you recommend to an artisan cured of renal dropsy?
6. What conditions favour the formation of Carbuncles? How do you treat them?
7. What circumstances contraindicate the use of Chloroform?
8. What are the uses of Digitalis?

9. What are the signs of an impacted Gall-stone? What is to be done when it is supposed that a patient is suffering from that cause?

#### NO. III.—FORENSIC MEDICINE AND HYGIENE.

1. What are the symptoms and treatment of (1) poisoning by Opium, and (2) poisoning by Antimony? For what other affections are these forms of poisoning most likely to be mistaken?
2. What mode of procedure would you adopt in trying to detect the presence of Arsenic or Digitalin in the contents of the Stomach?
3. In examining the person of an adult woman who had deposed to a Rape having been forcibly committed on her twelve hours before, what signs would you seek (1) of coition having occurred, so as to legally establish the felony, (2) of consent having been withheld?
4. How would you endeavour to decide whether, in a given case, Suicide is an indication of Insanity?
5. What points would you chiefly observe in trying to identify with a description of a missing person a Skeleton, of which the soft parts had been destroyed?
6. What Disinfectants are now held to be of the most value? Classify and describe their modes of action. How would you treat the clothes of a person affected with Cholera?
7. How do you detect and estimate the impurities which are most commonly found in the Air of a Sick Ward?
8. What are the principal adulterations of Bread?

#### NO. IV.—DISEASES OF WOMEN AND CHILDREN.—PRINCIPLES OF SURGERY.

1. From what various conditions may suppression of Menstruation arise; and how are they to be dealt with respectively?
2. What are the chief causes of Acute Mania in adult women? Describe the affection and its treatment.
3. Under what circumstances is Ovariectomy to be recommended? Describe the operation.
4. What leads you to suspect retroversion of the Uterus? How is it to be treated?
5. Enumerate the causes and modes of treatment (1) of Infantile Paralysis, (2) of Infantile Convulsions.
6. What are the symptoms of Infantile Syphilis?
7. What are the points to observe in the diagnosis of Strangulated Hernia?
8. State fully the symptoms and usual history of Schirrus of the Breast. What reasons incline you to advise or dissuade operation? What treatment other than removal has been recommended?

#### NO. V.—CLINICAL EXAMINATION.

##### (a) At the Radcliffe Infirmary.

1. examine the Patients in the Out-Patients' Hall.
2. Write a Report on the cases of      Ward, and      Ward, giving with care their history, diagnosis, and prognosis, and also the treatment you would recommend. Add such general remarks as occur to you by way of clinical comment on such cases in general.
3. Examine the Urine marked A and B, Microscopically and Chemically, and write a methodical account of your plan of examination.
4. Make a Post-mortem Examination of the Body of in the Mortuary, and demonstrate the Morbid Parts.

##### (b) At the Museum.

5. Describe and sketch from microscopical examination the object marked B.
  6. Describe the preparation marked C.
- The candidates were also required to write translations from the Greek of Aretæus, and from the Latin of Morgagni.

## Correspondence.

### PERREVE'S STRICTURE DILATOR.

MR. BARNARD HOLT'S REPLY TO MR. RICHARDSON.  
TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A very few words will suffice in answer to Mr. Richardson's verbose, personal, and offensive letter. Mr. Richardson, so far as I am concerned, is again in error, and I can only imagine that his anger has warped his judgment. I have neither the time nor the inclination to quarrel with him, and

will therefore dismiss both him and the subject as speedily as possible.

*First.* Perréve's claim to priority of idea was acknowledged by me in my publication in the *Lancet*.

*Secondly.* Vide page 54 of my first edition—I simply claimed the credit which attached to the publication of a series of interesting cases subjected to a novel plan of treatment.

*Thirdly.* I never denied the existence of a directing-rod in Perréve's instrument, but I still maintain that this directing-rod, and the clamps on the handle, will not prevent any other than the very largest tube from being thrust beyond the blades.

*Fourthly.* The paragraph "In the hands of an experienced surgeon," was necessary, for even Mr. Richardson does not know that the tube in Perréve's instrument will project in spite of the directing-rod.

*Fifthly.* Mr. Richardson is again in error. The details of the two instruments are entirely different, and this Mr. Richardson's laboured statement fails to disprove.

*Sixthly.* I again affirm the instrument is equally efficacious where dilatation is desired, the sentence simply referring to the applicability of the instrument, and not to the propriety of the treatment.

*Seventhly.* My information respecting the abandonment of Perréve's instrument was derived from foreign surgeons who have witnessed my operations at the Westminster Hospital.

*And lastly.* My endeavours have been exercised to produce an instrument so simple that it can be used by all members of our profession; and, however much it may annoy Mr. Richardson, I am happy to have succeeded.

In conclusion, I will venture to suggest to Mr. Richardson that he must not say:

"My will is Nature's general law,  
No force arrests my powerful hand,  
No fears my daring courage awe."—*Don Quixote*.

But if he is capable of criticism, he must exercise it in a manner devoid of personalities and offensive expressions. So long as Mr. Richardson's patients have no objection to his preference for Perréve's instrument I am sure I have not, and I apprehend that neither Mr. Macnamara nor Mr. Smyly, who have so successfully treated cases upon the plan I have propounded, will quarrel with him for so doing. It is rather late after six years to endeavour to prove the identity of the two instruments, and I fear some of your readers will conclude that Mr. Richardson is more desirous of quarrelling with his colleague than he is of defending his friend.—I am, sir, your obedient servant,  
BARNARD HOLT.

#### MEDICAL WITNESSES AT PETTY AND QUARTER SESSIONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—If you agree with me in thinking the enclosed correspondence would be interesting to your numerous readers, you will kindly give it a place in your widely-extended journal.

On the 27th September, in the afternoon, two men had an altercation—one of them drew a knife and stabbed the other in the side; same evening he was brought into my surgery by a sergeant of police, and had his wound dressed. Next day being petty sessions day, I was called upon by the presiding magistrate to give evidence, which I did. They not having authority to give any remuneration in such cases, I forwarded a statement of the case to the Chief Secretary, and after some delay I received a letter from Sir T. Larcom, stating that M. Hamilton, Esq., Crown Solicitor, had been instructed to forward me £1 1s., which he did. There was nothing here to complain of.

The case being returned for trial to the Downpatrick Quarter Sessions on the 10th of October, I attended and gave evidence, for which I received an order for £1 1s.; I objected to

the fee. The Sessional Crown Solicitor's *locum tenens* said he could not give more, adding, at the same time:—"We must not squander (?) the public money!" I appealed to the Barrister, stating I never received less at quarter sessions than £2 2s. What, think you, was his rejoinder? "You got too much, perhaps!" These were his exact words. Another medical witness in a waylaying case, the same day (I am at liberty to state this, otherwise the absurdity would not be complete), received an order for £2 2s. Having come to the knowledge of this a few days after, I wrote twice to the Sessional Crown Solicitor requesting an explanation, but he did not deem it fitting to reply to either.

I then addressed the following letter to Sir T. Larcom:—

"Killyleagh, County Down, Nov., 13th, 1866.

"SIR,—Nothing but the importance of the subject—not as it concerns myself individually, but medical witnesses generally—could again induce me to trespass upon your time. The following is a brief statement of facts—namely, on the 10th of October last, I attended at Downpatrick Quarter Sessions, and gave evidence in a case of stabbing, and got an order for £1 1s. I objected, by stating to the court that in the late Sessional Crown Solicitor's time I never received a less fee than £2 2s.; he justly considering that the trouble and loss of time was all the same whether at sessions or assizes. The Barrister said he could not interfere. The same day another medical witness in a waylaying case received an order for £2 2s. Having written twice to Mr. Joshua Magee, Sessional Crown Solicitor, requesting an explanation why one should receive a fee of £2 2s., and the other only £1 1s., to neither of which did he make any reply. Under such circumstances, I am constrained to submit the case to the authorities at Dublin Castle.—I have the honour to be, sir, your obedient servant,

"R. G. SHEIL, M.D.

"Sir Thomas Larcom."

Annexed is the reply:—

"Dublin Castle, 16th Nov., 1866.

"SIR,—I am directed by the Lord Lieutenant to inform you, in reply to your letter of the 13th inst., that the following are the rules laid down by the Attorney-General (August, 1865) for the payment of medical witnesses attending quarter sessions:—"If a medical witness is summoned to sessions in the town where he resides, the usual fee of £1 1s. only is to be paid. Where he is summoned to attend at sessions away from his own residence, he should be paid £1 1s. for every day he is necessarily kept from home, beside his actual travelling expenses, and half a guinea a day for hotel expenses."—I am, sir, your obedient servant,

"THOMAS LARCOM.

"R. G. Sheil, Esq., M.D., Killyleagh."

Taking it for granted (from this) that it was now a matter of plain sailing, I enclosed the subjoined:

"Killyleagh, county Down, 19th Nov., 1866.

"SIR,—I have the honour to acknowledge the receipt of your letter of the 16th inst., No. 20,432, and beg most respectfully to thank you for the information it conveys.

"The rules therein laid down entitles me to travelling and hotel expenses over and above the £1 1s., which I received at the Quarter Sessions on the 10th of October last, the distance from my place to Downpatrick being seven miles (for which distance I am allowed 1s. per mile by the Registrar-General) and being detained there all day.—I have the honour to be, sir, your obedient servant,

"R. G. SHEIL, M.D.

"Sir Thomas Larcom."

To which I received the following reply:—

"Dublin Castle, 30th Nov., 1866.

"SIR,—Referring to my letter of the 16th inst., I am directed by the Lord Lieutenant to inform you that it appears by a report from the Sessional Crown Solicitor that your claim for increased remuneration for your attendance at the Downpatrick Quarter Sessions, last October, was fully considered by the court, and was refused, and also that the case in which you were a witness was disposed of early in the day and did not necessitate your removing from home a night.

"Under these circumstances his Excellency sees no grounds for ordering further payment for your services on the occasion in question.—I am, sir, your obedient servant,

"THOMAS LARCOM.

"R. G. Sheil, Esq., M.D., Killyleagh."

I considered it a duty I owed to myself and to the profession to add, by way of justification for the course I had taken, the subjoined:—

"Killyleagh, County Down, 5th Dec. 1866.

"SIR,—I beg permission for the last time to state that both cases were disposed of in one day, and in the same hour at Downpatrick Quarter Sessions on the 10th of last October, and in neither case were the witnesses obliged to remain 'from home a night,' so that the *anomaly* complained of in my letter of November 13th still remains unexplained, and points in a striking manner to the necessity of more definite legislation on the subject.—I have the honour to be, sir, your obliged and very obedient servant,

"R. G. SHEIL, M.D.

"Sir Thomas Larcom."

The courtesy shown by Sir T. Larcom throughout, must be here acknowledged; the truth is, the evils under which we labour in this particular cannot by justly saddled on the authorities at Dublin Castle, but on the uncertainty of the law (if any) on the subject.

It is admitted on all hands, that no more important evidence, whether as regards the ends of justice, or the life of a fellow being, than that of the medical witness; why then, it may be fairly asked, are we not protected by the Crown on whose errand we are, by an adequate and definite scale of fees over which neither the Court nor Crown Solicitor should have any control.—Yours truly,

R. G. SHEIL, M.D.

#### THE LONDON SURGICAL HOME AND THE COMMISSIONERS IN LUNACY.

The following are the letters, taken from the *Times*, referred to in our "Notes on Current Topics:":—

"Office of Commissioners in Lunacy,  
19, Whitehall-place, S.W., Jan. 3, 1867.

"SIR—I am directed to transmit for your perusal the enclosed copy of a paragraph which appeared in the *Times* newspaper of the 15th ult., and to inform you that the house-surgeon of the London Surgical Home, having attended a meeting of this Board on Monday last to explain that paragraph, then substantially admitted to the Commissioners present the reception into the Home of females of unsound mind.

"The Commissioners will now be glad to hear from yourself, as Senior Surgeon of the Home, whether there is any, and what mistake in the paragraph or on the part of the house-surgeon, as to the objects of the Home, and, if any mistake has arisen, whether you have taken, or intend immediately to take, any and what steps to disabuse the public mind upon the subject of this apparent violation of the Lunacy Law.—I am, sir, your obedient servant,

"CHARLES PALMER PHILLIPS, Secretary.

"I. Baker Brown, Esq."

"136, Harley-street, Cavendish-square, Jan. 5, 1867.

"SIR—In answer to your communication, dated the 3rd inst., I beg to state that the article in the *Times* newspaper to which you refer was written by a gentleman, a perfect stranger to me, who came on the part of the *Times* newspaper, was shown over the Home and supplied with all the papers by the secretary, and I never saw the article until it appeared in print the next morning, was very much vexed at the mistake therein, and instantly took such steps to insure correction as I thought would be sufficient. I have been daily waiting to see my hopes realized, and am now most willing to take any steps the Commissioners may advise to disabuse the public mind upon the subject of any apparent violation of the Lunacy Law.

"I shall be very happy to wait upon the Commissioners to offer any further explanation if they think it necessary.—I remain, your obedient servant,

"Charles Palmer Phillips, Esq."

"I. B. BROWN.

"Office of Commissioners in Lunacy,  
19, Whitehall-place, S.W., Jan. 8, 1867.

"SIR—The Commissioners, observing with pleasure your sense of the gravity of the mistake in the *Times*' article of the 15th ult. upon the London Surgical Home, direct me, to acknowledge their receipt of your letter of the 5th inst., and at

once to obtain from yourself, as senior surgeon of that institution, a plain and direct contradiction of its being open for the reception of females of unsound mind. The Commissioners doubt not that, in possession of such an authoritative contradiction, they will be able themselves to procure for it that necessary publicity which you have hitherto failed to get.—I am, sir, your obedient servant,

"CHARLES PALMER PHILLIPS, Secretary.

"I. Baker Brown, Esq., the London Surgical Home."

"136, Harley-street, Cavendish-square, W.,  
Jan. 10, 1867.

"SIR—I have no hesitation at once in stating, as senior surgeon and founder of the London Surgical Home, that the institution is not open for the reception of females of unsound mind, and in no papers or advertisements issued or published by authority has it ever been stated so. During last year one patient, a servant, was taken in as suffering from hysteria. I immediately discovered she was of unsound mind, and as quickly as possible had her removed to Hanwell Asylum.—I am, &c.,

"I. B. BROWN.

"To C. P. Phillips, Esq., Secretary to the  
Commissioners in Lunacy, 19, Whitehall-place."

## Medical News.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen having undergone the necessary examinations for the diploma were admitted members of the College, at a meeting of the Court of Examiners on Friday, viz. :—

Messrs. James Reginald Stocker, Guy's Hospital; Frederick Knowles, Farnham, Surrey; and George Rootes, Ross, Hereford, students of Guy's Hospital; John Davies Thomas, L.S.A., Swansea; Nicholas Marshall, St. Austell, Cornwall, of University College; Daniel Costelloe, Canonbury-square; and John Arnold, L.R.C.P.Lond., Demerara, of St. Bartholomew's Hospital; Richard Lestock Edgeworth, M.B., Univer. Dub., Edgeworthstown, county Longford; and Thomas Mawhinny Watt, M.A., Univer. Aberd., Ballyjamesduff, county Cavan, students of the Dublin School; George William Barrall, Bedford, of St. George's Hospital; William Alfred Renshaw, Aston-on-Mersey (Manchester School); Alexander Richardson Haughay, M.B., Univer. Aberd., Bushmill, county Antrim (Edinb. and Glasgow); Frederick Woolhouse, Sheffield; Robert Carlisle Appleton, Stockton-on-Tees; Henry Vining Bryant, Hackney-road, of King's College, and Charles Tennant, Newbottle, Durham, of the Charing-cross Hospital.

It is satisfactory to state that out of the 69 candidates who have been undergoing their examinations during the past three days for the diploma of membership, only nine failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their studies for the full period of six months.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—The following gentlemen obtained the Licence in Medicine during the months of October, November, and December, 1866:—

N. W. Allt, 21, Belgrave-square; L. M. Cordner, 4, Belvidere-place; R. M. Craig, 5, Clanbrassil-place; S. Goodisson, Ennisceorthy; M. Harratty, 11, Phibsborough-road; H. J. Hazlett, Lurgan; B. Keelan, Carrickmacross; A. J. Law, St. Brelade's, Jersey; R. P. Murphy, Wexford; H. Murray, Faunet; T. Partridge, Birmingham; H. L. Smith, Borris-in-Ossory; J. F. Supple, 45, Grafton-street; H. G. Thompson, Inistiogue; G. H. Tyndall, Gorey; N. Wade, Killocock.

The following gentlemen obtained the Midwifery Diploma during the same period:—

Nathaniel William Allt; G. Archdall, Fivemiletown; Louis Maxwell Cordner; Richard Manifold Craig; H. Davy, Kimmage Lodge; Michael Harratty; Henry James Hazlett; John James Hurley; Bernard Keelan; Robert Powell Murphy; Henry Murray; C. H. Robinson, 6, Merrion-street, Upper; Henry Lionel Smith; James Francis Supple; Henry George Thompson; P. W. Tuite, 43, Longwood-avenue; Nugent Wade.

MEETING OF THE LONGFORD GUARDIANS.—At a large and influential meeting of the Longford Board of Guardians on the 23rd inst. The Earl of Granard, K.P., in the chair, on the motion of M. W. O'Connor, Esq., J.P., D.C., seconded by H. O. F. Gregory, Esq., J.P., it was unanimously resolved that the salary of Dr. Nicolls, medical officer, be advanced from £90 to £100 a year.

On Monday, the Master of the Rolls gave judgment in a very interesting will case. A wealthy lady of Fox-

cote, near Dudley, named Miss Pargeter, who died about a year ago, was found to have left a will in which, after making large devises and bequests to friends and relatives, she left also the Foxcote estate and the residuary estate, which latter is alone valued at £160,000 to her medical attendant, Mr. Badley, and his son, for the purpose, it is alleged, of secret charitable trusts, for the benefit of Socinian congregations. The Master decided that by virtue of the law of Mortmain those secret trusts were illegal. Messrs Badley are, therefore, trustees not for the charities, but for the next of kin and heirs-at-law.

**THE HEALTH OF LIVERPOOL.**—A discussion arose at a meeting of the Liverpool Town Council on a proposition of the Dock Board to erect several large blocks of warehouses at some of the new North-end Docks. The chairman (Mr. T. C. Bowring) and several members of the Health Committee attributed much of the high mortality of the borough to the erection of six or seven storied warehouses at the North Docks, which stood as a screen, preventing the river breeze from penetrating to the overcrowded districts. In the south end, where these warehouses did not exist, the mortality was not so high as in the streets at the north end, thus shut in. The discussion was adjourned to give an opportunity for conference with the Dock Board on the question.

**CONTAGIOUS DISEASES.**—A supplement to the *London Gazette*, contains Orders in Council, dated the 10th inst., on the subject of the acts passed relating to infectious diseases—viz., the 6th Geo. IV., chap. 78, repealing the laws relating to quarantine, and making other provisions in lieu thereof, and to the "Diseases Prevention Act of 1865," and also refers to the Orders in Council issued in regard thereto, and directs that the provisions of said acts shall from this date be continued in force in every part of England, and on all parts of the sea within the jurisdiction of the Court of Admiralty within three miles of the coast of England for six months from this date, and that the orders of July 14 and Aug. 25 shall be renewed accordingly for said period; and it is ordered that the term "ship" includes vessel or boat, "master" includes any person in charge of a ship, "cholera" includes choleraic diarrhoea, and "nuisance authority" has the same meaning as the Sanitary Act of 1866. The master of any ship within the district of a "nuisance authority," having on board a person affected with, or body dead of, cholera, or anything that has been exposed to the infection of cholera, shall moor his ship in such a place as the "nuisance authority" directs; and if the "nuisance authority" is informed that cholera exists, or has existed within three days, in a ship in his district, he shall give such directions as are deemed requisite for preventing the spread of the disease. The other orders provide for the enforcing of the regulations authorized by said acts when cholera or infectious diseases appear in a district, union, or parish, to be acted on by boards of guardians, medical officers, and other officers, assistants, and servants of boards of guardians.

**DR. MARY WALKER.**—Among those on the platform at a meeting of the Mile-end Temperance Society, on Saturday week, was Dr. Mary Walker, who appeared in the "bloomer" costume. The *Morning Star* says that upon being asked to speak, Dr. Mary rose, and gave utterance to the following sentiments:—"I am pleased to see you here this evening, because it always does my heart good to see temperance people assemble. I know the effects of intoxicating drinks upon the human system. I have observed as much injury resulting from their use as many of my older friends on the platform. It has happened in the course of human events that in my country (United States) we had a terrible war. I have seen many thousands of soldiers who have been injured by strong drink, and, indeed, many who are now sleeping in their graves would be alive had they not used it as a medicine for their wounds. It is with grief that I hear of medical practitioners prescribing every day of their lives, and to almost every patient they have, something of an intoxicating nature. It is true that great men sometimes commit great errors. I must say that it is my opinion—and I suppose I may express my humble opinion sometimes—that intoxicating drinks, under any circumstances, are unnecessary. I will admit that there are people who may take two or three glasses of wine every day and live to be old men and women, but the majority cannot imbibe in this way, but do themselves harm. It has really pained me when I have seen medical men prescribing a little wine or brandy to infants not a year old. I have long been a teetotaler, and, though in this country I have often been sorely

tempted to take intoxicating drinks, I have never yielded, and do not think I shall."

**AN INSECT THAT IS "NOT PARTICULAR."**—While cockroaches partake largely of the common articles of diet in the ship's stores, they also rather like books, clothes, boots, soap, and corks. They are also partial to lucifer matches, and consider the edges of razors and amputating-knives delicate eating. As to drink, these animals exhibit the same impartiality. Probably they do prefer wines and spirits, but they can nevertheless drink beer with relish, and even suit themselves to circumstances, and imbibe water, either pure or mixed with soap; and if they cannot obtain wine, they find in ink a very good substitute. Cockroaches, I should think, were by no means exempt from the numerous ills that flesh is heir to, and must at times, like human epicures and gourmands, suffer dreadfully from rheums and dyspepsia; for to what else can I attribute their extreme partiality for medicine? "Every man his own doctor" seems to be their motto; and they appear to attach no other meaning to the word "surgeon" than simply something to eat. I speak by experience. As to physic, nothing seems to come wrong to them. If patients on shore were only half as fond of pills and draughts, I, for one, should never go to sea. As to powders, they invariably roll themselves bodily in them; and tinctures they sip all day long. Blistering plaster seems a patent nostrum, which they take internally, for they managed to use up two ounces of mine in as many weeks, and I have no doubt it warmed their insides. I one night left a dozen blue pills carelessly exposed on my little table; soon after I had turned in, I observed the box surrounded by them, and being too lazy to get up, I had to submit to see my pills walked off within a few minutes by a dozen cockroaches, each one carrying a pill. I politely informed them that there was more than a dose for an adult cockroach in each of these pills, but I rather think they did not heed the caution, for next morning the deck of my little cabin was strewn with the dead and dying, some exhibiting all the symptoms of an advanced stage of mercurial salivation, and some still swallowing little morsels of pill, no doubt on the principle of *similia similibus curantur*, from which I argue that cockroaches are homeopaths, although had they adopted the other homeopathic theory first, and taken infinitesimal doses, they would then have experienced the full benefit of that noble doctrine, and the medicine while doing them no good, would have done them just as little harm.—*Chamber's Journal.*

**METHYLATED MEDICINES.**—An important law, which passed in the last Session of Parliament, for preventing the unrestricted use of methylated spirit in the preparation of medicines, came into operation on the 1st inst. The Act states that, "if any person shall use methylated spirit or any derivative thereof in the manufacture, composition, or preparation of any article, as aforesaid, or shall sell or have in his possession any such article in the manufacture, composition, or preparation whereof any methylated spirit, or any derivative thereof, shall have been used, he shall forfeit the sum of £100, and such article shall be forfeited; together with the vessels or packages containing the same." The Pharmaceutical Society, in drawing attention to this important Act, states that so stringent are the regulations of the Commissioners of the Inland Revenue on the subject that the Board will not allow the spirit to be used in the preparation of medicines for internal use for even cattle. Methylated spirit may, however, be used in the preparation of medicines for external application for both man and beast, for burning in lamps, and for use in our anatomical museums, in the preservation of specimens, it has been found a great boon. The saving effected in the Museum of the Royal College of Surgeons alone has been very great; where formerly as much as 25s. per gallon was paid for the pure strong spirit, the methylated can now be obtained for about 4s. 6d. Notwithstanding the nauseous taste of the article, attempts have frequently been made to disguise it, but ineffectually. Only on Monday last a druggist named Clark, residing in the Salt-market, Glasgow, was fined £30 for selling methylated spirit to be used as an intoxicating liquor. The stuff was sold in large quantities as "finish," and its effects on the constitution fully justify its name.

**REMARKABLE CASE OF SUFFOCATION.**—An unusual case of suffocation is reported from West Bromwich. It appears that a man named John Macantire, better known as "Oyster Jack," reached his home about midnight on Saturday last. He had two children living with him, one a boy, aged 11 years, and the other a girl, aged 5. Macantire and family

lived a rather irregular life, but for a long time past he had been a teetotaler, and noted for his steadiness. When he left his little oyster shop for home he took with him the bucket-like stove which sufficed to give him warmth during the day. The cold being intense, he, not satisfied with putting on the bed in which he and the children lay all the available wearing apparel, determined to take his stove upstairs. Unfortunately the room was a very small one—only 9 feet by 8 feet in size—the window was closed, and there was no flue or any other means of ventilation. In this small room he took his stove and went to bed. All Sunday passed without either himself or his children been seen, and when Monday evening arrived without anybody hearing of or seeing them, the neighbours became alarmed, and informed the police. The officers entered the house by means of a ladder. The front room was empty and unfurnished; but on opening the door of the back room they beheld a ghastly spectacle. Macantire and the two children lay side by side in one bed. They were all dead, their mouths covered with foam and partly discoloured. There were no signs of a struggle, and the bed-clothes lay on the bodies without being disordered in the least. The bucket-stove was found to be about one-third full of ashes. It was evident that death had been caused by the fumes from the coke or charcoal which had been used in the stove. Downstairs the supper things were found on the table, and the candle and matches had been put out ready for lighting in the morning.—*Daily Telegraph*.

**THE Accident Insurance Company, Limited,** is formed, with a most respectable direction, for the purpose of continuing the accident portion of the business of the late Accidental and Marine Insurance Corporation. The business it is proposed to continue has been in course of development for a period of sixteen years. In 1865 the company was altered so as to include marine insurances in its operations; but the nature of the businesses was so dissimilar that the two departments were not found to work advantageously together, and marine insurance is not comprehended by the present programme. The claims on accident premiums during the sixteen years averaged 60 per cent. only, leaving a balance of 40 per cent. for commissions and working expenses, and for profit to the proprietors. The business of the company has been to provide an amount at death, from accidental causes, from £50 to £2000, or weekly compensation during complete disablement by accident, from 10s. to £10 per week, or to provide a sum at death and weekly compensation together, at arranged rates of premium, of an exceedingly moderate amount. That the advantages to the community of this system of insurance have been appreciated by the public, the constantly increasing business has shown; and with the excellent working staff of the late company, and a good business to commence with, the new organization can scarcely fail to be very successful. The proposed capital is £50,000, in 25,000 shares of £2 each. The total amount which has been paid in compensation from the commencement of the business is about £228,000.

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

*Shaw*.—The person named is a qualified member of the Medical Profession.

*Clemens*.—Your letter will appear in our next.

*Aural Surgery*.—As I have not seen a reply to "Miser's" request, if he should be still looking for it, I would advise him to take a lady's crocheting needle and pass it as far as he can into the auditory canal, probably it will be obstructed by a quantity of inspissated cerumen, which by turning round the needle he may remove, after that the injection of a little warm water probably will put all right, but if it fail, let him blister behind the ear.

## MEDICAL VACANCIES.

Birmingham Lying-in Hospital—Resident Surgeon.  
Durham County Asylum—Assistant Medical Officer.  
St. Mary's Hospital, Manchester—Resident Medical Officer.  
St. Pancras and Northern Dispensary—Resident Medical Officer.  
St. Pancras Workhouse—Resident Assistant-Surgeon.

## MEDICAL APPOINTMENTS.

ATKINSON, F. P., M.B., has been appointed Senior Resident Surgeon to the Lying-in Hospital and Dispensary for Diseases of Women and Children, Birmingham.

BAEKER, J. C., L.R.C.S.I., has been appointed Junior Assistant Medical Officer to the Lancaster County Lunatic Asylum at Rainhill.

BRAID, J., M.D., has been appointed Medical Officer and Public Vaccinator for District No. 5 of the Cuckfield Union, Sussex, vice W. G. Tiley, M.R.C.S.E., resigned.

COWAN, P., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for District No. 1 and the Workhouse of the Leominster Union, vice J. Beavan, M.R.C.S.E., resigned.

HART, P. J., L.R.C.S.I., has been appointed Medical Officer to the Constabulary, Lawrencetown, county Galway, and Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Lawrencetown Dispensary District of the Ballinasloe Union, county Galway, vice T. A. Vesey, M.B., C.M., appointed to the Rostrevor Dispensary District of the Kilkelk Union.

LIGHTBODY, J., M.D., has been appointed Medical Officer and Public Vaccinator for the Kirkby Moorside Union (including the Workhouse), Yorkshire, vice R. Chapman, M.D., resigned.

MATTERSON, R. T., L.R.C.P.Ed., has been elected Medical Officer and Public Vaccinator for the Newark District of the Newark Union, vice H. R. Smith, M.R.C.S.E., resigned.

M'DOWELL, B. F., M.B., L.R.C.S.I., Physician to the Sailor's Home, Dublin, has been appointed a Visiting Surgeon to the Westmoreland Lock Hospital, Dublin, vice R. H. Emerson, L.R.C.S.Ed., deceased.

MOORE, J. D., M.D., F.L.S., has been appointed Assistant-Surgeon to the 24th Lancashire Artillery Volunteers.

WARDEN, C., M.D., has been elected Honorary Surgeon to the Lying-in Hospital and Dispensary for Diseases of Women and Children, Birmingham.

## MEDICAL DIARY OF THE WEEK.

WEDNESDAY, JAN. 30.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M.

THURSDAY, JAN. 31.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Vibratory Motion."

KING'S COLLEGE MEDICAL SOCIETY.—8 P.M. Dr. Fenn, "On Rheumatism and Allied Affections."

FRIDAY, FEB. 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M.

ROYAL INSTITUTION.—8 P.M. Mr. Scott J. Russell, "On the Crystal Palace Fire."

SATURDAY, FEB. 2.

ROYAL INSTITUTION.—3 P.M. Mr. G. A. Macfarren, "On Harmony."

## Births, Marriages, and Deaths.

### BIRTHS.

BENNETT.—On the 18th ult., at Park-road, Liverpool, the wife of James M. Bennett, M.D., prematurely of a son.

SPICKERNELL.—On the 4th inst., at Eastern-parade, Southsea, the wife of Dr. G. E. Spickernell, of a daughter.

ROBINSON.—On the 6th inst., at Torquay, the wife of Dr. Craven Robinson, of a daughter.

SANDERSON.—On the 12th inst., at Edinburgh, the wife of A. Sanderson, M.D., 1st Regt. of Cavalry H.C., of a son.

ELLIOTT.—On the 17th inst., at St. Martins, Stamford, the wife of George F. Elliott, M.D., of a son.

YELD.—On the 22nd inst., at Bridge-street, Sunderland, the wife of Henry John Yeld, M.D., of a daughter.

### MARRIAGES.

ANDREWS—CRAWFORD.—On the 10th inst., at St. Marys Abbots, Kensington, Alfred B. Andrews, M.R.C.S.E., of Westgate, Canterbury, to Caroline Eliza Newton, daughter of W. S. Crawford, Esq.

SISSONS—SISSONS.—On the 16th inst., at the Parish Church, Sculcoates, Hull, William Harling Sissons, Surgeon, of Burton-upon-Humber, Lincolnshire, to Jane Thompson, second daughter of Thomas Sissons, jun., Esq., of Grosvenor-terrace, Hull.

### DEATHS.

YOUNG.—On the homeward passage from the West Indies, on board the Royal Mail Co.'s Steam-ship *La Plato*, David M. Young, L.R.C.P. Ed.

BOOTH.—On the 15th inst., Isaac Booth, Surgeon, of Burslem, Staffordshire, aged 86.

SPENCER.—On the 16th inst., Griffin Spencer, late Surgeon R.N. Eng., 1807, of Alfreton, Derbyshire, aged 84.

ACKLAND.—On the 17th inst., W. Ackland, Surgeon, of Bideford, Devon, aged 76.

FISHER.—On the 17th inst., Thomas Fisher, M.D., of Appian-way, Upper Leeson-street, Dublin, Assistant Librarian, Trinity College, aged 66.

O'FARRELL.—On January 25th, at 23, Lower Dominick-street, Dublin, Bridget the beloved wife of Surgeon E. G. O'Farrell.

## Original Communications.

PAPERS ON DERMATOLOGY.—No. VI.

PSORIASIS.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW AND EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR DISEASES OF THE SKIN, ETC.

(Continued from 19th Dec., 1866, vol. ii., p. 626.)

C. K., aged 30, and married, by trade a house painter, was admitted to the Dispensary for Diseases of the Skin on the 28th of December, 1865, with a few patches of psoriasis in the vicinities of the joints, particularly of the elbow-joint. He had this affection for some time, and had been treated for it, but had not persevered in the treatment advised by his medical attendant. He had no syphilitic taint, so far as I could ascertain. The form of the disease under which he laboured was that described in my edition of Neligan (p. 251) as psoriasis *aggregata*, the psoriasis *diffusa* of Willan, the psoriasis *confluens* of Rayer, and the psoriasis *vulgaris* of other dermatologists. The patient had no constitutional disturbance or local irritation; no itching or inconvenience of any kind, except the fact of the eruption. In this case I gave an arsenical mixture, containing three minims of Fowler's solution in each half ounce; and I directed him to take one dose thrice daily, immediately after meals, intermitting for a day or two in case arsenical symptoms supervened, and taking two teaspoonsful of Epsom salts once a-week. For a considerable time after he began to take this medicine there were not any apparent signs of amendment, but neither were there any signs of aggravation of the disease, such as most practitioners see in cutaneous cases, when first "put on arsenic," as the phrase is. There were not any signs of arsenical saturation, and therefore I conclude that the action of the medicine was tonic and alterative. The doses were neither increased or decreased, and there was not any local treatment adopted. On the 23rd of February, 1866, he was nearly well, and on the 2nd of March there was scarcely any trace of the eruption to be seen. I have not seen the patient since, so I conclude he was troubled no further with his old enemy; but if so, it was more by good fortune than because of anything else, for he dropped off attending, as so many do, when he thought himself well, and did not persevere in the use of the arsenical solution, as he ought to have done for at least two or three months after all traces of the disease had disappeared.

This is but one instance of several others which I have treated on the same plan, and though there is nothing novel or original in treating this disease by Fowler's solution; yet I think the case in point illustrates the specific action of a single remedy, and shows that many cases of psoriasis may be cured without the adoption of any local treatment whatever, without giving gradually increasing doses as advised by many good authorities, and without evidence of arsenical saturation, which, according to others, is necessary in cases of this kind. Moreover, it shows that such large doses as fifteen minims, as advised by some—and those no mean authorities—are not at all necessary for ordinary purposes.

Following the plan pursued in my former papers, I will now make a few observations on the disease itself, and I shall endeavour to do so as concisely as possible.

PSORIASIS. the *lepra* of the Greeks, the *vittiligo* of Celsus, *lepre* of the French, *der aussatz* of the Germans; *sahafabi* of the Arabian medical writers; and *sappachath* of the Levitical law (Lev. xiii., 2.), may be taken as the representative of the squamous class. Dr. Neligan divided it into psoriasis *guttata*, psoriasis *aggregata*, and psoriasis *lepra* forms. The first two of these varieties may be said to be stages one of the other, although in all cases this is not found to be so, while the third is the *lepra* of some writers, and may be looked on as the typical and fully developed psoriasis with silvery scales arranged in an ovoid or circular

form, and unaccompanied by any constitutional, and, for the most part, by any local irritation.

Dr. McCall Anderson, in his monograph on psoriasis, describes a variety which he calls psoriasis *ruptoides*, because of the disease assuming the shape of large conical crusts, marked by concentric rings. There is also the variety called syphilitic psoriasis, which properly should be classed among the "syphilides," and is therefore outside the range of this paper.

*Causes.*—It is undoubtedly hereditary, but of course not necessarily so, and in short it may be best described as essentially a blood disease. Mr. Erasmus Wilson believes it to be caused by a syphilitic poison, but many other writers are not of this opinion. So far as my experience goes, it occurs chiefly in those whose health is below par, and is more frequent among what we call the better classes, than among our poorer brethren. At least taking patients number for number, I see more cases of it in private than in dispensary practice.

*Diagnosis.*—Many practitioners confound chronic eczema with psoriasis. This I have repeatedly seen to occur; and it is the more remarkable, because while there are several points of non-resemblance between the two affections, there are two which may be readily perceived in almost every case. One is the fact, that in psoriasis the scales are of a bright silvery colour, while the scales or quasi-scales in chronic eczema are not silvery. The other is, that itching is a very marked symptom in chronic eczema, while so far as I have seen, it is almost entirely absent in psoriasis. Dr. McCall Anderson remarks thus on this point, in his monograph already quoted (p. 6): "There is curiously enough, a difference of opinion amongst authors as to whether psoriasis is accompanied or not by irritation of the skin—a difference of opinion which is all the less excusable, seeing that we have not here to do with a question of theory, but of fact. Thus, Hardy states that itching is always present, while Devergie informs us that in uncomplicated cases there is never any itching at all. Hebra, on the other hand, states that the itching is only present when the disease is commencing, or when new points of eruption are making their appearance, and that it never continues uninterruptedly during the whole course of the disease. There can be no doubt that the statement of the last-named observer is substantially correct." The diagnosis of syphilitic from non-syphilitic psoriasis is not so easy a matter as that just now mentioned. The points of resemblance and difference are not few; but perhaps the principal are, that in syphilitic psoriasis, there is the coppery tint of the patches of diseased skin common to all the syphilides, as opposed to the dusky red patches of the non-syphilitic; that the extent of the syphilitic eruption is not commonly as great as that of the non-syphilitic; that the patches in the syphilitic disease are usually small and circular, while in the typical disease they are often large and irregular; and that the syphilitic scales are often grey, as contrasted with the bright silvery colour of those in the non-syphilitic affection. Psoriasis has also been confounded with herpes circinatus and pityriasis rubra.

*Prognosis.*—Mostly favourable, although the disease is essentially chronic, and is very much affected by mental anxiety, particularly among the mercantile classes.

*Pathology.*—According to some strumous, according to others syphilitic; while most French writers consider it to depend on what they call the "Dartrous Diathesis," of which they deem this affection an exemplary illustration.

*Treatment.*—In non-syphilitic cases, arsenic is the best remedy; and in cases in which there is suspicion of a syphilitic taint I always now use Neligan's ioduretted solution of the iodide of potassium and arsenic, prescribed thus:—

R Liquoris Arsenicalis minima octoginta.

Iodidi Potassii grana sexdecim.

Iodi puri, grana quatuor.

Syrupi Florum Aurantii, uncias duas. Solve.

This solution will be found fully described in Professor Macnamara's (sixth) edition of Neligan's Medicines, &c., p. 598; and contains in each fluid dram five minims of

Fowler's solution of iodide of potassium, and a fourth of a grain of iodine.

I prescribe forty minims of it for an adult thrice daily after meals. Sometimes it may be given in water; while at other times it may be advantageously taken in infusion of gentian or duleanara; and it will frequently serve the patient to change the vehicle of its administration from time to time. The effect of this on mind and body is much greater than we should have any reason to expect.

In some cases arsenic must be given to produce the symptoms of arsenical saturation, so well-known as being described by Mr. Hunt; and by Dr. Begbie, in his paper, "On the Use of Arsenic," published in the *Edinburgh Medical Journal* in 1858; but I do not at all think this necessary in ordinary cases.

I may be perhaps excused for quoting from p. 270 of my edition of Neligan on the Skin what I consider an aphorism in the treatment of these cases:—"It generally occurs that in the treatment of scaly diseases by arsenic or by iodine, the eruption at first presents an aggravated appearance, the affected parts exhibiting an irritated aspect, and the scaly desquamation being much augmented; but these symptoms soon pass away, and signs of amendment begin to show themselves." I do not think local applications of much use in psoriasis. The fact that so many are recommended is sufficient on this point, even if one had no personal experience; and when to this we add the consideration of the constitutional nature of the disease it will appear reasonable that local treatment can at best be but palliative. Nevertheless, it is much used in Germany, and by some good physicians at home. I have also used it occasionally with advantage, and I have treated the subject at length at p. 274 of my edition of Neligan.

## CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

### REMARKS ON CHLOROSIS AND HÆMORRHAGE.\*

(Continued from page 73.)

In this disease, "Chlorosis," characterized as it is by a general depression of the vital functions, the wasting of the body is slow; may we not then justly conclude that the activity of the absorbent system is also diminished? and when emaciation does occur, may it not arise more from deficient deposition than from increased absorption? Assuredly in the early stages of this affection, there is scarcely a perceptible amount of emaciation; and it is not until the disease be advanced that this symptom becomes apparent. I have often been struck with the plumpness of those who exhibited unequivocal evidence of the presence of chlorosis, though the same torpor which pervaded the whole system had affected likewise the nutritive function.

The urine in chlorosis possesses distinctive properties of considerable interest: it is usually pale, of low specific gravity, and of a mildly acid reaction; it contains, according to the analyses of Becquerel, a large amount of fixed salts, a small quantity of uric acid, and a very small proportion of urea; the diminution of the urea being both absolute and relative, and always keeping pace with the deficiency of red corpuscles in the blood. The difference between this condition of the urine and that which pre-

vails during the occurrence of hæmorrhage is very striking, and shall be hereafter noticed.

From the general torpor the uterine functions are not exempted; their derangement has been frequently and confidently put forward as the real and efficient cause of this disease, with what amount of truth facts must determine. This opinion derives support from the following considerations:—That chlorosis is especially a feminine disorder; that its origin is often attributed by the patient to a sudden suppression of the catamenia; and that the period of its most frequent occurrence is that of puberty—the period immediately antecedent and subsequent to the establishment of the menstrual discharge. But it must be remembered that this is also the period of the completion of growth; as this period approaches, the various systems undergo rapid development, and then it is, or soon afterwards, that this characteristic pathological state of the blood most frequently arises. To me it has often appeared that chlorosis has a more intimate relation with that epoch of life when the frame has nearly reached its full development, than with the uterine functions. Be that as it may, much stress has been laid upon menstruation, and the derangement of this function has been fixed upon by many as the starting point of the disease.

To what extent do facts and observations sustain this opinion?

In the first place chlorosis is by no means limited to the female sex; and in the next, it may with truth be stated that, in a large proportion of cases, the uterine is not more disturbed than any other vital function; the patient menstruates regularly, but less abundantly than in health, and the fluid excreted is, like the blood, deficient in red corpuscles, and hence in colour less deep. This is the only disturbance of uterine function observable in a considerable proportion of cases of chlorosis; and if the cases be carefully investigated, in which the menses are irregular or suppressed, it will often be found that there existed constitutionally or hereditary a disposition to irregularity or suppression of the monthly discharge. When, however, the disease is far advanced, or extreme in degree, and every vital function impaired, it most commonly happens that this function partakes of the general depression, and either recurs in extremely diminished quantity, and at irregular periods, or altogether ceases. Numerous observations which I have made on this subject lead me to the conclusion, that the irregularity, diminution, and cessation of the uterine function, are the effect, not the cause, of the disease. The derangement of the menses can only be removed by the removal of its cause; the treatment, therefore, best calculated to restore the blood to its normal state is that best suited to the restoration of the healthy uterine action. I have seen cases of this affection treated with no other view than that of reproducing the menstrual discharge, and the treatment has been unsuccessful, because based on an erroneous principle. There is in many cases of chlorosis a profuse and wasting leucorrhœa; this symptom has also been seized upon and announced as a cause; yet this, too, is a consequence, and probably connected with the excess of serum in the blood; like any other prominent symptom, however, arising during the progress of a prolonged disease, it merits especial attention, and requires appropriate local treatment. It is not always safe suddenly and completely to suppress this discharge; it should be moderately checked, whilst the treatment which tends to remove the original disease is steadily employed. It may here be remarked that, in chlorosis, sanguineous exudations are comparatively rare, whilst serous exudations—vaginal, intestinal, pleuritic, peritoneal, cerebral, and subcutaneous, are by no means uncommon. In the management of these affections, whilst local treatment is essentially necessary, the leading object should be to alter and improve the condition of the blood itself. The contrast between the two states, that of chlorosis and that of hæmorrhage, is herein strongly marked; menorrhagia is rare, leucorrhœa by no means uncommon.

Of the characteristic symptoms of chlorosis there is not one more strikingly apparent than the well-known change of colour and complexion by which this disease is recog-

\* The Dublin Quarterly Journal of Medical Science, Nov. 1st, 1846. Reported by John Hill, A.M., M.B.

nized. It is not mere pallor, for many healthy persons are extremely pale, it is a morbid aspect—a peculiar greenish yellow tint, familiar to the observant eye, and best expressed in the appearance of the skin after a bruise or ecchymosis, when, absorption being nearly completed, a slight greenish yellow discoloration of the skin remains for several days. It is this hue of the integuments which has given origin to the popular name of the disease, “the green sickness.” The peculiar complexion of chlorosis depends upon the diminished proportion of red corpuscles in the blood circulating in the capillary system; as the result of which a yellow tint is imparted to the skin, either from the colouring matter of the liquor sanguinis, termed hæmaphæin, or as the direct consequence of the smaller number of red corpuscles in the vessels; since it is well-known to microscopical observers that the colour of an isolated corpuscle is yellow, and that it is only when aggregated in considerable numbers that they appear red. The change of colour above described is not confined to the external skin, the mucous membranes also, though in a less evident degree, participate in the pale and bloodless hue caused by the paucity of the red corpuscles in the capillary vessels.

Having now enumerated what may be termed the essential symptoms of chlorosis—the depression of animal heat, the prostration of the cerebral, nervous, muscular, cardiac, pulmonary, intestinal, and uterine functions, together with the characteristic hue of the tegumentary membranes—it remains to make a few remarks upon other symptoms, some of frequent, others of occasional occurrence, which, though they belong not of necessity to the disease, are nevertheless so apt to arise during its progress, that to omit them would be to leave the history of this affection altogether incomplete.

The history of diseases would be much simplified were the complications, in the order of their frequency, carefully distinguished from the essential symptoms. These complications perplex and prolong the treatment, which, but for them, would be simple, easy, and certain. There are few diseases more completely under the control of remedies than uncomplicated chlorosis. Of the complications there is none more frequent, none more disturbing to the regular course of treatment, than the various neuralgic affections and local pains with which many chlorotic patients are afflicted. There is an intimate connection between chlorosis and hysteria; none are more disposed to become chlorotic than those who are hereditarily or constitutionally predisposed to hysteria. I have seen, during the progress of this affection, every variety of hysterical symptoms to arise; I have also seen it complicated with chorea. Nearly allied to hysteria, if not identical with it, are those spinal tenderesses and irritations which propagate pains to every part of the body. These neuralgic pains are oftentimes so severe that the lives of chlorotic patients are rendered miserable by them; and so harassing that every other feeling and consideration is absorbed in unceasing solicitude for their removal or mitigation.

Many individuals suffer from intense frontal headache either constant or periodical, from acute pain in one or other of the sides, in the epigastric or hypochondriac regions, and sometimes even in the extremities. In such cases the treatment must be complex; yet whilst the leading object—the amelioration of the condition of the blood—should never be lost sight of, the means best calculated to mitigate and remove the neuralgic complication must not be omitted. In some cases, particularly those in which there exists in some part of the spinal column much pain on pressure, with strongly marked evidences of spinal irritation, it may be necessary to detract blood either by cupping or by leeches. Care, however, must be taken that the quantity of blood drawn should be small; leeches should not be too numerously applied, nor a prolonged bleeding from the bites encouraged. The operation of cupping has, in this respect, a great advantage, that there is no after bleeding, and when it can be quickly and dexterously performed it is a superior remedy. I have seen chlorotic patients permanently injured by profuse local bleeding. In general the frequently

repeated application of small blisters on either side of the spine is the preferable mode of treatment. In many cases of spinal irritation the pain and tenderness on pressure are found to exist, not along the line of the spinous processes, but on one or both sides of this line. Moderate pustulation is sometimes more effectual than blisters. For the removal of neuralgia, anodynes, particularly opium, should be sparingly and cautiously given. If it constipate the bowels and diminish the secretions, temporary relief will be often purchased at a dear price. Opium, too, by prostrating the nervous energy, injures the respiratory function, and thus adds to the existing imperfection of the blood. It may be necessary to give an opiate—a night's unbroken rest may not be otherwise attainable; it should, however, be looked upon as a thing of necessity, and should, if possible, in chlorosis be avoided. I have occasionally observed marked advantage from small doses of aconite, and in one case of chlorosis with severe facial neuralgia, a great mitigation of pain was effected by a single dose of the *canabis indica*. All these potent agents, however, which lower the vital energies are ill-suited to a disease, the characteristic of which is to depress, below the normal standard, every function necessary to the maintenance of life. They should be employed cautiously, and should not be long persevered in. The local application of anodynes and sedatives is oftentimes more safe, and in efficacy not inferior to their internal administration. Lint soaked in anodyne lotions, placed upon the painful parts, and overlaid with oiled silk, is in many instances a remedy of value; so likewise is their application over a blistered surface, the cuticle having been removed. The ointment of the sulphate of veratrine (a scruple to an ounce of axunge) I have found particularly efficacious. The neuralgic pain is sometimes, but not often, removed by lightly touching the adjacent skin with heated iron. In all these complications, the first object must be to improve the blood, the second, to remove the neuralgic pains.

(To be continued.)

## Hospital Reports.

### SUMMARY OF REPORTS PUBLISHED DURING 1866.

In this number we present our readers with a carefully compiled summary of the valuable matter included in our Hospital Reports during the year 1866, and comprised in Vols. i. and ii. of THE MEDICAL PRESS AND CIRCULAR. We do not hesitate to express our conviction that this summary will very much enhance the value of these reports, both as furnishing a ready means of reference to those specially interested in any particular disease or operation, and as exhibiting the large amount of valuable matter published in this most practical part of our journal. A journal such as THE MEDICAL PRESS AND CIRCULAR is not only useful as a record of passing events, but also as a register for ready reference in all departments of our profession. It will be seen that the arrangement of names is alphabetical, and the volume and page are given in each case:—

ADAMS, Mr., Surgeon to the London Hospital, treated at that institution a case of Psoas Abscess, in opening which the femoral artery was wounded. The case is detailed at length.—Vol. ii., p. 121.

ALTHAUS, Dr., Physician to the London Infirmary for Epilepsy and Paralysis. (a) The mode of treatment for Epilepsy adopted by Dr. Althaus in this hospital is detailed at length.—Vol. ii., p. 173. (b) Some cases of paralysis treated at this hospital by the same gentleman are given in illustration of the theory, “that that which holds good for the sentient nerves is also, to a certain extent, the case with the motor nerves, which have to be subdivided into three different sets, as regards their relations to Faradisation, galvanisation, and volition.”—Vol. ii., p. 490.

BROWN, Mr. BAKER, Surgeon to the London Surgical

Home.—(a) Three cases treated by this gentleman at the Surgical Home are reported. Case 1 is "Colloid Tumour of Ovaries, Uterus, and Rectum, with Ascites; attempted Extirpation." Case 2 is an "almost solid Tumour, implicating Uterus and Right Ovary, and filling up the cavity of the Pelvis; Partial Extirpation." Death occurred in this and in the preceding case. Case 3, "Dropsy of an Ovule escaped into the Peritoneal Cavity extensively attached to the Omentum; Extirpation; Recovery."—Vol. i., p. 78. (b) Three successfully treated Cases of Ovariectomy, with particulars of the operations, are also given.—Vol. ii., p. 202.

BANKS, Dr., Clinical Physician to Sir Patrick Dun's Hospital.—(a) A most remarkable Case of Cerebro-Spinal Arachnitis treated at this hospital is reported. The report contains a concise account of this disease, with particulars of the post-mortem examination made by Dr. Bennett, University Anatomist. It formed the subject of a leading article in the same number of the journal in which it appeared.—Vol. i., p. 561. (b) Also a Case of Lead Paralysis successfully treated by Electricity is reported.—Vol. ii., p. 488.

BARTON, Mr., Surgeon to the Adelaide Hospital.—A successfully treated case of Strangulated Femoral Hernia, with details of the Operation.—Vol. i., p. 98.

BEIGEL, Dr., Physician to the Metropolitan Free Hospital.—(a) A Case of Whooping-cough cured by Hypodermic Injections of Acetate of Morphia, in doses of one-twelfth of a grain. (b) Also, a Case of Ague in an Adult cured by Hypodermic Injections of the same drug, in doses of one quarter of a grain.—Vol. ii., p. 68.

BRYANT, Mr. Guy's Hospital.—Three Cases of Successful Treatment of Stone in the Bladder by Lithotripsy, with details of operation in each case.—Vol. ii., p. 149.

COLLIS, Mr., Surgeon to the Meath Hospital.—Summary of Operations performed in the Meath Hospital by this gentleman, in May 1866, for Right Femoral Hernia in a Female; Complete Dislocation of both Bones of Right Forearm backwards at the Elbow; Right Femoral Hernia in a Man; Double Hæmiplegia in a Boy; Pannus of Left Eye in a Man; Depressed Fracture of Skull in a Man; Necrosis of Lower End of Right Femur; Vesico-vaginal Fistula.—Vol. i., p. 591.

FERGUSON, Sir Wm. King's College Hospital.—(a) Pulsating Tumour at the Root of the Neck—two cases; Popliteal Aneurism; Tumour in the Hypogastrium, with Undescended Testicles.—Vol. i., p. 100. (b) Also, an Account of an Operation for Cleft Palate; and of a Case in which Sir William tied the Femoral Artery for Popliteal Aneurism.—Vol. i., p. 147. (c) Together with Details of an Operation for the Removal of a large brain-sized Tumour from the Calf of the Leg of a Young Lad.—Vol. i., p. 171.

GRIMSHAW, Dr., Cork-street Fever Hospital, Dublin.—Account of a Case of Typhus Fever with Enteric Symptoms, which terminated in Cholera, and subsequently recovered. The account of this case contains nine sphygmographic illustrations.—Vol. ii., p. 438.

HAMILTON, Mr., Surgeon to the Richmond Hospital.—(a) Three Cases of Chronic Abscess, exemplifying the different methods advantageously used in the treatment of these abscesses according to the peculiar nature of each. These cases are of importance, because such abscesses are frequently mistaken for other surgical affections.—Vol. i., p. 417. (b) Also, a Case of Hysterical Wry-neck; and one of Poisoning by Oxalic Acid, with the unusual occurrence of a *straw-coloured* vomit.—Vol. i., p. 484.

HAYDEN, Dr., Physician to Mater Misericordie Hospital.—(a) A remarkable and fully-detailed Case of Thoracic Aneurism.—Commenced Vol. i., p. 303; concluded Vol. i., p. 449. (b) A Case of Ascites, with Anomalous Thoracic Signs.—Commenced Vol. i., p. 333; concluded, with account of post-mortem examination, Vol. i., p. 563. (c) A remarkable Case of Softening of the Left Anterior Lobe of the Cerebrum, with Right Hemiplegia, and Loss of Speech, exhibiting a striking impairment of the faculty of articulate language.—Vol. i., p. 540. (d) Clinical Re-

port on Three Cases of Cerebro-spinal Arachnitis.—Vol. ii., p. 439. (e) Two Cases of Peritoneal Pneumatosis, which Dr. Hayden regarded as exceptional in regard to many of the features laid down as characteristic of this affection by the late Dr. Graves ("Clinical Medicine," Vol. ii., p. 77).—Vol. ii., p. 540.

HOGAN, Dr., Staff Assistant-Surgeon.—A Complicated Case of Purpura Hæmorrhagica, treated in the General Military Hospital, Phoenix Park, Dublin. This case was fatal, and the report contains an account of the post-mortem examination.—Vol. ii., p. 388.

HUGHES, Dr., Physician to the Mater Misericordie Hospital.—(a) Two Cases of Acute Pneumonia—one treated by tartar emetic, the other by moderate stimulants; recovery and rapid convalescence in both instances. Dr. Hughes holds the opinion that no peculiar or specific treatment is applicable to all cases of acute pneumonia, but that the local inflammation in each case subsides concurrently with the fever.—Vol. i., p. 627. (b) Two Cases of Phthisical Hæmoptysis. In these cases the mode of death was different, but the cause the same. In the one the hæmorrhage was directly fatal, in the other indirectly.—Vol. ii., p. 122.

JAMES, DR. PROSSER., City [of London] Dispensary.—Four Acute Cases, treated by the Internal Administration of Tincture of Aconite. Dr. James employs tincture of aconite in cases in which there is an increase of the heart's action, as a febrifuge, as an anodyne, in cases of nervous excitement, palpitation, and organic cardiac disease.—Vol. ii., p. 121.

LITTLE, Mr., London Hospital.—(a) A Case of Gunshot Fracture of the Temporal and Frontal Bones. (b) Fracture of the Skull from Pistol Shot. These cases of gunshot wounds, occurring in civil practice, are sufficiently interesting to deserve special record.—Vol. ii., p. 221. (c) A Case in which Hernia Protruded between the Femoral Artery and Vein with an account of Mr. Little's operation, and the recovery of the patient.—Vol. ii., p. 618.

LYONS, Dr., Physician to the Hospitals of the House of Industry, Dublin.—1. A Case illustrating the use of Capsicum in the treatment of Delirium Tremens. This mode of treatment has been quoted in various home and foreign journals.—Vol. i., p. 395. 2. A Case of Phantom Tumour of the Abdomen; one of Pneumonia, treated by Tonics; and one of Tubercularization of Lung in which Gangrene of the Brain was found after death.—Vol. i., p. 418. 3. Aphthous and Edematous varieties of Tonsillitis, with remarks on treatment by Caustic and by the Tonsillotome.—Vol. i., p. 449. 4. Dr. Lyons' views on Typhus Gravior, Eruptions in Typhus, and an illustrative Case of Typhoid Fever.—Vol. i., p. 482. 5. Cases of Typhoid Fever, Low Typhus, and "Black Death."—Vol. i., p. 503. 6. A Case of Double Pneumonia, treated on the Tonic plan; and one of Cerebro-Spinal Arachnitis.—Vol. i., p. 539. 7. Cases illustrative of the use of a new febrifuge, "Chlorate of Quina." This preparation has been noticed in various home and foreign journals since its recommendation in our columns.—Vol. i., p. 562. 8. Cases of Rheumatic Fever under Alkaline Treatment.—Vol. i., p. 591. 9. Febris Nigra, or Black Death, further remarks on and statistics of it.—Vol. i., p. 525. 10. Therapeutics Notes on the employment of Capsicum in Delirium Tremens; of the use of Chlorate of Quina; and of a Syrup of the Phosphates of Iron, Quina, and Strychnia.—Vol. i., p. 653. 11. Miscellaneous Notes on Scarlatina and Rheumatic Arthritis; Scarlatina, with Mixed Eruption; Chronic Pericarditis; Acute, Non-Complicated, and Latent Pericarditis; Cerebro-Spinal Arachnitis; and Syrup of the three Phosphates.—Vol. i., p. 682. 12. Two Cases of Arachnitis, chiefly at the base of the Brain; and one of Persistent Partial Dilatation of the Right Pupil without discoverable cause.—Vol. ii., p. 10. 13. Five Cases of Irritable Aorta.—Vol. ii., p. 35. 14. Two Cases of Arachnitis situated at the base of the Brain.—Vol. ii., p. 69. 15. Miscellaneous Notes on Typhoid Fever, Hay Fever, and Hay Asthma.—Vol. ii., p. 98. 16. Three Cases illustrating the Disappearance of Organic Cardiac Murmurs.—Vol. ii., p. 123. 17. A Case of Phthisis

Senilis with Pericarditis, and one of Renal Disease with Bronchial Phthisis.—Vol. ii., p. 149. 18. A Case of English and one of Asiatic Cholera.—Vol. ii., p. 174. 19. Notes on Diarrhoea and Cholera.—Vol. ii., p. 226. 20. Several forms of Emphysema.—Vol. ii., p. 252. 21. Pathological Anatomy and General Pathology of Cholera.—Vol. ii., p. 272. 22. Cholera Typhoid.—Vol. ii., p. 304. 23. Stenosis, with Obstruction of the Aorta.—Vol. ii., p. 333. 24. Treatment of Idiopathic Tetanus by Tobacco and Nicotine.—Vol. ii., p. 572. 25. Two Cases in which Typhus supervened on Typhoid Fever.—Vol. ii., p. 588. 26. Miscellaneous Notes on various subjects already referred to; also on Hypodermic Injections; and on a Case of Pure Non-Complicated double Bell's Paralysis.—Vol. ii., p. 618. 27. A Case of Abscess of the Liver successfully treated by Puncture.—Vol. ii., p. 641.

MAPOTHER, Dr., Surgeon to St. Vincent's Hospital.—(a) A Case of Hysterical Tetanus; one of Dropsy from Bright's Disease; and one of Psoriasis Aggregata, treated by Iodide of Potassium, and then by Donovan's Solution.—Vol. i., p. 365. (b) A Case of Bright's Disease.—Vol. i., p. 396. (c) Acute Rheumatism treated by Blistering.—Vol. i., p. 505. (d) A Case of Fracture of the Neck of the Femur, in which death occurred on the fourth day after the injury, from Fatty Heart.—Vol. i., p. 542.

MOORE, Dr., Physician to Mercer's Hospital.—(a) Four Cases of Loss of Speech (Aphasia) with Hemiplegia. Each of these cases differs from the rest.—Vol. i., p. 681. (b) Clinical Remarks on Exophthalmic Goitre.—Vol. ii., p. 617. (c) Clinical Remarks on Aneurism of the Ascending Aorta; both illustrated with cases.—Vol. ii., p. 640.

O'FERRALL, Dr., Surgeon to St. Vincent's Hospital.—(a) A Case of Treatment of Anthrax by Pressure, in detailing which is given an abstract of Dr. O'Ferrall's well-known plan of treatment for this affection.—Vol. i., p. 484. (b) A Case in which a large Abscess was Treated by Drainage.—Vol. i., p. 592.

PORTER, Mr., Surgeon to the Meath Hospital.—(a) Cases Illustrating the Value of Local Anæsthesia.—Vol. i., p. 395. (b) A Case of Strangulated Femoral Hernia in which the stricture was divided without opening the sac; two Cases of Stricture of the Urethra treated with Holt's Dilator; a Case of Primary Syphilitic Ulcer treated by the Mercurial Vapour Bath.—Vol. i., p. 450. (c) A Case of Varicocele in which Subcutaneous Ligation of the Spermatic Veins was effected by Ricord's Operation; a Case of Epulis in which the Tumour was Removed with the Contiguous Teeth and Subjacent Bone; a Case of Bilateral Talipes Varus: Division of the Tendo-Achillis and Tibialis Anticus on either side; a Case of Deformity of the Lower Lip and Chin from a Cancer, which had been treated with caustics for its removal. In this case Mr. Porter performed Rynd's operation.—Vol. i., p. 505. (d) A Case of Chronic Hydrothorax which was treated by paracentesis and the insertion of a drainage tube; an Indolent and Painful Ulcer of the Leg Treated with Opium; Excision of a Fatty Tumour from the Back; Treatment of a Venous Erectile Tumour on the Face by frequent Punctures with Red Hot Needles; a Case of Colles's Fracture of the Radius.—Vol. i., p. 654. (e) A Case of Fracture of the Inferior Maxilla; treatment of Hyarthrosis of the Knee-Joint by Pressure; Extirpation of the Eye-ball in a Case in which a Tumour Involved the Optic Nerve, and was accompanied with protrusion of the Globe, and Amaurosis.—Vol. i., p. 681. (f) A Case of Epithelioma in the Lower Lip of a Female; Treatment of a Rodent Ulcer at the Inner Side of the Eyebrow with Simpson's Paste; application of Strong Nitric Acid to a Bite in the Leg from a Dog.—Vol. ii., p. 9. (g) Chronic Eczema of the Leg Treated with Carbolic Acid Ointment; Treatment of Chronic Enlargement of the Tonsils with Caustic, and subsequent Amputation with a Tonsil Guillotine; Tenotomy in a Case of Contraction and Fibrous Ankylosis of the Knee-Joint, Forcible Extension of the Leg under the influence of Chloroform.—Vol. ii., p. 35. (h) A Case of Colles's Fracture of the Radius Treated with Gordon's Apparatus; a Case of Excision of Epithelial Cancer in the Lower Lip; a Case in which Palliative

Treatment was applied to Hydrocele of the Tunica Vaginalis Testis.—Vol. ii., p. 68. (i) A Case of Aneurism of the Axillary Artery; and a Case in which Epulis of large size originated in the Tooth Socket.—Vol. ii., p. 97.

RICHARDSON, Mr., Surgeon, to the Adelaide Hospital. (a) A Case of Flap Extraction of Cataract in which spontaneous evolution of the lens occurred; and a remarkable Case of Strangulated Oblique Inguinal Hernia of much surgical interest.—Vol. ii., p. 233. (b) A Case of Stricture of the Urethra, in which marked improvement took place after forced dilatation, during which no blood was lost.—Vol. ii., p. 466.

SMITH, Dr. AQUILLA, Clinical Physician to Sir Patrick Dun's Hospital.—A Case of Bell's Paralysis of the Portio Dura, treated by local electrification with the induced current. Dr. Smith treated this case with a view to show the special therapeutic action of a single remedy.—Vol. i., p. 222.

SMITH, Mr. HENRY, King's College Hospital.—A Case of Chronic Abscess of four years' standing on the right shoulder of a woman, with details of Mr. Smith's operation.—Vol. i., p. 147.

THORWOOD, Dr., City of London Hospital for Diseases of the Chest.—Records of Three Cases treated with the Hypophosphites of Soda and Lime.—Vol. ii., p. 67.

TUFNELL, Mr., Surgeon to the City of Dublin Hospital. Records of Three Cases (various fractures) treated with straw splints.—Vol. i., p. 280.

WALTON, Mr. HAYNES, St. Mary's Hospital.—(a) A Case of Scirrhus; a Case of Amputation of the Foot; and a Case of Hydrocele.—Vol. ii., p. 387. (b) Summary of a Clinical Lecture on Hydrocele.—Vol. ii., p. 489. (c) The same continued.—Vol. ii., p. 507. (d) A Case of Popliteal Aneurism which was treated by Ligation of the Femoral Artery.—Vol. ii., p. 617.

WOOD, Mr., King's College Hospital.—Operation in a Case of Contraction of the Neck from a Burn; Congenital Oblique Hernia operated on by rectangular pins; a Case of Oblique Inguinal Hernia of three years' duration, treated by passing wires above and below the pillars of the canal, and removing them on the sixteenth day.—Vol. i., p. 171.

#### REPORTS WITHOUT ANY AUTHORS NAMES.

Treatment of Cholera in London Hospitals.—Vol. ii., pp. 176, 202, 222, 250, 271, 304, 389, 412.

Treatment of Cholera by Venous Injections.—Vol. ii., pp. 435, 464, 507, 539, 573, 589.

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, JANUARY 18, 1867.

Dr. BUTCHER, President of the College, in the Chair.

Dr. WHARTON exhibited

#### A SPECIMEN OF COMPOUND FRACTURE,

and proceeded to say—On last night week, sir, a couple of ladies were returning home from Baggot-street, where they had been spending the evening. From some cause or other, whether owing to the restiveness of the cab-horse, or from carelessness on the part of the driver, I am unable to say, but the door of the cab in which they were seated burst open, and one of the ladies put out her leg, as she stated, with the view of saving her sister; while in the act of doing this the cab upset, and her leg was caught between the cab and the ground. She remained in this position for fully ten minutes, till sufficient help was obtained to raise the cab. She was brought to the Meath Hospital, and I saw her in half an hour afterwards, and found the state of things which I shall now attempt to describe. There was a large wound in front of the leg, just above the foot. Both bones were broken, and protruded. The limb was somewhat in this position, merely kept together by means of the skin. Upon introducing my finger into the wound, I found what I may describe, in familiar language, as a

thorough smash. Of course, then, this specimen is a compound comminuted fracture of both bones of the leg. On passing my fingers along the outside of the limb, I found this fracture of the fibula just at the astragalus. On passing my finger over the dorsum of the foot, I found considerable depression. The great amount of blood which had been lost, the age of the patient, which was 67 years, induced me to propose immediate amputation. This was at once acceded to by my colleagues I had summoned to my help. The proposal was accepted on the part of the lady, though of course with a good deal of hesitation. The lady survived the operation for very nearly a week. The great amount of blood which had been lost, the extensive wound in front, the age of the patient, convinced us that it was hopeless to attempt to save the limb, and the result of the examination afterwards justified the course we followed. The lady survived the amputation for a week, and she appeared to have died from exhaustion. She became delirious on the day following the operation, which continued, with only slight intervals of reason, till the day of her death. The main artery of the limb was not destroyed. We could feel its pulsation, notwithstanding it appeared to us that the only hope which presented itself was to submit to herself and relatives the propriety of immediate amputation, which was done as soon as she recovered from the prostrate state into which she had been thrown by the first shock of the accident.

OBSERVATIONS ON ACUTE GLOSSITIS, ILLUSTRATED BY SEVEN CASES.

By HENRY GRAY CROLY.

Mr. President—One of the first urgent cases which I was called upon to treat was acute inflammation of the tongue. I had not an opportunity of seeing the disease during my pupillage, though in constant hospital attendance as clinical clerk. Subsequently, however, in the City of Dublin Hospital, I observed and noted several cases of this affection, and since then I have had seven patients suffering from this disease under my own care. I am desirous of bringing those cases under the notice of the Society, as illustrative of glossitis and its treatment, with extracts from medical and surgical writers to further elucidate the subject, concluding with practical observations on the causes and treatment of this important disease. I may mention that at one of the meetings of this Society, about two years since, I had the honour of reading a paper on cancer oris, and at a subsequent meeting a communication on scalds of the glottis. An interesting discussion was elicited on both occasions. The present subject will form a continuation of the previous papers.

ACUTE IDIOPATHIC GLOSSITIS, ENDING IN SUPPURATION, AND FOLLOWED BY ABSCESS AT THE BACK OF THE PHARYNX; RESULT, RECOVERY.

Case 1.—J. M., aged 19 years, a farm labourer, of temperate habits and robust frame, bathed in the sea at Bray on the 17th of August, 1856; did not dry himself sufficiently; got a wetting on his way home; the following day he went to work as usual; reaped corn and worked very hard; on his return home in the evening he was attacked with severe shivering, felt soreness in his throat, and had slight difficulty of swallowing; he tried to work on the next day, but failed; felt his tongue swollen. I was requested to visit him on the 20th instant, by his father, who stated that his son had humps in his throat, and was choking. On arriving at his house I found him sitting up at the fire, with an anxious and flushed countenance; saliva dribbling from his mouth; speech thick and indistinct; tongue swollen and tender to the touch; mucous membrane covering the sublingual space infiltrated, and raised on a level with the top of the teeth; considerable hardness under the chin; pulse 120, and full; patient has not slept since the commencement of the attack. I immediately punctured with a sharp-pointed bistoury the sublingual space, which was followed by a free discharge of blood and serum; prescribed a mixture containing tartar emetic in nauseating doses, administered a brisk purgative, and ordered half a dozen leeches to be applied under the chin. I recommended incisions into the tongue, which were objected to.

August 21st. Tongue swollen and indented by the teeth. It was now evident that matter had formed in the cellular space underneath the tongue, and after considerable persuasion, I was permitted to make an incision under the chin, which I accordingly did, passing the scalpel well up in the *median line*, which gave exit to a large quantity of blood and pus.

22nd. Pus flowing freely through the openings at each side

of the *frænum linguæ*, where I made the punctures, and on pressing the tongue on the dorsum pus escaped in large quantity through the incision beneath the chin. The treatment now consisted in the application of linseed poultices, quinine mixture, and beef-tea. In four days the patient complained of soreness in his throat and difficulty of swallowing. On examination I observed a large abscess at the back of the pharynx, which I opened with a bistoury, guarded with lint nearly to the point. Some very fetid pus was thus evacuated, to the immediate relief of the patient, who steadily improved, and was very soon in the enjoyment of his usual health.

ACUTE IDIOPATHIC GLOSSITIS, INVOLVING THE LEFT HALF OF THE ORGAN ONLY, ENDING IN RESOLUTION.

Case 2.—J. K., aged 38 years, of temperate habits, but an inveterate smoker, by occupation a warder in the Spike Island Government Convict Prison, of which I had charge; had not been exposed to wet or cold lately; could not assign any reason for the attack. This man presented himself at the prescribing-room attached to the hospital on the morning of the 20th of November, 1860, complaining of sore throat, accompanied with pain and difficulty in swallowing; he was much disturbed during the night, slept badly, and started up frightened by unpleasant dreams; his speech was thicker than usual, and his expression presented much anxiety. I made a careful examination of his throat, but found the tonsils, uvula, and palatine arches free from even slight efflorescence; he winced when I made pressure with my finger on the base of his tongue, particularly when I pressed on the left side of the raphe. I ordered the man to be admitted at once into the hospital and prescribed a purgative.

November 21st. Patient has not slept; his bowels were freely acted on by the medicine; there is a slight swelling of the left side of the tongue *near its base*; skin hot and dry. A diaphoretic mixture prescribed.

22nd. Patient's speech is very *thick*; he had a bad night; he says he has *acute pain* in his tongue far back at the left side; countenance not very anxious; he coughs occasionally, and then discharges from his mouth a quantity of viscid ropy mucus; there is a slight swelling under the angle of the left jaw, not so far back as the tonsil, which is very tender to the touch; the tongue is now considerably elevated towards the roof of the mouth at the left side, the right side seems natural; the edges of the organ are red, and the centre covered with a white exudation; the left side of the *apex* has a thick rounded appearance, and contrasts remarkably with the opposite part; the sublingual space is slightly elevated, and the crest running up towards the under surface of the apex of the tongue is visible, but not very distinctly; the patient says he had several severe shivering fits during the night; the saliva dribbles constantly from his mouth. The tongue having been well dried, I applied six leeches on its anterior and left side (a thread was previously passed through the end of each leech), they filled rapidly and fell off; the bleeding was encouraged by gargling with warm water.

23rd. Tongue much less swollen, but still considerably enlarged; the tenderness and swelling continues under the left angle of the jaw; three leeches were applied to the painful part; a soft poultice of linseed-meal was applied when the leeches fell off.

24th. Patient slept well; countenance natural; he was discharged cured in a few days.

ACUTE IDIOPATHIC GLOSSITIS ENGAGING THE ENTIRE TONGUE, TERMINATING IN RESOLUTION, IN A BOY 13 YEARS OLD.

Case reported by Mr. W. I. Wheeler, Purser-Student (now Dr. Wheeler.)

Case 3.—A. L., a delicate-looking boy, aged 13, was admitted into the Children's Ward of the City of Dublin Hospital, on the 12th of November, 1864, under Mr. Croly's care, suffering from inflammation of the tongue. His mother cannot assign any reason for the attack. On admission his countenance was anxious; his tongue much enlarged and protruded from the mouth; his respiration was difficult and he could scarcely swallow. Mr. Croly made a free incision with a sharp-pointed bistoury at each side of the raphe, from which blood and serum flowed profusely. The wounds gaped widely, and as the hæmorrhage continued very smartly, the wounds were plugged with lint; the plugs were removed in a few hours; there was no further bleeding; the little patient was greatly relieved by the prompt treatment.

November 13th. Wounds looked like mere scratches; the boy slept well; took wine and beef-tea; his tongue was entirely in his mouth.

14th. The incisions gaped a little ; patient much improved in strength.

18th. Tongue quite natural ; discharged cured.

ACUTE IDIOPATHIC GLOSSITIS AFFECTING THE LEFT HALF OF THE TONGUE : RESULT : RESOLUTION.

Reported by Mr. (now Dr.) Nugent Wade, Purser-Student.

Case 4.—J. C., aged 30 years, cab driver, was admitted into the City of Dublin Hospital, September 5th, 1865, under the care of Mr. Croly, suffering from inflammation of the tongue.

*Previous History.*—Has always been healthy and temperate ; was not exposed to wet or cold before the present attack ; never took mercury. About a fortnight before admission to hospital he felt a stinging pain under his left eye ; three days subsequently he noticed a swelling under his left jaw-bone (near the angle) ; he slept badly ; his tongue became swollen and painful at the left side ; the swelling increased rapidly in one night, and prevented him taking any breakfast on the following morning.

*State on admission to hospital.*—Left half of tongue very much swollen, protruded from mouth, and indented on left side by the teeth ; anterior surface of the organ covered with white tenacious mucus ; left submaxillary gland considerably enlarged, very hard and extremely painful to the touch ; saliva flows freely from the mouth ; deglutition, articulation, and respiration impaired ; pulse full and frequent ; foetid breath ; teeth loose at left side. Mr. Croly ordered four leeches to be applied to the inflamed submaxillary gland ; hot poultices were kept constantly on, and a gargle of alum and chlorate of potash was prescribed to be used frequently ; a purgative was also administered. The leeches bled copiously, and required matico leaves to arrest the hæmorrhage. The tongue regained its normal appearance, and the patient in a few days was discharged cured.

ACUTE IDIOPATHIC GLOSSITIS INVOLVING THE ENTIRE ORGAN, BUT MORE MARKED AT THE RIGHT SIDE, ENDING IN RESOLUTION.

I am indebted to Dr. Nugent Wade for the notes of this case also.

Case 5.—Christopher Pallas, aged 15 years, a strong healthy-looking boy, by occupation a messenger, was admitted into the City of Dublin Hospital on Thursday, September 7th, 1865, under the care of Mr. Croly, suffering from inflammation of the tongue.

This boy says he caught cold by sleeping out all night on a car (about a week before his admission to hospital) ; on the morning following he felt his throat very sore ; four days subsequently he suffered from severe pain in both ears (worse in the right ear than left) ; his tongue became painful and swollen, and he swallowed with difficulty ; on admission his tongue filled the cavity of the mouth completely ; it projected slightly, and was covered with a white fur. The right half is more enlarged than the left ; foetid saliva dribbles from the mouth ; submaxillary gland hard and painful to the touch ; the patient can with difficulty swallow, even fluids ; articulation imperfect ; speech thick.

Mr. Croly made two parallel incisions in the tongue, one at either side of the raphe. A large quantity of blood, pus, and serum escaped. The patient was directed to wash his mouth with tepid water ; all hæmorrhage ceased very soon ; a purgative was administered, and an antimonial mixture to subdue the inflammatory symptoms.

The patient was discharged cured in a few days.

ACUTE IDIOPATHIC GLOSSITIS, FOLLOWED BY ABSCESS UNDER THE ANGLE OF THE JAW.

Case 6.—M. B., a servant maid, was admitted under my care in the City of Dublin Hospital on the 1st of May, 1865, suffering from acute inflammation of the tongue and sublingual glands. She was sent in to me by Dr. Chapman, Medical Officer to the Donnybrook Dispensary District.

*History.*—She caught cold from wet feet ; had shivering fits ; felt soreness under her tongue ; her voice soon became affected, and the tongue swollen.

The catamenia were irregular of late, and she states that at the period she ought to menstruate her tongue swells ; deglutition caused much annoyance, and she became hot and sick. On admission her tongue was observed to be swollen, and her expression was indicative of the disease ; but the mucous covering of the sublingual region seemed to be more affected than the substance of the tongue itself ; her voice was in-

distinct and speech thick ; she could not bear pressure on the tongue or under the chin.

I made punctures with a sharp-pointed bistoury at each side of the frenum linguae, and also incised the tongue at each side of the raphe ; the hæmorrhage was free, and the patient felt instantaneous relief ; a purgative was prescribed, and hot poultices beneath the chin ; she was also directed to clean her mouth ; warm bath. She remained three weeks in hospital, and was then discharged well. The tongue was restored to its natural size. After her discharge from hospital she got inflammation in the left angle of the jaw ; five leeches were applied ; an abscess formed subsequently in that region, and was opened by Dr. Chapman.

INFLAMMATION OF THE TONGUE FROM ERYSIPELAS, ENDING IN RESOLUTION.

Case 7.—H. S., aged 68 years, was admitted into the City of Dublin Hospital on the 3rd of November, 1866, with a large epulis involving almost the entire right half of the lower jaw. On the 6th of November I removed the half of the maxilla from the articulation. On the 13th instant the patient was attacked with a mild form of erysipelas of the face. On the 15th instant he complained of his tongue being sore ; the organ swelled rapidly, and at my night visit was enormously enlarged and protruded through the wound ; dyspnoea was urgent, and swallowing very difficult. I made free incisions on the anterior surface of the tongue, at the right side of the raphe (the left side was not much infiltrated and did not require incisions). The relief was almost immediate.

The Irish School in this, as in other important medical and surgical diseases, has been foremost in adding to our practical information. Our great clinical teacher Graves, and subsequently Dr. Fleming and Professor Geoghegan, have written ably on this subject.

Graves, in his "Clinical Lectures," says : "True idiopathic glossitis is an extremely rare disease. Frank only saw one case of it during his whole life. Four cases of it have been observed of late in different parts of Europe, one of which is given in a German journal, on the authority of my friend Dr. Götzel of Elbing, a gentleman upon whose accuracy implicit confidence may be placed. In none of these cases, however, was the inflammation limited to one-half of the tongue. Dr. Neligan informs me that he had a case of idiopathic glossitis under his care in Jervis-street Hospital, in the year 1846 ; it occurred in a stout country-man, aged 40, and was caused by his working for some days up to his waist in water. The affection came on with rigors ; the entire organ was engaged and so enormously swollen as to prevent the patient from articulating, swallowing, or closing his mouth. Deep incisions were made transversely into the substance of the organ, which were allowed to bleed freely, and he was put rapidly under the influence of mercury."

Dr. Fleming, in the *Dublin Quarterly Journal of Medical Science*, says : "Inflammatory attacks of the tongue are seldom or never idiopathic, and that the tendency of the affection to attack only one-half of the organ is in practice constant and remarkable." A form of rapid and alarming engorgement of the tongue is also described by this gentleman, who questions that such is a true glossitis, and rather considers it an active hyperæmia of the organ for which he recommends copious leeching locally, and under the chin, or free incisions on one or both sides of the raphe. My father witnessed a very curious occurrence a couple of years ago in the neighbourhood of Rathfarnham, illustrating the rapidity with which engorgement of the tongue may take place. A donkey got his tongue through the ring of the snaffle bridle ; the driver remarked the uneasiness of the animal, and on examining him found his tongue enormously distended with the ring of the bit imbedded deeply in his tongue. My father informed me that the affection resembled very much a well-marked case of paraphimosis ; under his direction the blacksmith filed across the ring, when the tongue almost immediately reassumed its natural appearance." Dr. Fleming next calls special attention to a rare form of inflammation originating in the loose areolar tissue beneath the genio-hyo glossi muscles, and first recognized by uneasiness in the movements of the tongue, and the sensation as if there was a ball or a lump at its base, a fulness under the chin, impeded respiration, loss of power of deglutition, and risk of suffocation. Dr. Fleming considers this to be a most painful affection, and accompanied by an amount of danger, and that danger often instantaneous. The first of my cases coincides with this latter form of the disease described by Dr. Fleming, terminating in abscess under the chin, and the treatment I employed was most successful.

Rapid œdema of the tongue, extending to the larynx, occasionally follows the operation of ligaturing portion of the organ for the purpose of removing a cancerous growth, and may require bronchotomy.

Prolapsus linguæ described by Lassus, is considered to be a congenital affection. Mr. Syme gives the history of three such cases in his "Observations on Clinical Surgery," and cured some of them by pressure of bandage and a lotion.

Chelius (by South) speaks of enlargement of the tongue as a congenital affection; "he says this affection must be distinguished from that protrusion which depends on inflammatory swelling."

Yet he does not give any account of acute glossitis.

In THE MEDICAL PRESS for 1860, Professor Geoghegan published a series of seven interesting cases of acute idiopathic glossitis which were under his care in the City of Dublin Hospital. He says: "Acute inflammation of the tongue is generally reported to be a very uncommon affection. Personal experience leads me to doubt the accuracy of such statement, and to surmise that the paucity of recorded cases has been confounded with rarity of the disease."

Case 1.—Acute glossitis terminating in sublingual abscess, and followed by relapse.

Case 2.—Subacute glossitis, terminating in resolution.

Case 3.—Acute glossitis, followed by sublingual abscess.

Case 4.—Acute glossitis; abscess in the muscular substance of the tongue.

Case 5.—Acute glossitis; abscess in the cellular capsule of the sublingual gland.

Case 6.—Acute glossitis; abscess in soft parts beneath the tongue, followed by one in the muscular structure of the organ.

It is remarkable that of these seven cases six terminated in abscess, and only one in resolution.

I find that Dr. Wharton, in THE MEDICAL PRESS (August, 1860), recommends punctures with a lancet beneath the tongue as likely to lessen the tendency to suppuration.

In my Case No. 1, which occurred in 1856, I adopted the practice thus advised by my friend Dr. Wharton with some relief, but not so effectually as to prevent the formation of matter.

Sir Wm. Fergusson, in the last edition of his admirable work on "Practical Surgery" (page 587), published 1857, says:—

"I have seen several instances of remarkable swelling about the tongue which I could not account for from any previous experience. In one of these there was considerable swelling of the organ, copious flow of saliva, difficulty of speech, and remarkable difficulty and pain in deglutition. These features, and considerable œdema about the mucous membrane under the tongue, led me to suspect abscess about the back part of the organ, but a close examination failed to detect the presence of matter. During increased suffering the patient suddenly became aware of the presence of additional fluid in the mouth, and soon perceived a quantity of matter which he supposed had come from about the root of the tongue. There was speedy relief, and the result was all that could be desired. Some time after I saw a case very like this one, and anticipated a similar end; but the patient, a strong middle-aged man, died from exhaustion, without any discharge of matter. In both of these instances the palate, uvula, and tonsils were not involved, so that there was no appearance of ordinary cyanche. In August, 1856, I had to travel some distance to see a gentleman who had been unable to speak or swallow for some days. The pain at the root of his tongue was sufficient to deter him from making any efforts of the kind. On a careful examination I fancied there was a swelling and some fluctuation at the back part of the tongue, near the epiglottis, and, under the impression that matter was there, I made a puncture with a slightly curved lancet, and let out a considerable quantity of fetid pus. The relief was so rapid that the patient could swallow and speak audibly in a few minutes after. Such cases are, in my experience, very rare."

It appears to me remarkable that a surgeon of such undisputed eminence as Sir Wm. Fergusson should not have been familiar with glossitis before the year 1857, when he published the last edition of his work on surgery.

The cases recorded by that gentleman, though not named or classified as glossitis, were evidently of that nature. The first of his cases ended by the abscess opening itself into the mouth; in the second of his cases death occurred without surgical operation; in the third case Sir Wm. Fergusson relieved the patient by incision into the abscess situated at the back part of the tongue near the epiglottis.

The hospital physicians and surgeons of this city have been

long familiar with the symptoms and treatment of this disease in its varied forms.

Having thus detailed the history of seven cases of glossitis which occurred in my own practice (the first in the Enniskerry Hospital, the second in the Hospital attached to the Government Convict Prison at Spike Island, and five in the City of Dublin Hospital, within the last three years), and having quoted extracts from various authorities on the subject, I shall conclude this paper with such practical comments as I think deserving of notice.

The following are the causes of glossitis mentioned by authors:—

1. Exposure to wet and cold (the idiopathic form).
2. Mercurial salivation.
3. Erysipelas spreading through the mouth.
4. Variola, or other eruptive diseases.
5. Stings of wasps or other venomous insects (in fruit season).
6. Wounds of the tongue, such as bites during mastication, or epileptic paroxysms.
7. Burns and scalds.
8. Incautious or accidental mastication of acrid or irritating substances, as briony or wild rice, the mandragora, the aruna, and other poisonous plants. (Copeland saw a case of diffuse asthenic glossitis caused by masticating monkshood through accident.)
9. The excessive use of tobacco.
10. Caustics, acid and acrid chemical compounds. (Hot articles of diet).
11. Operations on the teeth, or for ranula.
12. The administration of mustard has produced it when given in cases of poisoning.
13. Suppression of the menses or other accustomed discharges.

I may here mention that the idiopathic appears to be the most frequent variety of the disease, though generally considered to be very rare. Six of my seven cases were purely of that type, and all of Dr. Geoghegan's were of the same nature. Young and healthy men are most prone to this form of the affection, and the inflammation is most frequently *sthenic* in its character. When produced by excessive mercurial action, or suppression of the salivary flux, there is generally much *tumefaction* than actual inflammation of the organ.

When glossitis occurs as a complication of erysipelas, small-pox, scarlatina, or pestilential maladies, the inflammation is of the *asthenic* type; the symptoms are urgent, and the progress of the disease is rapid; pain and tumefaction are great, and the inflamed parts become livid; the fever is characterized by vital depression, quick and weak pulse, &c; and the variety caused by animal poison or stings of insects often ends in gangrene.

Unlike in its prominent features to other diseases, I do not think it necessary to dwell on its distinguishing features, as I assume no practical surgeon could be mistaken in the diagnosis. From the extreme vascularity of the tongue, and its distensible covering, the organ is liable to swell to an enormous size with great rapidity, and hence the term *erectile glossitis*. When the tongue suppurates the disease is called *suppurative glossitis* (non-frequent, perhaps, when one side only is engaged), whilst the form produced by mercury is called *mercurial glossitis*.

The following are the most prominent symptoms, constitutional and local:—Rigors, pyrexia, headache, soreness in the throat (a symptom almost invariably present), anxiety, and turgescence of countenance; difficulty and pain in swallowing; unquenchable thirst; flow of saliva or mucous fluid; enlargement of sublingual glands; swelling and tenderness about the throat and beneath the lower maxilla; thickness of speech; peculiar voice, pain, redness, swelling, and occasionally protrusion of the tongue and great enlargement of the papillæ; the tongue is more frequently *protruded* from the mouth in the sympathetic forms proceeding from the excessive use of mercury, when the simultaneous affection of the tonsils, parotids, and parts in the vicinity, and the consequent tumefaction of them, press the organ outwards (in proportion to the swelling are the functions of the organ impaired, and in severe cases the voice and speech are much affected); indentation of its edges from the teeth; viscid exudation on its anterior surface. The swelling is best marked towards the base of the tongue and at one side only; the swelling occasionally prevents the epiglottis from rising, and fills up the mouth and isthmus faucium so as to threaten suffocation.

At the commencement the sense of taste is very acute, owing to the excited state of the nerves and increased vascularity of the papillæ; but as the disease proceeds taste is par-

tially destroyed, owing to the pressure on the nervous fibrilla from the turgid vessels and fluid effused into the structure of the organ, and partly to the thick mucus or lymph covering the inflamed surface.

Inflammation of the tongue may terminate in resolution, suppuration, suffocation, or sphacelation.

Abscess in the tongue is said to be rare, owing probably to the muscular structure of the organ. In consequence of the effusion of lymph into the substance of the tongue considerable *hardness* and enlargement sometimes remain long after the acute stage of the disease has been subdued.

N.B. Protrusion of the tongue prevents dyspnœa, as it allows the tongue to remain open.

*Treatment.*—Leeches to the upper surface of the tongue (the organ having been previously well dried); the bleeding from the leech bites to be encouraged by the patient washing out the mouth frequently with warm water; punctures with a lancet beneath the tongue (Velpœau speaks of puncturing the ramid veins); the administration of a purgative and an antimonial mixture when the inflammatory symptoms are high. If the case has not been seen in its early stage, and the symptoms are urgent, no time should be lost in making a free and deep longitudinal incision at either side of the raphe, commencing sufficiently *backwards*, and keeping the edge of the bistoury parallel with the septum to avoid the possibility of injuring the vessels. There is another caution necessary in incising the tongue—the œdema may so far involve only one side, as to cause the *lower* surface, which yields the more readily, to be turned directly *upwards*, in which case the incision made *above* passes into the tissues *normally inferior*. The hæmorrhage from the engorged organ is very considerable, and sometimes alarming to the patient and surgeon, but in the majority of cases it ceases very soon; if the patient be feeble a pledget of lint introduced into the wound will have the desired effect, and was resorted to in one of my cases. Pieces of ice, if at hand, would be of much service in such a case. I find incisions were first recommended by Job Meckren, in the year 1656. They never fail in affording a speedy relief when made sufficiently deep and far back. The incisions gape widely at the time, but in a few hours close, and appear to be mere scratches, and sometimes it is difficult to see them on the following day. I observed in one instance that the wound re-opened.

My friend (and former pupil) Dr. Usher of Tinahely, lately informed me of a case of glossitis which occurred in his neighbourhood; incisions were recommended, but the man refused to submit to the treatment, and died from suffocation.

In a case when the symptoms are too urgent to admit of waiting for the effects of incisions, tracheotomy should be performed without delay.

The patient's strength should be supported by beef-tea, milk, and other unstimulating nutritious articles of diet.

Dr. HENRY KENNEDY—Will you allow me to make one or two remarks on the cases reported by Dr. Croly. I am one of those who look upon true idiopathic glossitis as being extremely rare, and I am inclined to think that many of Dr. Croly's cases might be accounted for in a different way. It appears that some of the patients had suppuration in the neighbourhood of the tongue. This is known to be a very common state, and may probably have given rise to the condition which I think Dr. Croly has too readily concluded to be *glossitis*. I am perfectly familiar with such a state of the tongue, but I have never looked upon it as glossitis. There are several affections of the throat in which the tongue will not bear the slightest degree of pressure. It is swollen and excessively painful, and presents exactly the symptoms which have been detailed this evening. For this reason, I would be inclined to differ with Dr. Croly regarding several of the cases. I think, on the whole, the paper was one of great interest. I might mention, before I sit down, a single case which I recollect, and which came within the category of cases of the kind. A female was given a small quantity of mercury, and salivation resulted. The parts were all swollen, but instead of subsiding, the tongue got larger and larger, and eventually protruded out of the mouth more than two inches. No treatment was of the slightest avail in curing it, and the point of the tongue had actually to be cut off. The woman made a good recovery, though, during the time the tongue was protruding, her sufferings were such as nearly to cost her her life.

Dr. CROLY—Might I ask if Dr. Kennedy had seen many cases of glossitis?

Dr. KENNEDY—I have seen such as those you describe, but I doubt very much they were cases of true glossitis.

Dr. CROLY—I am in a position to state that I saw six or

seven, and that five of my cases were seen and so pronounced by Dr. Geoghegan, who has had much experience in the disease.

Dr. FLEMING said that allusion having been made to his remarks on the subject in Mr. Croly's communication, he would be excused for taking part in the discussion. He fully endorsed the opinions advanced by the gentleman who had last addressed the chair as regarded accuracy of diagnosis; it is imperative. Doubtless, mistakes have been made, and glossitis has been assumed to exist where it did not. The several details specified in his monograph on the subject of "affections of the tongue" having been entered into, it would be inexcusable to trespass further on the time of the Society. Indeed, Mr. Croly has been kind enough to note them, and moreover has recorded the diagnosis and symptoms of glossitis in the accurate acceptance of that term. All surgeons are familiar with those serious subfascial inflammations often assuming the alarming character of "gangrenous cellulitis", destroying the septa of the fascia, investing the several muscles, and even extending to the submental locality, where the symptoms assume all the features already described, and so simulate glossitis. The tongue in such instances is not in the proper sense of the word the seat of glossitis, but the effects are equally destructive to life if free incisions be not made and tension removed, whereby that organ assumes its natural boundaries, and the larynx is freed from any interference with its functions. In the eruptive fevers of children, such as measles, scarlatina, and variola, the hospital surgeon cannot but bring to his mind cases which may be classed under those affections.

Dr. BAXON—I recollect the discussion to which Dr. Croly alludes. It was a very interesting one, and ensued on the reading of his paper. There was one particular point that created a great deal of difference of opinion with regard to the preference to be given to tartar emetic or mercury in these cases. It was the opinion of several gentlemen that the tendency of tartar emetic on young children being to produce a very depressing effect, it should be used very cautiously with them.

Dr. Barton's paper has been unavoidably held over till next week.

#### ARMY MEDICAL DEPARTMENT.

AMONG the statistical reports for the year 1864 (which by-the-bye only came to hand in 1866), we find that the mean strength of white troops at home and abroad was 191,272, somewhat below the average of the aggregate strength for the last four years, which was 199,116·25. The number of deaths was 3085, and the average number for the last four years was 3498. The annual ratio per 1000 of strength for those admitted into hospital was 1119, the annual ratio for the last four years being 1216. The ratio per 1000 for the year of those who died and were discharged invalided were respectively 16·13 and 22·4. The figures for the four previous years 17·57 died and 23·76 discharged invalided, showing a very satisfactory diminution in the mortality and numbers of those invalided.

The Sanitary Report contains a most interesting and valuable paper by Professor Parkes, on hygiene for the year 1865. In it he enters very fully into the theories of the propagation of diseases by "unknown specific agents." After pointing out the facts that no cell or other "independent organization" can be discovered microscopically as carrying the infection, nor any cell growth be detected in the body, the learned Professor goes on to say, on the subject of the cattle plague, "that the virus may be living matter, though the particles have no organized form, but if so, we have still a very imperfect conception of the mode of the action;" and again, "that a discharge virulently contagious may contain no cell form, and the poison appear to reside in granular or formless particles." He gives his opinion that the simply chemical theory is improbable, and that our knowledge is no greater than it was before the researches which were instituted during the cattle plague,

as to the true nature of the virus. In noticing separately the specific diseases, he clearly traces the last cholera epidemic from Alexandria (where it was carried by the pilgrims from Mecca), along the line of commerce, from port to port of the Mediterranean, and finally from Gibraltar to Southampton. We also have very forcibly given the advantages which accrued from the destruction of the stools in the limitation of the epidemic. We recommend the article to the study of all those who have a liking for epidemiological research.

Among the papers in the medical report we notice a very comprehensive article "On the Invaliding and Discharging of Soldiers," by Staff-Surgeon W. J. Fyffe, M.D., Assistant Professor of Medicine in the Army Medical School. It should be read by every assistant-surgeon, and all those who are about to enter the army medical staff. This section of the work also contains a short article "On the Use of the Bromide of Potassium in Cases of very Tight Stricture of the Urethra," by Assistant-Surgeon Lane. We have obtained good results from this salt in cases of irritation of the urethra from other causes, and we think it worth a general trial for the class of case, for which it is advised by Mr. Lane.

The amount of knowledge to be obtained from the perusal of the Reports is very great, and we consider the value of the information contained in them increases year by year.

## Reviews.

LECTURES ON THE STUDY OF FEVER. By ALFRED HUDSON, M.D., M.R.I.A., Physician to the Meath Hospital. 8vo, pp. 336. Dublin: M'Gee. 1867.

IN the preface to this work Dr. Hudson makes a statement which is unfortunately so true that it amounts to an undisputed aphorism, "that the student usually has a less clear idea of fever than of any disease which he meets with in the wards of the hospital." "This difficulty," adds Dr. Hudson, "may arise partly from the want of correspondence of the particular case before him with the description of some form of fever from which he has obtained his *ideal*, and partly from his not possessing the key, so to speak, to its solution in a knowledge of fever in the abstract, of its laws, and of the phenomena which are common to all types of the disease." Accordingly we find that Dr. Hudson's object in the present work is to furnish the student with a guide to his bedside analysis of each case, by treating of febrile phenomena in succession; first, generally or abstractedly, and secondly, in relation to each form of the disease. Beside an introductory lecture delivered at the Meath Hospital in 1864, we have fifteen other lectures, and an appendix, on fever. We have fever considered as one of the group of morbid poisons; a lecture on predisposition; one on the exciting causes; and another on the pathology and symptomatology of fever.

With regard to examining the pulmonary and circulating systems in fever, and to a peculiar form of pneumonia described by Dr. Stokes as occurring in that disease, we find an honourable recognition of the discoveries and labours of Dr. Hudson's most eminent colleague, Dr. Stokes; and this leads us to remark that it is a great pity that, except in a pirated and most incorrect American edition, Dr. Stokes's valuable lectures on fever are inaccessible to the profession. We sincerely hope that Dr. Stokes will do himself tardy justice in this matter, and confer a lasting benefit on the profession by having his lectures on fever published by his own authority in this country.

Dr. Hudson's Lecture VII. treats of the condition of the digestive organs in fever; and is followed by Lecture VIII. on changes in the different secretions. Lectures IX. and X. discuss cerebro-spinal lesions in fever; and Lecture XI. treats of epileptiform convulsions after crisis. Lecture XII. opens another view of the subject, and speaks of the diagnosis of fever as an essential disease. Here we may observe that Dr.

Hudson, like most modern writers, regards typhus and typhoid as essentially different; and in the appendix he singles out Dr. Henry Kennedy as the most prominent advocate of the contrary view, gives a fair analysis of that gentleman's opinions on this point, and combats his deductions with a vigour which is quite refreshing, especially as it is pretty certain to be reciprocated in Dr. Kennedy's next *brochure* on fever. Lecture XIII. describes the history of the disease; its complications; effects of treatment; and prognostic signs at the period of crisis; and Lectures XIV. and XV. travel the round of principle and practice in the most important matter of *treatment*. Dr. Hudson warns the student and practitioner against the possible supervention of perforation of the intestine in typhoid; and observes that, perhaps more cases of perforation occur during convalescence than during fever, and then when least expected. In Lecture XV., speaking of the possibility of *arresting* fever, Dr. Hudson says:—"I believe that hundreds of cases of fever have been thus arrested, chiefly by three measures which medical fashion—rather than reason or experience—has long since consigned to comparative neglect. These are blood-letting, emetics, and cold affusion." Further on, Dr. Hudson condemns the attempt to arrest fever by purgatives; gives specimens of the fearful treatment to which fever patients used to be subjected by being purged *secundem artem*, and concludes by observing: "I have no hesitation in saying that you should never attempt to arrest or shorten fever by the exhibition of purgatives." We certainly think this good advice; and they only who know to what extent purging in fever is still practised throughout Ireland, can properly understand the force of Dr. Hudson's remarks. We knew a fever hospital physician who was a great light in his day, and whose almost invariable rule was to give each fever patient, on admission to hospital, the modest dose of two scruples, then forty grains, of calomel, and a plentiful libation of senna draught after it. We also were acquainted with another who knew nothing at all about such things as ulceration of the intestines in fever; and who accordingly "kept the bowels well opened," until, in not a few cases, the King of Terrors put a stop to the patient taking physic. We cannot see, however, that Dr. Hudson is logical about not arresting fever by purging. Among the objections to the practice raised by him is this, "that there is, perhaps, no instance known of fever being arrested by purgatives." Does not this statement beg the question at issue? For verily the purgers of past days affirmed and believed that hundreds of instances of arrest of fever by purging were to be had; and on this knowledge they based their support of the practice, just as Dr. Hudson now advocates blood-letting and tartar emetic to arrest fever in certain cases, against the views of Sir Thomas Watson, Dr. Todd, and others. The arguments of these physicians he disposes of in a way which seems to us conclusive, according to parity of reasoning, when applied against himself on the question of arrest of fever by purging. We fully agree with Dr. Hudson's views as to the arrest, or proposed arrest, of typhus by purging; but we think Dr. Todd's argument holds good, and that while, in given cases, of which it may be most probably predicated that they are cases of typhus, blood-letting and tartar emetic may, and purging may not, arrest the disease; yet as the late eminent London physician wrote: "If you deal candidly with yourself and others, you must not affirm that you can cut short and cure typhus unless you have the most unequivocal evidence that the cases in question have been examples of that disease."

Dr. Hudson does not share in Sir D. Corrigan's rejection of opium in typhus; but he thinks that chloroform may at times be judiciously substituted for it, and he strongly applauds the late Dr. Graves's well-known plan of treatment by tartar emetic, whether with or without opium.

There are two points in Dr. Hudson's work which we think are especially worthy of imitation by medical writers in the present day. One is the practice, which he has adopted in most of his lectures, of giving a summary of his conclusions on points of doctrine at the close of each discourse; and the other is the frequent references to the writings of other men in the same line. To the opinions and labours of men who are very much his own juniors he pays a respect, and gives a recognition which cannot fail to bring its own reward. For these, among other reasons, Dr. Hudson's book will hold its place as a medical treatise of value, and we hail its publication as another witness to the vitality of the Dublin School, which now, as in the early part of the present century, gives the medical profession of the Irish metropolis a world-wide reputation.

**THE TROPICAL RESIDENT AT HOME.** By EDWARD J. WARING, M.D., Author of "A Manual of Practical Therapeutics;" "An Inquiry into the Statistics and Pathology of some Points connected with Abscess in the Liver," &c., &c. London: John Churchill and Sons.

THE above little work will prove a most invaluable guide to all who have spent a portion of their lives in India or the Colonies, intending to pass the remainder of it at home, whether they have already returned here, or have such a step in contemplation.

Letters are not, as a rule, the most desirable pieces of literary composition to publish in book form; but we may make exception of the volume now before us, and think the author has done good service by publishing what were originally designed for a "few friends." Those who think of finding anything new in tropical life or home pursuits, detailed in the present volume, will be disappointed; while the casual reader will probably be tempted to pronounce it as exceedingly dry—but to neither of these does the author appeal. "Those whom these letters concern" will find much to interest them, and by perusing each carefully, will find a great deal of information which cannot be otherwise than useful. As surgeon in the Indian Army, much experience of tropical life must have been gained, and how far the usages incidental thereto are applicable to England, none can probably speak with greater certainty than Dr. Waring.

Those portions of his letters which treat on matters relative to hygiene—tropical diseases, &c.—deserve particular attention; and his hints on drainage, choice of residence, dress, diet, &c., show how deeply he has dived, even to the minutest particulars, in search of information, which, if followed, will assuredly not cause disappointment to "The Tropical Resident at Home."

**A PRACTICAL TREATISE ON THE PHYSICAL EXPLORATION OF THE CHEST, AND THE DIAGNOSIS OF DISEASES AFFECTING THE RESPIRATORY ORGANS.** By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine in the Bellevue Hospital Medical College, Fellow of the New York Academy of Medicine, &c. Second edition, revised. Pp. 590. Philadelphia: Henry C. Lea. 1866.

THE first edition of this work was published in 1856, and during the time which has since elapsed the author has, as he states in the preface, continued to devote special attention to the diagnosis of diseases affecting the respiratory organs, and he has also given daily lessons in auscultation and percussion at the bedside. For Dr. Flint very justly considers that all written descriptions of the phenomena observed by auscultation and percussion must be imperfect, and that the only method of making the student practically acquainted with the sounds elicited from the chest is by systematic bedside teaching, and he describes the plan pursued by himself in the instruction of his classes. He limits the number of each auscultation class to fifteen, and after explaining and illustrating the acoustic distinctions expressed by the terms intensity, pitch, and quality, he successively introduces the students to patients on whom percussion and auscultation are practised, and from whom each student may learn the distinctive sounds. Premising this observation of the necessity of each student and practitioner making himself personally acquainted with auscultation and percussion, we may state our honest opinion that Dr. Flint's treatise is one of the most trustworthy guides which he can consult. The style is clear and distinct, and is also concise, being free from that tendency to over-requirement and unnecessary minuteness which characterises many works on the same subject. The very attempt to describe with perfect accuracy in words the differences existing between the percussion notes, and between the various auscultation sounds, is a matter of great and almost insuperable difficulty, as each writer or observer has perhaps a mode of appreciating sounds, such as is peculiar to himself, and which he may fail to communicate to others. Hence it is essential that authors should agree, as far as possible, upon certain broad principles which may be generally intelligible, and that minute subdividing should be avoided rather than encouraged. It should be mentioned, however, that one of the chief features in Dr. Flint's treatise is the description of the characters relating to the pitch of the sounds, in conjunction with their intensity and their quality, as he believes that by attention to this point many difficulties of diagnosis may be cleared up, as, for

instance, between the pectoriloquy arising from a solidified lung and that which denotes a pulmonary cavity.

Those who are acquainted with the plan of Dr. Flint's treatise may be informed that after an introduction referring to some preliminary points relating to the anatomy and physiology of the respiratory apparatus, he divides his book into two parts, one describing the different modes of physically exploring the chest, and the other the diagnosis of diseases affecting the lungs.

**ELEMENTS OF CHEMISTRY.** By WILLIAM ALLEN MILLER, M.D. Part 3: Organic Chemistry. Third Edition. Longman, Green, Reader, and Dyer, London. 1867.

By the publication of this part Dr. Miller completes the third edition of his important work—an edition written in conformity with the modern ideas of chemistry, of which, however, the author was not an advocate some years since. We are consequently glad to see his adoption of these views, as it is self-evident that such would not have been the case until after a careful examination of the state of chemistry, and a conviction upon the author's part of the necessity of a radical change.

Dr. Miller, in his preface, says: "The most important changes in the present edition consist in the adoption of a new form of notation, and a recurrence to the system of nomenclature introduced by Berzelius. . . . The general method of classification adopted by that eminent chemist, M. Gerhardt, *Traite de Chimie Organique*, excellent as it is, is not, however, well adapted to the plan of a didactic work like the present, and it was judged preferable, after a preliminary sketch of the methods of investigation and classification employed, to commence the detailed description of the products of organic chemistry, with that of a few of the best known and most familiar compounds derived from the vegetable kingdom."

We could have wished that the author had not adopted the meaningless, barred symbols, to denote equivalents that are doubled. These superfluous hieroglyphics have never been used to any extent in this country, and they are, in our opinion, a mistake.

The table to illustrate the arrangement of compounds in homologous series (p. 41), and other analogous tables, are freely scattered through the work. Dr. Miller is very fond of tables, and very useful they are; many of them will be found quite original in design, and invaluable for the lecture theatre.

The author commences by saying that it is important, *in limine*, to draw a clear distinction between organic compounds and organized bodies. The first class includes such compounds as sugar, oxalic acid, urea, quinia, &c., and are often spoken of as the proximate principles of animal and vegetables. Many of them may be obtained from organic bodies by synthesis.

On the other hand, organized bodies, such as muscular tissue, nervous structure, cellulin and ligneous fibre, never exhibit any tendency to crystalline arrangement, but show a rounded vesicular or fibrous configuration, and are so connected with each other as to form part of a system, each of which is incomplete if severed from the remainder. Bodies such as these cannot be prepared synthetically. The study of the chemical changes that occur during such transformations (the living body assimilating fresh particles, and arranging them in a special form) constitutes physiological chemistry. The author, after dwelling upon this subject for some time, proceeds at once to organic analysis (proximate and ultimate), which forms a fitting introduction to the subject of organic chemistry. In this chapter will be found a description of Mr. Warren's arrangement for fractional distillation, and many novelties and refinements of this branch of practical chemistry. It is here that refinement in apparatus and manipulation is so necessary.

From this the author proceeds to consider the theories on atoms and molecules, chemical types, polyad (polybasic) elements; the latter introducing a description of Crum Brown's graphic formula, lately brought so prominently before the scientific world by the writings of Prof. Frankland. The author does not use this graphic formula, however, any further than a description. As evidence of this edition being completely re-written up to the day, we need not go further than page 64, where the equivalency of thallium is under consideration. The voluminous and important notes would be witnesses of the care which has been bestowed upon this book if others were wanting; but as a rule, voluminous notes are not desirable, and in the present case they might have been often brought into the text with great propriety—*e.g.*, in treating of the amido-acids, the author gives, in the form of a note, a considerable paragraph descriptive of M. Greiss' azotised

bodies produced by the action of nitrous anhydride upon amido-benzoic acid, and such like bodies.—*Vide*, "On a New Class of Compounds containing Nitrogen," &c., P. Griess, *Journal of the Chemical Society*, January, 1867.

The author then goes into the consideration (under the happy term of chemical metamorphoses) of the changes that would come under the designations of oxidation, reduction, and substitution (including double decomposition). The parts devoted to ferments and the artificial bases are most full and valuable.

At page 492, he gives M. Stas' well known process for the extraction of the alkaloids from organic matter. Dr. Miller remarks that chloroform may be often advantageously substituted for ether in that process. The following bases being especially soluble in chloroform—viz., veratria, quinia, brucia, narcotine, atropia, and strychnia. Cinchonia is but sparingly soluble, and morphia still less so.

A peculiar phase of Dr. Miller's book is the manner in which practical or technical matter is inserted on every occasion in connection with the theoretical science. As an instance of what we mean we may give the receipts for different inks under the heads of gallo-tannates, Prussian blue, &c., and a very fair history of the preparation of snuff, as carried on in the Imperial Tobacco Works in Paris, under the head of nicotylia, preparation of leather, &c., &c.

Chap. XIII., "On the Nutrition of Plants and Animals," and Chap. XIV., "On Atomic Volumes, Atomic Heat, and Heat of Combination," bring the volume to a close. They may be received as some of the best constructed portions of this valuable and extensive work on "The Elements of Chemistry."

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 6, 1867.

### THE NEW BRITISH PHARMACOPŒIA.

THE new British Pharmacopœia is now in such a forward state that proof impressions of the volume have been sent to the Members of the Medical Council, and it will be printed and ready for publication in about another month. The statements contained in the *British Medical Journal*, professing to give an account of the contents of the forthcoming volume, are in many respects imperfect, and are, to say the least, premature. It was in fact impossible to describe the new Pharmacopœia, for the same reason as that given in the burlesque play in Sheridan's comedy of the "Critic," where one of the characters is explaining to another why he cannot yet see the Spanish fleet; "the Spanish fleet you cannot see, because it is not yet in sight." The British Pharmacopœia was not in sight—that is to say, it had no definite existence, even in proof, until Friday last, when it emanated from Messrs. Spottiswoode's establishment, and even now it is not in such a condition as to fit it for immediate publication, although, as we have stated, it will be probably ready in a few weeks.

We have been favoured with a sight of the book, and we believe that the alterations made since the appearance of the last edition will be found satisfactory to the Profession in the United Kingdom. A glance at the contents will show that all the objec-

tions formerly offered have been fully and judiciously weighed, and that many, and indeed most, of the recommendations made have been adopted. In the preparation of the Spiritus Ætheris Nitrosi, for instance, instead of the inefficient and absurd process recommended in 1864, a much more simple mode of obtaining the spirit is described. The objectionable plan of indicating the presence of opium in the names of many compounds has been altered, and the Dover's Powder, Paregoric Elixir, Opium Pill, and other preparations containing opium are again called Pulvis Ipecacuanhæ Compositus, Tinctura Camphoræ Composita, Pilula Saponis Composita, Pulvis Kino Compositus, &c.

The two compounds of mercury, lately called calomel and corrosive sublimate, are now called subchloride of mercury and perchloride of mercury, names which, we believe, are free from objection, and really represent, substantially, the chemical nature and relationship of those salts. Many well-known substances, rather arbitrarily excluded from the Pharmacopœia of 1864, have been restored, such as our old friends the acetum scillæ, the acetate of morphia, the iodide of lead, the syrup of buckthorn, the mistura spiritus vini gallici, and several others; and many new and valuable medicines have been added, such as the Calabar bean, the veratrum viride, the oxalate of cerium, sumbul, and many others.

With respect to the new chemical nomenclature now adopted by many scientific societies, it has not been either excluded or recommended in the new Pharmacopœia; but after the name of each chemical substance, both the formulæ are given, the old one first, and the new one side by side with it.

As we before stated, the Pharmacopœia cannot even now be considered in a perfect and complete state, and a few alterations, although probably of a minor character, may yet be made before it comes into the hands of the profession.

### ENGLISH UNIVERSITY EDUCATION FOR MEDICAL MEN.

A PROPOSITION has lately been made at Oxford to establish a Hall for the exclusive use of Medical Students, and there are, no doubt, many arguments that might be used in support of such a scheme, but still when the matter is fairly considered, it will probably be found that the existing arrangements at the Universities, with some necessary modifications, would afford sufficient opportunities for the acquisition of medical study, together with other collateral advantages which the new plan would rather diminish than increase. Professor HUMPHRY, of Cambridge, has recently written a very sensible letter on the subject, and we think that his views will meet with general acceptance, although they are opposed to those which have emanated from the sister university.

In the first place, it must be observed that the majority of the Medical Profession can never be educated, as a great number of English clergymen are, at the English Universities. Unless the whole of the system pursued at Oxford and Cambridge were at once abolished, it would be impossible for the youths destined to the Medical Profession to obtain at either of those seats of learning a Medical Degree or Licence at twenty-one years of age, the time at which most young men expect to find remunerative medical employment. Those Universities insist, and we think rightly, that their alumni should go through a course of preliminary training in general science and literature, before proceeding to their medical studies, and this plan, while it ensures a somewhat higher degree of education, involves a considerably larger expenditure both of time and of money. Besides, it must be stated that residence at either of the English Universities, under any circumstances, is anything but cheap, and although it is true that some industrious students may be lucky enough to obtain Scholarships and other small helps towards their maintenance, yet the college bills always leave a large balance for the student or his relations to pay, and no amount of economy on his part can in any way reduce the items, which are sanctioned by the college authorities and are supported by ancient usages. We entirely exclude the consideration of extravagance, to which college life, however, affords innumerable temptations, but the legitimate charges made for board, lodging, and tuition, are far greater than could be borne by most of those who design their sons for the Medical Profession, and the more especially when it is considered that a much longer time is required to take a Degree in Medicine than to qualify a candidate for Holy Orders. As soon as the student has taken his B.A. Degree he may in a few months, if of the proper age, and after a comparatively small amount of study, be ordained for the Church, whereas the Student of Medicine, after he has passed his B.A. Degree, has several years of study and large expenses still to encounter before he can practise his profession, and even when this object has been attained, he has, perhaps, to wait long before he gains any remunerative employment.

Thus there is no doubt that University residence is necessarily expensive, and especially so, for the reasons we have stated, in the case of Medical Students, but the University authorities are far from wishing to make it any cheaper. For the very fact of its being dear is one of its chief recommendations in the eyes of society in general, and especially of the upper classes, to whom money is no object, and so long as gross extravagance and vice are discouraged and discountenanced, the parents of most pupils find no fault with the charges, and the increasing demand for accommodation at both the Universities proves that the advantages they hold

out are not unfairly paid for by the prices they command. In the case, therefore, of Medical Students, the very poor ones will never think of resorting to the English Universities at all; those who are likely to obtain early employment will grudge the time which they must spend in preliminary studies; and those who do enter are either in easy circumstances, or they can afford to wait some years before entering into practice. Now, these latter form the very class for whom the Universities hold out real advantages, and not so much from the encouragement afforded for the acquisition of scientific knowledge as from the collateral and social benefits obtainable by a University career.

The Medical Profession of the present day can perhaps hardly realise the enormous privileges formerly attainable by the Medical Graduates of Oxford and Cambridge. These favoured individuals formerly became, almost *de facto*, Fellows of the Royal College of Physicians in London, and were appointed, almost exclusively, to the medical posts at the London Hospitals, and thus they necessarily commanded an introduction into the best practice in the metropolis; and although things are now very much altered, yet it must be admitted that the associations formed at college are still found to be of the greatest service in after life. But the value of these associations in a great measure depends upon superior position in life of many of the parties thus thrown together, and all this advantage would vanish if the Universities were made cheap, or if the Medical Students were confined to a single hall, where they would in a measure be cut off from the rest of their fellow-students, and compelled to associate only with their own class.

Dr. HUMPHRY very justly observes that there are Colleges enough already in the two English Universities, and instead of adding another, that the best mode would be to render the existing institutions more available to the wants of the Medical Profession, by such an extension of the teaching as may be most suitable to Medical Students, and by offering a fair share of honour and reward to those who distinguish themselves in Natural and Medical Sciences.

In reference to these last observations much more might be said, and if the history of the different Colleges could be fairly learned, and the present appropriation of the revenues could be examined, we believe it would be found that the authorities, in very many cases, have been very negligent of their duty in not providing rewards for Natural and Medical Sciences as well as for proficiency in Classics and abstract Mathematics, and it is only an act of justice to state, what we believe to be the fact, that several of the Medical Professors both at Oxford and Cambridge are labouring to remove this anomaly.

## THE CASE OF HANCOCK V. PEATY.

IN this case, which has lately occupied for some days the attention of the Divorce Court at Westminster, the petitioner endeavours to set aside a marriage on the ground that the lady was incapable of contracting such a bond in consequence of being insane at the time when the ceremony was performed. The petitioner was the lady's uncle, and one very curious point in the case is, that the married parties are themselves quite satisfied with their condition, and have no wish to change it, and are, in fact, opposing the suit. It is very difficult to understand why the case was brought forward at all, as the details are exceedingly painful, and there is not only no money to be gained on either side, but both parties must lose very considerably in the way of law costs, whatever the issue may be. Ineffectual attempts have already been made to arrange the matter privately, and in order to allow further facilities for such a course the proceedings have been postponed *sine die*, and we believe and hope that the public will hear no more of the suit. The remarks we make have reference only to the points in which our profession is concerned, and these certainly offer some salient marks for comment.

There is, in the first place, much of the usual contradiction of evidence as to the fact of the insanity, for while several of the witnesses, medical and lay, and some of the lady's relatives, positively testify that she was of unsound mind, others, including the husband, other of her relatives, her solicitor, and several more persons, all swear that she has always been perfectly sane, and she herself is now ready to be examined either privately or publicly to prove the fact. Dr. ROBERT LEE, who was called on her part, in support of the validity of the marriage appears to attribute her mental condition to constitutional irregularities, and if he did not directly encourage or recommend the union, he offered no professional objection to it, thinking probably that the change in her condition might have a favourable influence rather than otherwise. It must be stated, however, that nearly all the rest of the medical witnesses, including some *experts*, positively considered her insane, and it is stated that attempts were made to dissuade her from marriage on that ground.

It turns out curiously enough, *apropos* to the recent controversy on clitoridectomy, that this poor lady has been an inmate of MR. BAKER BROWN'S establishment for treating the Surgical Diseases of Females, and it is stated that she there underwent an operation. In the evidence of the husband reported in the *Daily Telegraph*, that gentleman states, that the operation was performed without his consent or knowledge, and that he does not even now know its nature. As this part of the transaction

has, we understand, attracted the attention of the Commissioners in Lunacy, we forbear from making any further remarks at present, the more especially as we anticipate that Mr. BAKER BROWN will offer a full explanation of the case to the Medical Profession.

## Notes on Current Topics.

SCURVY.—Mr. Harry Leach, Resident Medical Officer to the *Dreadnought* Hospital Ship, has again addressed a letter to the *Times* on this subject in which he asks the following questions:—"If bad lime-juice be not provocative of scurvy, how comes it that cases are brought home several years in succession by the same ship, and that the worst cases of this disease are received from certain ports, where the lime-juice is known, and has been proved to be grossly adulterated. How comes it that scurvy will exist in several ships belonging to one firm?" We have already placed the subject before our readers, with an appeal to the sympathy of philanthropists and a remonstrance to the Legislature to interfere and put an end to this infliction. It will be the less necessary therefore for us to refer to it again. We may however observe, before dismissing the subject, that there is no surer sign of the state of a ship's crew than the existence on board of this disease. There must be some defect or some negligence, some shameful disregard to the welfare of the sailor. Bad food or defective lodgings, or both combined, or unwarrantable withholding of a cheap and simple remedy. Pure lime-juice undoubtedly is a specific for the disease, and will prevent the appearance of it in a vessel where the defective quality of the provisions and bad accommodation would be sure to produce it in the absence of that medical agent. Why, then, should not our authorities take measures to ensure to our seamen a supply of that article pure? Competent medical men might be appointed to ascertain that the lime-juice is of proper quality, and that it is properly shipped, and likewise to enquire into the circumstance of any death that may have taken place on the voyage.

HOSPITAL CARRIAGES.—A letter has appeared in the *Times* from Dr. Horace Jeaffreson, Hon. Sec. Hospital Carriage Fund, giving an account of the proceedings of the committee and what they have already done up to the present period in a matter of so much importance as an attempt to render it unnecessary to use the common street cabs for conveyance of invalids, who in certain cases are afflicted with contagious diseases which may be conveyed to the next persons who enter the infected vehicle. This is a subject well deserving the attention of the public generally, as no doubt disease has been unconsciously conveyed in hundreds of instances by this promiscuous employment of these public conveyances. It appears that the sum of £50 has been already subscribed, six hospital carriages have been procured at a cost of 100 guineas each. They have been distributed in the following manner:—The Committee of the London Fever Hospital have given permission to build a station on their grounds in the Liverpool Road for two of these carriages, one for fever, the other for small-pox; all who forward telegraph messages to that address will find these carriages at their service at a very moderate charge for the hire of a horse which is the only

expense that those who use them need incur. The other four have been given to the London, St. George's, St. Mary's, and Middlesex Hospitals, and have been accepted by their respective committees, as all those institutions receive patients with infectious disorders into their wards. Coach-houses will be provided by them for the carriages, and all patients suffering from such diseases will be permitted to avail themselves of this mode of transit whenever they may need to be conveyed to or from these institutions. These committees also readily agreed to use their utmost efforts to carry out the objects contemplated by the committee of the "fund." We very much regret to find that the authorities of the Small-pox Hospital (an institution which ought to be one of the most prominent in giving assistance to an object of this kind) have, for some reason or other, not felt themselves at liberty to follow these laudable examples. We hope the restraint, whatever it be, may soon be removed and that they may not stand aloof from an object which equal to all others demands their approval. Appeal is made by the committee of the fund for pecuniary assistance, which is the more urgent; and as applications are constantly made for a carriage to place in this or that locality, and sometimes a coach-house is offered, but for want of further funds these applications are necessarily refused. There is everything in the construction of these carriages to render them convenient, to give ease to the patient and preserve cleanliness. They are fitted with vulcanized india-rubber air mattress and pillow, which, as well as the hard paint of the interior of the carriage, admit of being washed, and all materials which are found in common street cabs, and which might retain the contagion, such as lining and stuffing, are dispensed with. We trust the efforts of the committee may meet with speedy success, and that the time may not be distant when no vehicle in the public service shall be suffered to convey a person afflicted with any serious disease.

**A NEW FOOD.**—Mr. J. Hullett offers, through the medium of the *Times*, a few grains of the seeds of the true Chinese sugar-grass (*Sorghum Tartaricum*) to any one sending him a stamped envelope. It is a hardy cereal, and said to produce much more per acre than wheat, while the leaves furnish a valuable food for cattle. As some of our readers may be desirous of trying the cultivation of a new serial, we shall be only serving the liberal purpose of Mr. J. Hullett by adding his address, which is Clarence-lodge, Cosham, Hants.

**ST. THOMAS.**—The mail steamer *Seine*, which arrived last week, was detained at Southampton on account of some cases of yellow fever having occurred during the voyage, one of which had been fatal. This is not nearly so bad as the cases on which we have already quoted. The *Seine* brought an account of quarantine at Christmas which was of some interest, and her latest news speaks of the disease as rapidly disappearing. The total deaths had been 805 up to the 12th ult., on which day the *St. Thomas Tidende* thus writes:—

"The deaths from the malady by which we have been suffering have so considerably moderated within the last three days that we really think no one can hesitate to pronounce the disease as having ceased to be epidemic, and we should not be surprised that in a few days the authorities and the Board of Health would officially announce the disease to have ceased, with the exception of a few occasional paradics cases."

**BI-CENTENARY OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—The first Charter of this College was granted by King Charles II. on the 8th of August, 1667. Consequently the bi-centenary of that event will fall on the 8th of August in the present year, and will probably occur about the time when the British Medical Association will be in Dublin.—(See Belcher's Memoir of Dr. Stearne, Founder of the College.)

**CHANGE OF THE MODE OF MEDICAL EXAMINATION.**—We understand that the King and Queen's College of Physicians in Ireland have resolved that at the quarterly class examination to be held in February, and at all future class examinations, the examiners shall each give a printed paper containing five questions, and also a *viva voce* examination of five rounds. This, in fact amounts to closely following the M.B. Examination at Dublin University.

**LADY DOCTORS.**—The example set by Miss Garrett is not without effect. Last week three ladies passed the Preliminary Examination in Arts at the Apothecaries' Hall, London, and will, we presume, now go through the curriculum required by that body. If we are to have regularly-educated female practitioners, we cannot regret that the Society of Apothecaries should be the Corporation to grant the licence, for there is no other which has striven more continuously to raise the status of the profession, nor in which we could place more confidence, as likely to act with impartiality in carrying out this attempt.

**SMALL-POX IN LONDON.**—Since 1862 this disease has been on the increase in London, and at the present moment an epidemic is prevailing which may well excite alarm. This is well seen in the statistics of the Small-Pox Hospital, of which the annual meeting was held last Friday. In 1863 no less than 1537 cases were admitted. In 1864 the number fell to 836, to rise the following year to 1249, and last year to 2069. This is the largest number admitted in any year since the opening of the hospital 120 years ago. Nothing can be more conclusive as to the inefficiency of the Vaccination Act, as at present carried out. Amongst the unvaccinated the mortality in the hospital was nearly 40 per cent., while in the vaccinated it was less than 7 per cent. Such facts cannot be too frequently repeated.

**MORTALITY OF SCOTLAND IN THE COLD WEATHER.**—The mean temperature in the week ending January 26, in each of the eight towns of Scotland which furnish returns to the Registrar-General was:—In Glasgow, 34°6'; Edinburgh, 33°6'; Dundee, 33°4'; Aberdeen, 33°0'; Paisley, 33°0'; Greenock, 34°5'; Leith, 36°1'; Perth, 32°1'. In the corresponding week of the year 1866 the weather in the same places is said to have been "as mild as if it had been spring—the prevailing winds been west and south-west." The differences in the mortality of the week in 1866 and 1867 are seen in the following official returns. Deaths in the two weeks:—In Glasgow, 359 and 204; Edinburgh, 107 and 93; Dundee, 70 and 49; Aberdeen, 46 and 46; Paisley, 48 and 28; Greenock, 32 and 38; Leith, 22 and 15; Perth, 21 and 11. Totals—705 and 514. The lowest temperature recorded at Paisley in the late frost was 15°2'. The highest 49°8' at Glasgow. The range of temperature in the week was 29°8' in Paisley, and 31°6' in Glasgow.

RESIDENCES OF THE LONDON POOR.—This is a subject which has of late excited a great deal of attention. The altered condition of the city in consequence of requirements for mercantile and trade purposes, railroad extension, and improvements of various kinds, has driven large numbers to the suburbs, where they are thickly huddled together, in dwellings unfit for human occupation, both as it regards health and convenience of the lowest order. The investigation, though far from complete, of the Commons Select Committee of last session on the Local Government of the Metropolis, discloses a series of facts connected with the habitations of the poor which we shall endeavour to classify and present to our readers. In the district of Whitechapel, a member of the Board of Works states, that there are "5000 houses in courts, alleys, and small streets, which require to be constantly inspected in consequence of the disregard to cleanliness among the inhabitants, and if the places are made decent they are soon again found in a most filthy state. How far degraded habits may have been produced by the miserable abodes they have been compelled to live in it is difficult to say. The Medical Officer of Newington seems to think that these things have a reciprocal bearing, and that, as a rule, the better the residence the cleaner and more decent the tenant; and it is a fact, that if the lower classes of Whitechapel are perseveringly dirty, their houses in great part are unfit for human dwellings, without proper ventilation, built back to back against a dead wall or towering warehouse, situate in courts with no thoroughfare not above three yards wide. In the parish of St. George's, Southwark, the same state of things is found. The Vestry Clerk says:—"Many of the houses in this parish are so built as to be unfit for habitation, and many of the courts are such, that they would be injurious to life, whether over-crowded or not." And again, "there is no room in the yard for a dust-bin, and the people throw the refuse into the street for the scavengers to take away." A vestry man of St. Pancras speaks of houses there built in such narrow courts and passages, that they never could be wholesome habitations, and he considers that it would be for the public good to take them down. In some neighbourhoods a huge nuisance exists. In a confined district in St. George's in the East there is large dust yard, and if an order is obtained for the removal of the dust a mass of seven or eight hundred tons cannot be cleared off at once, and there it lies in hot weather, fermenting, offensive, and dangerous, day after day. In others there are objectionable manufactures which it is almost impossible to get rid of, all interfering more or less with the salubrity of the humble dwellings around. Who can wonder in such a state of things that disease and death should commit their ravages among those unhappy beings who are driven there for shelter. Who can wonder at fevers and epidemics of different kinds in such localities as these, and the insufficiency of every effort to counteract the infection. On fever breaking out at Rotherhithe, the clerk of the local board tried the only remedy open to him—viz., closing the houses; but before he could get the order from the magistrates, the fever spread through the district, and the curate and a relieving officer fell victims to it. We have confined ourselves to the places visited by the Commons Committee, though it is well-known that the evil exists more or less all round London. The longer it is neglected the more it will increase, and the difficulties of remedying it increase as well. What then will the metropolis do? Efforts are made in every direction to lessen the calamities which are

occurring around us. The city has never been backward in generous acts, or devising means of improvement, and we entertain the hope that it will ere long turn its attention to this gigantic evil.

VIVISECTIONS IN FRANCE.—A very temperate letter on this subject appears in the *Times* from the pen of Dr. Markham, who, since his recent appointment, has resigned the editorship of the *British Medical Journal*, which he for some time conducted with great ability, and the gentlemanly tone of which, whilst editor, he consistently maintained. The letter just mentioned is just such as might have been expected from Dr. Markham. It deprecates the use of immoderate language in any communications that may be made from this country as only likely to frustrate the very end proposed, and points out the objectionable manner in which on a former occasion the London Society proceeded to denounce the practice. The following paragraphs from Dr. Markham's letter are well worth attention:—

"One point, however, in the report is, as a caution in future proceedings, worthy of especial notice. I am sure you will agree that moderation in language should be carefully practised by those who attack these doings. That our French *confrères' susceptibilité*, was deeply wounded by the terms used in the documents above referred to as laid before them is manifest in their report. The committee of the Academy there very naturally object to phrases like the following cast at them:—'Inhuman and revolting practices,' 'outrages upon nature and upon God,' 'violation of all Christian principles.' 'We are told' (runs the report) that 'experimenters wear the hypocritical mask of science as an excuse for their atrocities; that they prolong vivisections to satisfy their infamous pleasures; that they practise infernal brutalities, which should be held up to the execration of the whole world,' &c.

"We can hardly hope to bring the Academy into a happy frame of mind for calm discussion by introducing the subject to their notice after this fashion.

"If, therefore, we again appeal to that learned body, let us address them in rational and scientific language, and not allow the negotiations to be marred by sentimental amenities of the above description.

"It is certain that the injudicious attacks hitherto made against French veterinary practices have injured instead of advancing the cause of humanity."

#### DEPUTATION OF THE HARVEIAN SOCIETY ON INFANTICIDE.

On the afternoon of Tuesday, the 29th ult., Mr. Walpole, Secretary of State for the Home Department, received an influential deputation of the Harveian Society, which was desirous of urging upon Government the necessity of some Legislative interference on this painful subject.

Dr. Tyler Smith said, the deputation from the Harveian Society sought to obtain a diminution of infantile mortality. A committee had been formed by the Society, and had resolved upon a series of recommendations for the consideration of the Government. The committee were of opinion that the following were the main causes of illegitimacy, and indirectly of infanticide:—1. The overcrowding of the dwellings of the labouring classes in urban and rural districts; 2. The custom prevailing in the North and West of England, and in Scotland, of public hiring of servants; 3. The gang system of agriculture; 4. The promiscuous lodging of the sexes during hop-picking, harvests, cider-making, &c.

Dr. Drysdale read the recommendations referred to.

Dr. Smith explained that their proposal was that the registration of all births should be compulsory, believing it would

greatly lessen the facilities of infanticide if a registration of still-births could be demanded. Then they considered the temptation to infanticide would be diminished by taking the chief of the burden of maintaining the child, and by dividing it between the father and the mother; for at present, in the case of an illegitimate child, the great burden fell upon the mother, and the person really sacrificed was the child. Next they proposed that the crime of infanticide should no longer be punishable by death, but that the recommendation of the Royal Commission on Capital Punishment be adopted, and that the offence be considered as murder in the second degree. This mitigation of capital punishment would seem to make the law less severe; but the wish of the Society was really to make it more severe, and with the difficulties which juries now experienced in convicting a mother on this charge they believed that if the punishment was made less it would reach the mother much more certainly and frequently. Further, they proposed to give the child the protection of the poor-law. Instead of leaving it to the mother to obtain assistance at the hands of the law from the father, they wished to give the poor-law the onus of reaching the father, who often escapes from the want of means on the part of the mother to support her case. The committee considered the maximum sum which may be assessed on the father of an illegitimate child should be raised from 2s. 6d. to 5s. a-week. They had also devised a system for the registration of nurses. At the present time nurses taking illegitimate children were so incompetent that it was rare for such children to reach maturity. The mortality of illegitimate children reached 70 to 75 per cent. The committee believed this might be diminished by providing penalties against any taking illegitimate children to nurse who are not duly registered; by restricting the charge of more than two children by one nurse; in short, to keep up an efficient registration and medical supervision of all wet-nurses and dry-nurses. The Society had recommended the prohibiting of children being congregated together, because it was seen that in that case they never thrive, and they would be better taken care of if distributed among a number of persons.

Mr. Walpole—Legitimate as well as illegitimate?

Dr. Smith—Yes.

Mr. Walpole—What do you attribute that to?

Dr. Smith replied, to various causes—to more care being taken of them, better ventilation, and then diseases of children were so many of them contagious.

Mr. Walpole—Do you recommend the alteration of the law in both cases?

Dr. Smith said not. The business of the committee was more with the illegitimate than the legitimate. Besides, the mortality among legitimate children was not so large as among the illegitimate. The committee also laid stress upon giving the mother the power to remain with her child in the workhouse during the four months after confinement; for it was proved that nothing could compensate for maternal care during the first few months of infancy. They wished to give her power, after the four months, to leave the child in the workhouse, the guardians having the power to recover from the mother a portion only of the sum required for its maintenance. They, moreover, suggested that for the rearing of children left in charge of the guardians a colonizing system should be adopted similar to that pursued by the Foundling Hospital and to that followed under the old poor-law system. In conclusion, Dr. Smith said the committee hoped some of their conclusions would be expressed in legislation. It was their belief that public morality would be thus improved; that crime would be prevented and punished; and that a saving of infant life would take place, especially of illegitimate infant life.

Dr. Pollock observed that the committee proposed that there should be such a system of surveillance over mothers of illegitimate children as to diminish their temptation to infanticide.

Mr. Brendon Curgenvin remarked that the mortality of legitimate children averaged from 24 to 30 per cent. as against 70 to 75 per cent. illegitimate. There were certain districts—such as Paddington—where the mortality was

even greater. With regard to the suggestion of the committee, that the establishment of foundling hospitals for the free and indiscriminate admission of infants would be attended by bad results, he stated that statistics showed that out of 14,000 admitted to six foundling hospitals, 1000 died. That was owing to the children being taken away so soon as three or four weeks from the mother.

The Home Secretary, having listened to the remarks the deputation had to offer, said the only thing he need say now with regard to any legislation on the subject brought before him was that a Bill, based upon the recommendations of the Capital Punishment Commissioners, would be introduced in the forthcoming session of Parliament. He could promise the deputation no more legislation beyond that without giving the subject much more consideration; but he should be obliged by any statistics with which the committee could furnish him.

Dr. Smith assured the right hon. gentleman the committee would provide him ample statistics on the subject, and, having thanked Mr. Walpole for his patient attention, the deputation withdrew.

#### REPORT OF THE DISEASES PREVENTION COMMITTEE OF THE CITY OF LONDON UNION.

FROM the final report of the Diseases Prevention Committee of the City of London Union, we learn that 1547 cases of diarrhoea, and 23 cases of cholera, occurred during the weeks ended from July 28th to December 15th—the number of deaths from cholera being 28, and those from choleraic diarrhoea 19. The daily returns were sent to Dr. Sedgwick Saunders, under whose superintendence the house-to-house visitation was carried on.

Dr. Sedgwick Saunders has presented to the Committee and to the Board of Guardians of the City Union, his report on the late epidemic of cholera, which has just been printed. It commences by saying that the experience of the Medical Officers employed in the Union has confirmed

“The conviction that the early treatment of diarrhoea cannot be too strongly insisted upon, as there is much reason to believe that this so-called *disease* is often an early *symptom* only, and must be looked upon as an essential premonition of the choleraic incidence; so that many cases treated successfully as diarrhoea ought, nosologically, to be classed under the head of cholera cured in its early or premonitory stage. This admits of no more direct *proof* than any other negative proposition; but analogy and experience justify the assumption—hence the advantage of searching out such cases by daily house-to-house visitation, and in this manner enabling the medical practitioner (by dealing with the disease at its inception) to arrest its degeneration into the more severe and less tractable phases.”

It is found that the percentage of fatal cases was considerably higher than at the London Hospital or the Cholera Hospitals, on which Dr. Saunders remarks:—

“I attribute this to two causes—first, and chiefly, to the *culpable disregard of ordinary and well-established sanitary precautions* on the part of the Commissioners of Sewers in the neighbourhood in which the cases originated (as abundantly proved by the reports of your medical visitors in the published returns of their house-to-house visitation). And secondly, to the fact that your medical officers have carefully excluded from their returns all cases in which the characteristic symptoms of *true Asiatic cholera* were wanting; whereas in some of the published returns there is much reason to believe that fatal cases of choleraic diarrhoea have been registered as deaths from *cholera*.”

Dr. Saunders considers that whether cholera be due to a poison in the air or water “it ought never to become epidemic.” He examines both the water and the air theories evidently leaning to the former; and he expresses

a fear that we must abandon the hope of rendering impure water fit for drinking by any of the common processes of filtration through charcoal, boiling, or the use of Condyl's fluid.

In connection with this subject, Dr. Saunders observes :—

"Another aspect of this very significant subject presents itself in connection with the question of the adulteration of milk. It is known that upwards of six millions of gallons of milk are sent into the metropolis from the country in the course of a year; and this quantity is ever on the increase. Now it is familiar knowledge to all, that this so-called milk is largely diluted by the dairy farmers, before reaching its urban destination; and the occasional use of a lactometer will convince the most sceptical of the enormous extent to which, by the fraudulent practices of the dairy-men, water is added to make up the bulk required. The water so used must, from the very nature of things, be drawn from wells supplied chiefly by the surface drainage of country districts where manure heaps and cesspools abound; and it requires no stretch of imagination to understand that, by this means alone, various diseases of the zymotic class may be conveyed from one locality to another. If we cannot get pure milk, the farmers should be at least taught that the sophistication which they now practise with impunity should not be the means of converting a commercial fraud into a sanitary crime.

"The only reliable and permanent remedy against the evils of retaining water for domestic purposes in improperly constructed, exposed, or filthily kept receptacles, will be the institution of the *constant* in place of the present *intermittent* service; and until this is accomplished, we shall have frequent reason to complain of the injurious effects of retention upon the quality of the water so stored.

"In our recent house-to-house inspection, we found this to be almost universally the case; the water was received into cisterns or water-butts, placed too often over common privies, or in other equally objectionable situations which afford a ready access to the noxious exhalation from neighbouring untrapped drains, dust heaps, &c., and for which there appears no other remedy than the "*constant*" supply. To obtain this inestimable boon, every opportunity should be taken to instruct the public upon the subject, in order that the necessary outlay may be submitted to. It is manifestly unfair to rail against the Water Companies for their endeavours to economize the commodity in which they deal, so long as the present indifference as to the commercial value of pure water (leading to a wasteful expenditure of the same) continues. At present, the daily issue for the whole of London is at the rate of thirty gallons per head of the entire population, whereas it is computed that one-third of that quantity might be saved if well-known mechanical appliances were adopted by which the amount used by each consumer could be accurately measured, like our gas, and paid for accordingly."

Dr. Saunders strongly advocates the employment of Medical Men as Sanitary Inspectors. He would have each District Medical Officer of the City Unions appointed Assistant Officer of Health, and we believe his plan to be both feasible and desirable. The Commissioners of Sewers have appointed four additional Inspectors, but, observes Dr. Saunders, with not unmerited severity :—

"I regret to report that these Inspectors have been so entirely unfit for such appointments; and I can anticipate nothing but a repetition of disastrous oversights, against which I have previously had occasion to inveigh, so long as the Commissioners of Sewers persistently reject a proposal long since made to them by competent persons, chosen from the same class of men who have heretofore proved and recently impressed upon them by a member of their own body: that these inspectorships should be conferred upon properly qualified medical men, who alone are capable of estimating the sanitary requirements of the several districts in which they are daily working. The remedy is so

simple and facile of accomplishment, that every well-wisher of our great city must regret to find a body of men individually sensible and practical, assuming in their collective capacity an infallibility of action, and treating with supercilious disdain any suggestion originating from without the circle of their corporate existence."

There are many other interesting points discussed with ability in the reports which we have thus analysed, but to which we have not space to refer. We quote the concluding paragraph of Dr. Saunders, on account of its containing a warning we have more than once expressed :—

"In conclusion, I desire to express my earnest conviction, founded upon a diligent examination into the history of previous epidemics, that the cholera has not yet left this country; and, judging from the erratic course it has taken on the Continent, in Egypt, and elsewhere, I may almost venture to predict that it will become active again in the coming spring, if, indeed, it does not appear before. Week by week we may watch its presence still amongst us; and when we remember the numerous exciting causes still in existence and surrounding us (to our shame as a nation), that man must be bold indeed who would relax the smallest effort for its extinction."

### LONDON WATER SUPPLY.

WE find in the Registrar-General's report for last week an account of the quantity and quality of the water supplied to the inhabitants of London by the several water companies. Nine companies state that during the month of December they supplied an average quantity of a cubic metre, or nearly a ton of water *daily* to each house. Professor Frankland has furnished a careful analysis of the waters for the month of January with the following results :—

Companies.	Number of Houses supplied in December, 1866.	Average Daily Supply of Water in Gallons during the Month of December, 1866. (See Note.)	Solid Matter in 100,000 parts of the Waters.	Organic and other Volatile Matter included in Col. 4.	Amount of Oxygen required for oxidation of Organic Matter.	Total Hardness.
Thames.						
Chelsea	26,783	7,756,200	31.34	2.39	.0532	18.5
West Middlesex	36,331	7,872,706	31.99	2.33	.0532	18.8
Southwark and Vauxhall	73,940	13,130,500	32.42	2.56	.0532	18.8
Grand Junction	26,450	8,650,150	32.82	1.28	.0597	19.4
Lambeth	37,165	8,819,100	31.88	2.32	.0597	19.4
Other Sources.						
Kent	33,693	6,149,006*	39.40	1.22	.0223	22.5
New River	112,852	21,621,000	31.39	0.69	.0432	19.4
East London	90,174	19,842,000	35.68	2.64	.0727	20.5
South Essex†	910	183,497	37.93	3.02	.0140	22.2

Note.—The water includes the supply for manufactures and for various purposes other than domestic consumption. Total number of houses supplied, 438,298; average daily supply of water in December, 1866, 94,054,159 gallons. This return, as compared with that for the previous month, shows an increase of 160 houses and a decrease of 1,002,995 gallons of watersupplied daily.

\* Erratum.—Return No. 51, 1866.—For 5,503,833 gallons, read 6,503,833 gallons.

† The secretary to the South Essex Waterworks Company, writing in October, 1866, states :—"We have not extended our mains at present west of Romford." In other words—not to London.

The table may be read thus :—100,000 lb. of Chelsea water contained 31.34 lb. of total impurity, of which 2.39 lb. were driven off by incineration; .0532 lb. of oxygen was required to oxidize the organic matter. Of the solid residue, 18.5 lb. were carbonate of lime, or its equivalent of hardening salts.

The fourth column of this table contains the amount of solid matter left on evaporation and desiccation at 120°—130° C. (248°—266° F.). The results are recorded in 100,000 parts. By moving the decimal point one place to the right the above figures express in milligrammes the quantities contained in one kilogram of the several waters.

The whole of the waters, with the exception of the New River Company's, were slightly turbid when drawn from the companies' mains; the Kent and South Essex Companies' waters contained in suspension a quantity of white flocculi.

## THE WEATHER AND THE PUBLIC HEALTH.

THE Registrar-General's returns for the week ending January 26th fully justify our prognostications in reference to the probable continued influence of cold upon the death-rate. We have to add 239 deaths in excess of the average to the 732 reported as killed by the cold in the previous fortnight. If we turn to the reports from the large towns we find in all that the mortality has been increased during the cold weather, the annual rate of mortality having risen to 35 per 1000 persons living.

So many important points are discussed in this week's returns that we transfer the following paragraphs to our columns:—

"The deaths registered in the last three weeks ending the 26th of January amounted to 5495, while the deaths of the three preceding weeks ending the 5th of January amounted to 4250; and the difference is 1235. Now, the mean temperature of the three cold weeks ending 29th of December, 42°9'; leaving a difference of 12°7'.<sup>a</sup> So every the 19th of January was 30°2'; of the three mild weeks ending the degree of depression over three weeks corresponded nearly to 100 deaths in London. The excessive number of deaths is thus distributed over five ages—164 at ages under 20, 123 at 20-40, 312 at 40-60, 531 at 60-80, and 105 at the age of 80 and upwards. When the deaths are compared with the numbers living at the corresponding ages, these results are obtained—100,000, persons living at each of the five ages the deaths were 12 at 0-20, 12 at 20-40, 56 at 40-60, 297 at 60-80, and 888 at the age of 80 and upwards. As age advances after childhood, the power fails of producing the internal warmth by which life is upheld. So while youth and vigour enjoy the frost, age and feebleness perish.

"The annual rate of mortality last week was 32 per 1000 in London, 32 in Edinburgh, and 43 in Dublin; 35 in Bristol, 28 in Birmingham, 41 in Liverpool, 48 in Manchester, 40 in Salford, 31 in Sheffield, 29 in Leeds, 30 in Hull, 43 in Newcastle-upon-Tyne, and 42 in Glasgow. The rate in Vienna was 30 per 1000 during the week ending the 19th inst. when the mean temperature was 61° Fahrenheit higher than in the same week in London, where the rate was 29 per 1000.

"At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29°652 in. The barometrical reading increased from 29°31 in. on Thursday to 29°97 in. on Saturday. The mean temperature of the air in the week was 37°2, which is 0°5° below the average of the same week in 50 years (as determined by Mr. Glaisher). The highest day temperature was 54°5° on Thursday. The lowest night temperature was 22°0° on Tuesday. The entire range of temperature in the week was, therefore, 32°5'. The three first days of the week were extremely cold, the three last mild. The mean of the highest temperatures of the water of the Thames was 32°8'; that of the lowest was 30°8'. The difference between the mean dew-point temperature and air temperature was 4°8'. The mean degree of humidity of the air was 82, complete saturation being represented by 100. The direction of the wind was variable. Rain fell to the amount of 0°35 in. On Tuesday at 7°30 P.M., the temperature then being 23°, a remarkable shower of rain commenced to fall, and the drops as they were deposited on the surface were instantly frozen. The temperature then began to increase; by 9 P.M. it was 25°, by 10 P.M. 30°, and by midnight 33°. Throughout the whole of this time occasional showers were noticed, and the surfaces on which the rain fell became thickly coated with ice. After midnight a very rapid thaw began. According to a return furnished by the engineer of the Metropolitan Board of Works, the average daily quantity of sewage pumped into the river Thames at the Southern Outfall Works, Crossness, was 57,865,859 gallons, or 262,909 cubic metres, equivalent to about as many tons by weight."<sup>†</sup>

## Correspondence.

## HEALTH RESORTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having seen in the last number of your valuable journal the review of a book on the climate and position of one of our English towns on the southern coast, I thought possibly a few remarks on those health resorts of the Mediterranean, to which so many, now-a-days, are crowding as the year draws to a close, might, perhaps, not be out of place in your columns. I beg leave, therefore, to send you a few facts derived from personal knowledge and observation while sojourning in various places in search of the inestimable blessing of health. Some years ago I was recommended, and strongly urged, by my medical attendant to pass the winter in the South of France. I took his advice, and followed it out for several successive winters, spending them at different places along the Riviera, between

Marseilles and Genoa. I am free to confess that the climate there at that season of the year is different from ours in England, not liable to such sudden changes, and is generally fine and beautiful through December and part of January. But after that in February and March the mistral sets in, a strong and cutting wind which is terribly felt in all places where the mountains recede any distance from the shore. Then the mornings and evenings are cold, and the contrast from the warm mid-day sun is so great that it frequently produces most injurious effects on the invalid.

There are occasional storms too—lightning and thunder, and drenching rain, which pouring down from the mountains fills the streams and rushes on to the sea, discolouring it with white mud for miles away. At such times as these it is necessary to keep as closely to the house as in the worst phases of the English climate.

One of the greatest annoyances to be complained of is the dust. It lies everywhere, in all directions, and when the wind is high it is driven for miles along the roads, and may be seen rising in clouds over the tops of the loftiest houses. Or if the air is calm and the day inviting, and you think of having a lovely invigorating ride, the wheels of voiture and the tramping feet of the horses do what the wind did before: surround you with a cloud of dust which annoys you beyond measure. Besides this, all the towns are badly drained, and sometimes the smells are intolerable. These are some of the disadvantages attending a winter's residence there in the most favourable seasons, but there are years when the propriety of going at all is very equivocal. The cold is sometimes very severe, and the season unpropitious. I have known the ice thick enough to bear, and seen the gentlemen who were staying at the same hotel as myself out sliding upon it, and longing for some skates to astonish the natives while amusing themselves; and the same season the snow and sleet fell, and the winds blew fearfully cold down to the sea shore. Many winters at home have been scarcely less unfavourable than that. This year, also, I find from others that snow, frost, and cold winds, have been prevalent there. The following quotation from the *Daily Telegraph* shows that my information is correct:—

"Montone, generally a sort of human hothouse, has been drenched with cold rains and lashed by the mistral; so have Cannes, Nice, and Hyères; while the same snowstorms which twice covered this kingdom with a white veil also hid France from end to end in wreaths and drifts. The trains have stuck fast with the Frenchmen as well as with ourselves. Far south even—at Bremen, Nismes, Grenoble, Avignon—nothing could move for days on the line; and on the country roads traffic was quite suspended. The railroads, almost from end to end of France, were lined by huge walls of snow, whirled and piled in dazzling fantastic shapes along the cuttings and levels. Even among the olives and cypresses of Provence, where frost is hardly known, there have been deep snow-drifts, and the hot volcanic hills round Marseilles have been whitened from head to foot with snow."

It is natural for persons when ill, especially those whose lungs are tender, who feel the effects of this changeable atmosphere, to think that a sojourn during the winter months in a more equable climate will be an effectual means of restoration to health. It may be that in certain cases many have found relief, and some few restoration. Yet I have known persons who have gone out under medical direction, and who had every appearance of deriving benefit from the change, fall away and die in a season or two, contrary to their own expectation, and the earnest hopes of their friends. The first time I entered the burying ground connected with the English Church at Nice, I was forcibly struck with the extent to which this occurs. The enclosure is filled with the dead who came out eager to regain their health, but whom the last enemy ruthlessly pursued and overtook, and the various tomb-stones, the last indication of surviving and sorrowing affection, silently reiterate the melancholy tale.

On the whole I give it as my opinion, judging from experience, that if the people would make up their minds to stay at home, keep their houses warm and dry, and not go out in bad and treacherous weather, they would be quite as well in their own native country. The money which they spend among foreigners would be more than amply sufficient to surround themselves with every comfort and every luxury they might require, as well as to encourage trade and give employment to many a poor destitute family at home. But it is fashionable to go away for the winter, and pride often makes excuses about health the more easily to justify the expenditure and excess. It would be well if this fashionable mania, which invariably

<sup>a</sup> To allow for the interval between the dates of death and registration, and to some extent for the time between the first application of cold and its effects, the deaths registered in each week are compared with the temperatures of the week before.

<sup>†</sup> A cubic metre is equal in volume to 35°3174 cubic feet, or to 220°0967 imperial gallons. It is nearly equivalent to the old English tun of four hogsheds, holding 35°248 cubic feet. It is in general use on the Continent, and is a much better unit for measuring sewage or water supply than the gallon.

engenders a restless spirit, satisfied with nothing, and contented nowhere, could be put an end to. People would then find out that they are as safe by their own fire-side as elsewhere, and that they are able to enjoy the comforts which no other country can afford; and then when summer returns they can visit our own beautiful and healthful watering-places, and feel themselves refreshed by the change.

In fact, if so disposed, there are several nicely sheltered places in England where they might very advantageously and safely pass the winter months without the fatigue, and in many respects inconvenience, of going abroad. Hoping you will see the justice of my remarks, I am, sir, your obedient servant,  
ONE WHO HAS CEASED TO BE A WANDERER.

### VIVISECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I, for one, cannot forbear expressing my utter abhorrence of the abominable cruelty practised in France in the absolutely unnecessary practice of vivisection.

Since the discovery of the circulation of the blood, and the investigations of Sir Charles Bell, Majendie, and others, I think it will be freely admitted by all humane and sensible men that there is no real occasion whatever to subject the poor helpless brutes to such inhuman tortures as those to which *Veterinarian* alludes at page 69 of your valuable journal of the 16th ult.

I denounce the practice, therefore, as unjustifiable cruelty, and must attribute its continuance to a morbid desire to indulge in wanton cruelty under sanction of law. The merciful man is merciful to his beast, and mercy and kindness are indispensable qualifications to those who would be surgeons in a right point of view. I would strongly advise those young men who think they are aspiring to fame, to devise better means in furtherance of their object than that of verifying the assertion that "the tender mercies of the wicked are cruel."—I am, sir, yours, &c.,  
CLEMENS.

### NAVAL ASSISTANT SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is to be hoped that the Dublin Medical Students will not be behind their London brethren in declaring their opinion of the late proposition of the Admiralty, and in supporting the honour of the profession they aspire to, by not qualifying with a view to enter the navy until the position of the medical branch of that service is much improved, and its members treated with fit consideration, least, perchance, some truth might attach to an expression recently made use of in the public press—that the services were supplied by "the sweepings of the Irish schools."—I am, sir, your obedient servant,  
AN IRISHMAN.

### MEDICAL ACTS AMENDMENT BILL.

The following is the Draft of a Bill to Amend the Acts relating to Practitioners in Medicine and Surgery:—

Whereas the Medical Act (1858) has been found ineffectual to enable persons requiring medical aid to ascertain who are qualified practitioners, and it is desirable to amend the said Act in several respects.

Be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of same, as follows:

#### PRELIMINARY.

I. *Construction and short titles.*—The Acts described in the Schedule to this Act and this Act shall be construed together as one Act; and for that purpose the expression "this Act," when used in the Medical Act (of the session of 1858), shall include the present Act; and the Acts described in the Schedule to this Act and this Act may be cited together as "the Medical Acts," and be comprised in that expression when hereafter used in this Act; and this Act may be cited separately as "The Medical Acts Amendment Act (1866)."

#### MEMBERS OF COUNCIL.

II. *Amendment of Sect. 7 of Act of 1858.*—Section 7 of the Medical Act (1858) shall be read and have effect as if the words "qualified to be" were omitted therefrom.

#### REGISTRATION.

III. *Erasure by Order of Council.*—Where, under the authority of the Medical Acts, the General Council, or any Branch Council, direct the erasure of the name of any person from any Register, the name of that person shall not be again registered in any Register except by direction of the Council which directed the erasure, or by order of a Court of competent jurisdiction.

IV. *Restoration of name.*—If the Council think fit in any case, they may direct any Registrar to restore to his Register any name erased by him therefrom, and the Registrar shall restore the same accordingly.

V. *Repeal of Sect. 14 of Act of 1858.*—Section 14 of the Medical Act (1858) is hereby repealed; but this repeal shall not affect the past operation of that section, or anything already done under it, or invalidate any existing Register, order, or regulation kept or made under it, or affect any proceeding or thing commenced under it, or the power of the General Council to make any order in relation thereto; and every such proceeding or thing may be carried on and done as if the said section had not been repealed.

VI. *Registers to be corrected.*—Each Registrar shall keep his Register correct in accordance with the provisions of the Medical Acts and the general regulations and special directions of the General Council (whether made or given before or after the passing of this Act).

VII. *Erasure on death.*—Each Registrar shall erase from his Register the name of any person deceased.

VIII. *Alteration of address, &c.*—Each Registrar shall from time to time insert in his Register any alteration in the address or qualification of any person registered.

IX. *Evidence of death, &c.*—In the execution of the aforesaid duties, each Registrar shall act on such evidence as in each case appears to him sufficient, subject to any regulations of the General Council.

X. *Erasure on ceasing to practise.*—Each Registrar may erase from his Register the name of any person who, having ceased to practise, shall desire to have his name removed from the Register; and each Registrar may send by post to any person registered in his Register a registered letter, addressed to that person according to his registered address, inquiring whether or not he has ceased to practise, and whether he desires his name to be retained on the Register. And if the Registrar does not, within three months after sending such a letter, receive any answer thereto from the person to whom it is sent, he may within fourteen days after the expiration of the said period of three months, send by post to that person another registered letter, addressed to him according to his registered address, referring to the first letter, and stating that any answer thereto has not been received by the Registrar; and if the Registrar does not within three months after sending such second letter receive any answer thereto from the person to whom it is sent, that person shall, for the purpose of the present section, be deemed to have ceased to practise, and not desire to have his name retained on the Register. And the name of any person shall not (without his consent) be removed from the Register on the ground of his having ceased to practise, except in pursuance of the provisions of the present section. Provided that a person whose name has been erased from the Register with his consent, on the ground of his having ceased to practise, shall not be liable to any penalty under this section by reason of his being engaged gratuitously in the cure or treatment of any disease or injury.

XI. *Registration of Foreign and Colonial Practitioners.*—Every person who has resided in the United Kingdom for a period of not less than twelve months immediately previous to making his application, and who legally possesses a colonial or foreign diploma from a University, College, or other body qualifying him to practise medicine or surgery in the colony or foreign country where such diploma was obtained, shall be entitled to be registered under the Medical Act (1858). Provided such diploma shall have been granted by a University, College, or other body recognized in a list to be annually prepared by the General Medical Council, which list shall be submitted to Her Majesty in Council for approval, and shall thereupon be published in the *London Gazette*.

XII. *Privy Council may add to list of qualifications.*—If it appear to the Privy Council, on representation by the General Medical Council, that any qualification, other than those described in Schedule (A) to the Medical Act (1858), as amended by this or any other of the Medical Acts, is granted by any University, College, or body in the United Kingdom, legally entitled to grant the same, after such a course of study and such examination as guarantee to the satisfaction of the General Medical Council that any person to whom such qualification has been granted possesses the requisite skill and knowledge for the efficient practice of medicine or surgery, it shall be lawful for Her Majesty in Council to direct by order that every person holding such qualification shall be entitled to be registered under the Medical Act (1858), in the same manner and with the like effect as if the qualification were inserted in the Schedule (A) to the Medical Act (1858).

XIII. *Application of Provisions 20, 21, 22, 29, and 39 of the Medical Act of 1858.*—The provisions contained in Sections 20, 21, 22, 29, and 39 of the Medical Act (1858) shall apply to any qualification which in pursuance of this Act entitles persons to be registered under the Medical Act (1858).

XIV. *Degree of Bachelor of Surgery to be a qualification.*—The degree of Bachelor of Surgery conferred by any University in the United Kingdom, which now is, or hereafter shall be, legally entitled to confer the same, shall, for the purpose of enabling any person to be registered under the Medical Act (1858), be deemed to be one of the qualifications described in Schedule (A) of that Act.

#### UNREGISTERED PERSONS.

XV. *Repeal of Sect. 40 of Act of 1858.*—Section 40 of the Medical Act (1858) is hereby repealed; but this repeal shall not apply to or in respect of any offence committed before the passing of this Act, or affect any proceeding pending at the passing of this Act.

XVI. *Penalty for the assumption of titles, &c., by unregistered persons practising medicine or surgery.*—If any person practising medicine or surgery, or engaged in the cure or treatment of diseases or injuries, not being registered under the Medical Acts, takes or uses any of the designations enumerated in Schedule (A) to the Medical Act (1858), as amended by this Act, or by any other of the Medical Acts, or the designation of Physician, Surgeon, Doctor, or Apothecary, or any other designation used by or used to distinguish duly qualified practitioners of medicine or surgery, or any class thereof, or the designation of Professor of Medicine or of Professor of Surgery, he shall for every such offence be liable on summary conviction to a penalty not exceeding twenty pounds.

#### SAVING.

XVII. *Extension of savings to former Acts.*—Nothing in this Act shall prejudicially affect any occupation, trade, or business, rights, privileges, or employment expressly saved from the operation of the Medical Act (1858), or affect the rights or interests of any person or class of persons expressly exempted or protected by any provision of any of the Acts described in the Schedule of this Act.

## Medical News.

**APOTHECARIES' HALL OF LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, January 31, 1867:—

William Draper, Middlesex Hospital, Grantham.  
Samuel Charlesworth Hirst, Leeds Hospital, Bowling, Bradford.  
William Edward Ditchett, London Hospital, Louth, Lincolnshire.  
Henry Edward Armstrong, Newcastle Hospital, The Dispensary, Newcastle-on-Tyne.  
Richard Strange Hall, Manchester Hospital, Leight, near Manchester.  
William Liffé, St. Bartholomew's Hospital, Nuneaton.  
Frederick Octavius Davies, St. Bartholomew's Hospital, Bermondsey, New Road.  
Charles Berrell, King's College Hospital, Arundel-street, Strand.  
Robert T. Jenkins, Charing-cross Hospital, Brewer-st., Oxford.

**LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL [IRELAND], for the month of January, 1867:—**

Cordner, Lonis Maxwell, Dublin, L.R.C.S.I. 1866; L. 1866, and L. Midwif. 1866, K.Q.C.P.I.  
Pearsall, Wm. Rooth, Dublin, L.R.C.S.I. 1866.  
Morgan, Jerome William, Rathgar, County Dublin, L.R.C.S.I. 1865; L.K.Q.C.P.I. 1866.  
Drew, James Blakney, Termonfeekin, County Louth, L.R.C.S.I., 1866.  
Power, Robert Vincent, Cork, M.D., Q.U.I. 1866; L. in Mid. R.C.S., Edin. 1866.  
O'Reilly, Thomas, Kilkenny, L., 1866, and L. Midwif. 1866; K.Q.C.P.I., L.R.C.S.I.  
Bolster, Thomas, Mallow, Co. Cork, L.R.C.P.I. 1866; L.R.S.P.I. 1866.  
Orton, Frederic, Beeston, Notts, M.D. Univ. Dub. 1866, L.R.C.S.I., 1865.  
Nason, Henry Wilson, Conna, County Waterford, L.R.C.Phys. Edin. 1866; L.R.C.Surg. Edin. 1866.  
Kerin, John, Tralee, County Kerry, L.R.C.S.I. 1865.  
Supple, James Francis, Dublin, L. 1866, and L. Midwif. 1866; K.Q.C.P.I., L.R.C.S.I. 1865.  
Holmes, T. J. Paul, Rathmines, County Dublin, L.R.C.S.I. 1866; M.B. Univ. Dub. 1866.  
Purcell, Geoffrey Chaucer, Dublin, L.R.C. Phys. Edin. 1867; L.R.C.S. Edin. 1867.  
Wheeler, William Ireland, Robertstown, County Kildare, L. 1866, and L. in Midwif. 1866; K.Q.C.P.I., L.R.C.S.I. 1866.  
Wade, Nugent, Killocock, County Kildare, L. 1866, and L. Midwif. 1866; K.Q.C.P.I., L.R.C.S.I. 1866.  
Irving, George Clerk, Dublin, L.R.C.S.I. 1866; L.K.Q.C.P.I. 1867; Townsend, Edmond, Cork, M.D. Q. Univ. Ireland, 1866; Mast. Surg. Q.U.I. 1866.  
Cogan, Thomas Sillery, Slane, County Meath, L.R.C.S.I. 1866; L. 1867, and L. Midwif. 1867, K.Q.C.P.I.  
Ternan, Obadiah, Dublin, L. Apoth. Hull, Dub. 1867.  
O'Reilly, James, Dublin, M.B. 1866, and Mast. Surg. 1866, Univ. Dublin.

THE Paris correspondent of a Belgian journal mentions that the Emperor fainted, the other day, on his return from a shooting excursion.

**CARBOLIC OR PHENIC ACID.**—This compound, recently found so efficient as a disinfectant, is now used for internal disinfection, in the form of a lozenge.

**EXCESSIVE COLD.**—Three inquests were held on the 17th ult., on persons who had died from the cold. They were—a boy named Johnson, a native of Barbadoes, who came over in the ship *Islander*, and two elderly women, named McDonald and O'Neil. The evidence in each case showed that the excessive cold was at least the proximate cause of death, and the juries found accordingly.

**MEETING OF THE MONAGHAN GUARDIANS.**—At a large and influential meeting of the Monaghan Board of Guardians, on the 30th ult.—the Right Hon. Edward Lucas, in the chair—on the motion of James Fiddes, Esq., Hollywood, seconded by Joseph Crowe Wright, Esq., J.P., it was unanimously resolved that the salary of Dr. Coulter, Medical Officer of the Scottstown Dispensary District, be increased from £80 to £100 per annum.

**THE WEATHER IN CORNWALL.**—The *Times* says that the readings of thermometers kept at Altarnum vicarage, Cornwall, prove that the approximate mean temperature of the first 22 days in the present month was (omitting decimals) 30°. The absolute *minimum* temperature was reached on the morning of the 15th, when the thermometer in the air registered 28° and on the grass 30° below the freezing point of water, a temperature very rarely attained in Cornwall. The

total rainfall of the 22 days amounted to 7.83 in. The wind during the same period traversed two complete circles, performing the first in six days without remaining long in any point of the compass. The weather is now very mild.

**PAUPERISM.**—The comparative statements respecting pauperism in England and Wales for the month of November, 1866, and the same month in the preceding year have just been issued. For the whole kingdom, the increase in the fourth week in November, 1866, as compared with the same week in 1865, was 17,742, or 2.1 per cent. The returns for five divisions—the South-Eastern, South Midland, North Midland, North-Western, and York—show a decrease. The greatest decrease is in the North-Western division, which comprises the two counties of Lancaster and Chester. There were 4642 fewer paupers in the fourth week of November, 1866, than in the same week in 1865. In the Northern division, which contains Durham, Northumberland, Cumberland, and Westmoreland, there had been as great an increase in proportion to population as there was a decrease in the cotton manufacturing districts. In the northern division the difference between the two months was only 4.9 per cent. increase. In the last week in November, 1866, the metropolitan unions relieved 16,572 more paupers than in the corresponding week in 1865. The difference between the two weeks was an increase of 16.9 per cent.

**THE LATE DR. M'CANN.**—This well-known member of the profession died on the 24th ult., of bronchitis. He was a remarkable example of the success which may be obtained by persevering industry, though it may not be accompanied by extraordinary abilities. Born in Ireland, he commenced his career in the metropolis as dispensing assistant to a firm of leading apothecaries, more than forty years ago. By his industry and assiduity he speedily obtained sufficient funds and intelligence to enable him to pass the College of Surgeons. This he did in 1827. He soon after established himself in practice in Parliament-street. By great tact and knowledge of the world he soon became the leading practitioner of the neighbourhood. He obtained several important posts. He was surgeon of the A division of Police, Surgeon to the Royal Humane Society, Justice of the Peace for Middlesex, and Deputy Lieutenant of two counties. His career is an example to others who, without friends or patronage, have to fight the battle of life.—*Lancet*.

**ARMY MORTALITY.**—The Provost Marshal-General of the Army of the United States has made his final report, showing the operation of his bureau from its organization, in March, 1863, to the close of the war. The tables annexed to the report show that 230,739 officers and men lost their lives in the army. Of this number 5221 commissioned officers and 90,886 enlisted men were killed in action or died of wounds, while 2321 commissioned officers and 182,329 enlisted men died of disease, or, in some few cases, of accident. This will give 1 officer killed in action or died of wounds to every 18 enlisted men, which makes the mortality of the officers somewhat greater than that of the men, as the former constitute about 1.25th of the entire force, supposing the organizations to be full. We find, however, on the other hand, that not 1 officer to 90 men has died of disease. Several reasons are given for this remarkable disproportion in favour of the commissioned class; one is, "the superior morale, the hopefulness and elasticity of spirit which is given to a man by investing him with a commission and its accompanying authority, responsibility, and chances of advancement." The disproportion between the mortality of the commissioned officers and enlisted men of coloured troops is still more noteworthy. In this branch of the service the officers lost in killed or died of wounds, 1 in about 42, while the men lost but about 1 in 66. The officers, however, show of deaths by disease a loss of only 1 in 77, while the men show the enormous proportion of nearly 1 in 7, which is by far the highest mortality from this cause exhibited in the records of the army. As the general proportion of deaths from disease among white troops is less than 1 in 17, the question comes up as to whether it is an economic or philanthropic measure to employ troops who are so eminently liable to death from diseases incident upon camp life. It is stated that the loss of the regular army from desertion was 244.25 per 1000, while in the volunteers it was but 62.51. This is accounted for on the ground that the men who enlisted in the regular army, a large proportion of whom were foreigners, were far inferior in character to those furnished by the States.—*New York Times*.

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Communications respecting Hospital Reports should be addressed to "Editor of Hospital Reports Department," London, Edinburgh, and Dublin, respectively.

*M.D.T.C.D.*—Will the correspondent who writes under this signature favour us with a title to his paper?

*The Harveian Society.*—The notice has been received.

*The Royal Institution.*—The notice has been received.

*Mr. Callender.*—The list is inserted.

*Mr. Richardson.*—Your letter has been received, and will appear in our next.

### MEDICAL VACANCIES.

Belgrave Hospital for Sick Children—Hon. Physician and Hon. Surgeon.

Holton Infirmary—House-Surgeon.

Cumberland Infirmary—House-Surgeon.

Western General Dispensary—Physician in Ordinary.

### MEDICAL APPOINTMENTS.

ARCHER, J., F.R.C.S.E., has been appointed Consulting Accoucheur to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for the Diseases of Women and Children, on resigning as Surgeon.

BAUMLER, C., M.R.C.P.L., has been appointed Honorary Assistant-Physician to the German Hospital, Dalston.

BELL, H. R., M.R.C.S.E., has been appointed Honorary Surgeon to the St. Pancras and Northern Dispensary, vice R. P. Middlemist, L.R.C.P.L., resigned.

DANE, T., M.R.C.S.E., has been appointed an Assistant-Surgeon to the Western Ophthalmic Hospital, Marylebone-road.

DWYER, HENRY, L.R.C.S.I., L.K.Q.C.P., L.M., has been elected Medical Officer to the Newport Dispensary District, Tipperary.

EDWARDS, G. N., M.D., F.R.C.P., has been appointed Physician to St. Bartholomew's Hospital, vice Dr. Jeaffrson, deceased.

EDWARDS, J. H., M.R.C.S.E., has been appointed Surgeon for the Home District of the Chorlton-on-Medlock, Rusholme, and Moss-side Dispensary, Manchester, vice J. Modd, M.D.

ELKINGTON, G., jun., M.R.C.S.E., has been elected Hon. Surgeon to the Birmingham General Dispensary, vice C. Warden, M.D., resigned.

FOSTER, M., M.D., has been appointed Teacher of Practical Physiology and Histology in University College, London.

GREALY, Dr. F., has been appointed Medical Officer for the Moycullen Dispensary District of the Galway Union, vice R. J. Morgan, L.R.C.P.Ed., resigned.

HALL, F., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for District No. 1 of the Leeds Township, vice Robert Cottam, M.R.C.S.E., deceased.

HUTCHER, Dr. W., late Physician and Medical Superintendent of the City Parochial Fever Hospital, Glasgow, has been appointed Assistant Medical Officer to Town's Hospital and Lunatic Asylum, Glasgow, vice J. B. Barbour, M.D., appointed Resident Medical Officer to the London Fever Hospital.

JONES, R. A., M.R.C.S.E., L.S.A., has been appointed Medical Officer to the North Wales Training College, Carnarvon, vice R. Jones, M.R.C.S.E., L.S.A., deceased.

LEE, H., F.R.C.S.E., Hon. Fellow of King's College, London, Surgeon to St. George's Hospital, has been appointed Surgeon to Queen Charlotte's Hospital, vice Chas. Hawkins, F.R.C.S.E., resigned.

LEWIS, F., M.R.C.S.E., has been appointed Assistant-Surgeon to the Western Ophthalmic Hospital, Marylebone-road.

MACBETH, J., M.A., M.B., C.M.Ed., has been appointed Senior Resident Surgeon to the Birmingham Lying-in Hospital and Dispensary for Diseases of Women and Children.

MASON, F., F.R.C.S. (formerly Assistant-Surgeon to King's College Hospital), has been elected Assistant-Surgeon to the Westminster Hospital, vice Christopher Heath, F.R.C.S., lately appointed to University College Hospital.

MOORE, J. D., M.D., F.L.S., has been appointed Honorary Medical Officer to the Lancaster Infirmary.

NESHAM, T. C., M.D., has been elected Physician-Accoucheur to the Lying-in Hospital, Newcastle-on-Tyne, vice S. M. Frost, M.D., resigned.

THOMPSON, W. A., M.R.C.S., L.M., L.S.A., has been appointed Surgeon and Accoucheur to the Oxford Medical Dispensary and Lying-in Charity.

WARD, T. M. M.R.C.S.E., L.S.A., has been appointed Admiralty Surgeon and Agent at Exmouth, vice Mr. Allan Waters, deceased.

WESTMORELAND, J., L.R.C.P., Ed. &c., has been appointed Resident Medical Officer to the New Bridge-street Workhouse, Manchester.

The Senate of the University of Glasgow at their meeting on Thursday, 24th January, conferred the degree of LL.D., on R. G. Mayne, M.D., of Leeds, author of the "Expository Lexicon of Scientific Terms."

### MEDICAL DIARY OF THE WEEK.

WEDNESDAY, FEB. 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

OBSTETRICAL SOCIETY OF LONDON.—7 P.M. Council Meeting.—8 P.M. Dr. Woodman, "On a Case of Cholera during Pregnancy."—Dr. Wynn Williams, "On Diphtheria;" and other papers.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M.

THURSDAY, FEB. 7.

ROYAL INSTITUTION.—3 P.M. Professor Tyndal, "On Vibratory Motion, with Special Reference to Sound."

HARVEIAN SOCIETY OF LONDON.—8 P.M. Mr. Teevan, "On New Aids in the Diagnosis and Treatment of Urethral Disease."

FRIDAY, FEB. 8.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL INSTITUTION.—8 P.M. Rev. W. Farrar, "On Public School Education."

SATURDAY, FEB. 9.

ST. THOMAS'S HOSPITAL.—Operations, 9½ A.M.

ROYAL INSTITUTION.—3 P.M. Mr. G. A. Macfarren, "On Harmony."

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

SMART.—On the 24th December, the wife of Bath Charles Smart, M.D., M.R.C.S., of Manchester, of a son.

CONNOLLY.—On the 16th ult., at Chatham, the wife of Dr. Connolly, of the Royal Marines, of a son.

FRY.—On the 20th ult., at Thaxted, Essex, the wife of J. W. Fry, M.R.C.S.E., of a daughter.

LONG.—On the 21st ult., at Wells-next-the-Sea, Norfolk, the wife of Frederick Long, L.R.C.P.L., of a daughter.

LINDSAY.—On the 21st ult., at Leshnaghagow, the wife of Dr. J. Lindsay, of a daughter.

ARMSTRONG.—On the 22nd ult., at Belfast, the wife of William Armstrong, L.R.C.S.I., Surgeon 16th Regiment, of a son.

MACKENZIE.—On the 22nd ult., at Weymouth-street, the wife of Dr. Morell Mackenzie, of a son.

TRAQUAIR.—On the 23rd ult., at Eccleston-square, the wife of T. G. Traquair, M.D., of a daughter.

SLEEMAN.—On the 28th ult., at Southwark-bridge-road, the wife of Dr. Sleeman, of a son, still-born.

### MARRIAGES.

TEALE-CRUTTWELL.—On the 23rd ult., at Widcombe Old Church, Bath, John W. Teale, F.R.C.S.E., of Scarborough, to Grace Mary, daughter of the late Robert Cruttwell, Esq.

HARPER-ROBINSON.—On the 23rd ult., at Braunton, Devon, Joseph Harper, L.R.C.P.L., of Barnstaple, to Augusta Mary, daughter of Capt. Robinson, of Braunton.

### DEATHS.

COWARD.—On the 19th ult., James Eyles Coward, Surgeon, of St. Peter-street, Tiverton.

EARDLEY.—On the 25th ult., John Eardley, L.R.C.P., M.R.C.S., L.S.A., of Charles-street, Westbourne-terrace.

HASLOP.—On the 26th ult., G. H. Haslop, L.R.C.P.Ed., of Buckingham, aged 60.

BLENKARNE.—On the 27th ult., Henry Blenkarne, M.R.C.S.E., of Upper Thames-street, aged 65.

FISHER.—On the 27th ult., John Wm. Fisher, Surgeon, of Huddersfield, aged 29.

CLINICAL LECTURES  
 DELIVERED IN  
 STEEVENS' HOSPITAL,  
 TOGETHER WITH  
 OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,  
 PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,  
 PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
 SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REMARKS ON CHLOROSIS AND HÆMORRHAGE.\*

(Continued from page 171.)

Amongst the nervous disturbances to which the chlorotic state is liable, I am disposed to class a very remarkable symptom, one by no means uniformly present, but yet so frequent as to demand a distinct consideration. That to which I refer is the variety of abnormal sounds which accompany the action of the heart and arteries. These sounds vary: sometimes the systolic sound is a sudden, loud, sharp sound; at other times it is rough and harsh; sometimes it is best represented by the quick transit of a whip through the air; more frequently it is the bellows-sound or murmur which reaches the ear. This murmur is not confined to the heart; it extends along the arteries, and the transmission of the blood through the veins is not always effected silently, a peculiar and remarkable sound being heard in some of the larger venous trunks. These abnormal sounds are not the result of organic disease, but arise solely from disturbance of function. This is an interesting and important phenomenon; important, because it establishes the fact, that sounds so frequently characteristic of valvular disease, may and do originate in mere functional disturbance.

As a more distinct and comprehensive account of these sounds, and the circumstances under which they arise, is nowhere to be found than in Dr. Latham's valuable lectures, I shall quote at full length his clear and emphatic description of the phenomenon, though I do not entirely agree with him in the explanation which he has given of it. After having dwelt upon endocardial murmurs as the result of mechanical impediments to the circulation, he says:—

"Certain endocardial murmurs yet remain to be noticed, which are quite distinct, pathologically, from all these. Synchronous with the systole of the ventricles, audible in the præcordial region, and extensively diffused through the arteries, resembling the bellows-sound, and so having the commonest quality of endocardial murmurs, not distinguishable by the ear from those which proceed from mechanical impediment to the passage of the blood, yet themselves springing from a different cause, they form a class by themselves, and a most important class it is. I allude to the cases in which there is an unnatural sound, both endocardial and arterial, and yet no change of structure in the heart and arteries, but a change in the relative proportions of the constituent elements of the blood. The one general fact with which the sound is constantly associated is an impoverishment of the blood, or the state in which its red globules are deficient, and its serum is in excess. Now this impoverishment of the blood would seem to stand to the endocardial murmur in the relation of a cause, from observation of their constant coincidence merely; and much more so from the observation that upon the removal of the first the second always ceases. In proportion as, under proper treatment, the blood becomes richer, and is made to abound more in red globules, the murmur waxes fainter and fainter in the heart and arteries, until it is finally altogether inaudible in both. But if this endo-

cardial and arterial murmur be really owing to an impoverished state of the blood, one would expect to find that the simple abstraction of the blood to a large amount would produce it at any time in a healthy person. And so it will. We are not, indeed, accustomed thus to bleed healthy persons purely for the sake of experiment: but healthy persons sometimes become the subject of such treatment in the case of accident and injuries, and in the first access of acute inflammation; and then we take advantage of the occasion for learning the effect of the experiment beyond the purpose for which it was instituted. And so we find that if in a healthy man we carry bleeding far enough to blanch the surface of the body, we create an audible systolic murmur in the præcordial region, and diffuse it through the arteries.

"Now this murmur is prominently characteristic of certain forms of disease; and, knowing how we can produce it at will, we should expect to find nature producing it exactly or nearly in the same way. Profuse or protracted menorrhagia, by the time it has blanched the skin, has this murmur for its sure accompaniment. Here is direct loss of blood. Chlorotic anæmia has the same. Here is no direct loss of blood, but, what is tantamount to it, a defect or failure of the assimilatory functions, whence the mass of blood is not replenished in due proportion to its expenditure upon the uses of the economy. Generally accompanying the endocardial and arterial murmur, when it is owing to anæmia or an impoverished blood, there is another sound quite different in kind, and formed neither in the heart nor in the arteries, but traceable to the same pathological condition. In following the murmur from the heart along the aorta and subclavian artery, and then above the clavicle, when you reach the carotid you find a new sound superadded to it. You perceive the bellows-murmur coming and going with distinct whiffs, and keeping time with the systole of the heart in the neck as in the chest; but in the neck you perceive, moreover, a *continuous hum*, like that which reaches the ear from the hollow of a marine shell. This is a thing so evident that it was noticed and described, and variously speculated upon, by those who first practised auscultation. But their speculations were wide of the mark. Whence or how it arose no one could tell, until the sagacity of Dr. Ogier Ward traced it to the veins, and showed it to proceed from the movement of the blood within them. The vein which offers itself most readily to the application of the stethoscope, and admits all the easy experiments which serve to certify the fact, is the internal jugular. Place the instrument on the neck, by the side of the trachea, and pretty close to it, and at the same time rest your finger upon the space between the angle of the jaw and the mastoid process; and when your ear has caught a continuous humming sound, and listened for a while and made sure of it, then press your finger firmly down upon the vein, and the sound, if it be the true venous murmur, will immediately cease; then raise your finger, and, if it be the true venous murmur, it will immediately return. A little management and address are needed to find this venous murmur, and then keep it within hearing when you have found it. I have seen it found by accident, heard for a minute, and then lost and never heard again. The instrument has been laid carelessly upon the neck and the murmur has been audible immediately; and then, in expectation of making it heard to more advantage, the neck has been put upon the stretch, the chin raised and the head thrown back, or turned far round to the opposite side, whereupon the murmur has ceased; then the neck has been relaxed, the head brought forward, and the chin inclined towards the sternum, but the murmur has not returned. The truth is, a very free current of blood is essential to the production of the venous murmur. A slight degree of pressure upon the vein will alter its character, and pressure very far short of that which would arrest the current of blood will abolish it altogether. And thus the neck being put upon the stretch, the muscles which lie parallel with the vein and across it are made to exercise pressure enough upon it to interfere with the free current of blood, and to stop the sound; or, the neck being relaxed, the veins and the integuments

get folded together, and so pressure is produced in another way, and this equally stops the sound. Try different degrees of pressure upon the internal jugular vein with the stethoscope when this venous murmur is distinctly audible, and you will find how lightly you must hold the instrument to keep it constantly within hearing, how inconsiderable an amount of pressure will obliterate it, and how each degree short of that which obliterates it will give it sundry varieties, and make it musical. Now these murmurs, whether pertaining to the heart and arteries or to the veins, which have their origin in the quality of the blood that circulates within them, furnish an eminent example of the highest degree of comprehensiveness, both for knowledge and for use, which can belong to the idea of a symptom.

"Where these murmurs are, there a countless variety of other symptoms is found in company with them, pointing to all organs of the body, and giving notice that the functions of all are going wrong; the surface pale and cold, palpitation and dyspnoea, appetite perverse, digestion imperfect, nutrition insufficient, secretions scanty and unhealthy, pain everywhere, and a shattered nervous system and an enfeebled brain. Such a portentous crowd of symptoms strikes the observation at once. But what they all mean we cannot tell, until we take one single symptom for their sole and sufficient interpreter. The murmur which is at the same time endocardial and arterial and venous is comprehensive of them all, and includes the knowledge of them all, inasmuch as it points directly to their one common source, even the impoverished blood. And further, this same murmur not only contains the knowledge of all the rest, but it is the single representative of them all as an indication of treatment. Standing as it does for the sign of impoverished blood, we treat what it denotes and nothing else. But in so doing we treat inclusively every error of function throughout the body which proceeds from it."

Such is Dr. Latham's lucid description of the nature and cause of these abnormal sounds. Are we, however, borne out by observation in ascribing them exclusively to the impoverished state of the blood? I do not think so. If this be the sole and true explanation, why does it happen that there are so many cases of chlorosis, in which the specific gravity of the blood is so low as 1.035—cases which we have examined with the utmost attention, both in the quiescent and excited states—in which this symptom is totally absent? Why is it that this symptom is not more uniformly present? Why do we find it to-day, and lose it to-morrow? Why do mental emotions and sudden exertions produce it? Why is it occasionally present in hysterical patients not labouring under chlorosis? and why is it that this symptom does not manifest itself in cases of profuse hæmorrhage which are slow and gradual, whilst it does, though not uniformly, in cases of rapid and profuse bleeding? Would it not appear from these considerations that these abnormal sounds are, in a considerable degree, dependent upon disturbance of the nervous function of the heart and arteries in excitable and hysterical constitutions? Doubtless the attenuation of the blood, both in chlorosis and profuse hæmorrhage, strongly predisposes to the production of these sounds; but their immediate exciting cause is referable to nervous disturbances; so that, to give rise to this symptom, the contractions of the heart and arteries must, from causes connected with the nervous system, be imperfect and irregular. Hence the blood is propelled in broken streams, after the manner so faithfully described by Dr. Corrigan; and although an attenuated state of the blood renders this more likely to happen, yet that condition alone will not explain the phenomenon. In reference to the subsidence of morbid sound keeping pace with the improvement in the quality of the blood, it should be borne in mind, that the treatment which most effectually enriches the blood does also as effectually restore tone and healthy action to the nerves.

(To be continued.)

## Original Communications.

### A CASE IN WHICH TYPHUS AND PYTHOGENIC FEVER COEXISTED, COMPLICATED WITH PLEURO-PNEUMONIA.

By MONTGOMERY ALBERT WARD, M.B., M.Ch.,

AND EX-MEDICAL SCHOLAR, TRINITY COLLEGE, DUBLIN; LICENTIATE OF THE ROYAL COLLEGE OF SURGEONS, IRELAND; DEMONSTRATOR OF ANATOMY AND PHYSIOLOGY, LEDWICH SCHOOL OF MEDICINE AND SURGERY, PETER-STREET.

THE question as to the identity or non-identity of the virus in typhus and pythogenic fevers has, at different times since 1840, arrested the attention of all thinking and practical physicians, for previous to this period they were considered as one and the same fever, or different stages of the same fever. Many able arguments have been advanced by the supporters of each side of the question, and even at the present time it remains to a certain extent a *questio recitata*.

Dr. Kennedy of this city has been for some time the most ardent supporter of the identity of the two fever poisons, and has brought forward many arguments to prove his views, which have been admirably answered by Dr. Hudson, in the appendix to his lectures on the study of fever, lately published.

The importance of the subject has induced me to lay before your readers the particulars of the following case, which occurred in my private practice last year, and which, I think, bears not a little on the point at issue.

May 12th, 1866, I was summoned at twelve o'clock P.M. to visit Mr. —, whom I was informed was very ill. I immediately went, and subjoined is the history of the case:—

I was informed by his family that Mr. — (who was previously a fine strong, healthy young man, aged twenty-five) had been in the habit of drinking for a year or so; that for the last six weeks his appetite had been gradually failing, and his family remarked him losing flesh, and much depressed in spirits. This day week—viz., May 5th—he was returning home intoxicated late at night, when he fell into a ditch of dirty water, near which a foul sewer emptied itself. Here he fell asleep, and lay all night with his feet and legs partially submerged, and his body on the side of the bank. In this condition he was found by some workmen going to their work in the morning, who aroused him up and brought him home, when he was put to bed. He remained in bed during Sunday, the 6th, Monday, the 7th, and on Tuesday, the 8th, he dressed and got up, but did not appear to be at all well to his friends, for he complained of being very cold, and sat over the fire all day. From this day until I saw him, a period of four days, he kept his bed, having got, as he thought, a bilious attack, for which he took some purgative medicines, which induced a slight diarrhœa. This morning he was attacked with a severe diarrhœa and a pain over the abdomen; he also complained of a slight pain beneath the left nipple. For the diarrhœa his family gave him some brandy and laudanum. Towards evening the diarrhœa increased and intense vomiting set in, when I was sent for. When I came I found him in the bed, propped up by pillows in a semi-sitting posture. During the last few hours he had passed some very fetid liquid stools, with some blood in them. The abdomen was very painful and tympanitic on percussion, and there was evident gurgillement over the right iliac region. On placing the stethoscope under the left nipple, where he complained of a severe lancinating pain, I heard a well-marked friction sound. His skin was hot and burning; pulse 120; tongue covered with a white creamy fur, and red at the edges; countenance dull and anxious; respirations hurried and increased.

As the vomiting, pain in the abdomen, and diarrhoea were the most urgent symptoms, I ordered him—

℞ Plumbi acetatis, gr. xii.  
Pulveris opii, gr. iss.  
Confect. rosæ, g, s.

M. et divide in pilulas sex capiat unam secundis horis.

℞ Sodæ bicarb. ʒi.  
Acidi hydrocyanici dil. ℥viii.  
Aquæ menthæ viridis, ʒviii.

Misce. Ft. mistura cujus capiat unciam tertiis horis.

A large linseed-meal poultice to be applied over the abdomen, and another over the left side of the thorax.

May 13th. Diarrhoea greatly moderated; vomiting still continuing, ordered ice to be sucked throughout the day, and the mixture of yesterday to be continued.

14th. The bowels were only moved once last night; vomiting entirely ceased; no pain in the abdomen; he complains, however, of the pain in the left side very much. His breathing was greatly oppressed, and there was a short cough. On examination I found that there was effusion into the left pleural sac, and for the first time to-day discovered a few rose-coloured spots over the abdomen. Ordered beef-tea and two glasses of port wine in divided portions; also a mustard poultice to be applied over the left side of the thorax. Seeing that this was a serious case, I asked for a consultation, which was granted.

15th. I saw him in consultation this day with my friend Dr. Forrest, who made a most minute and searching examination. Since last night the effusion into the left pleural sac had greatly increased, and the rose-coloured spots on the abdomen had visibly extended. Dr. Forrest and I pronounced it to be a case of typhoid fever, complicated with pleuro-pneumonia. Ordered:

℞ Calomel, gr. iv.  
Pulveris opii, gr. iii.  
Sacch. lactis, ʒi.

M. et divide in chartulas xii., capiat unam tertiis horis.

Emplastrum cantharidis 10 inches by 6, over the left side of the thorax. Beef-tea and four ounces of wine.

16th. The typhoid spots were well-developed to-day, breathing more tranquil, effusion disappearing; continues very weak. Former treatment continued, with the addition of a large blister to be applied to the posterior part of the left side of the thorax. Wine increased to eight ounces.

17th. Effusion has nearly disappeared; pain in the side continuing; cough very troublesome, expectorating a viscid sputa tinged with blood; very weak. Ordered:

℞ Ammoniac carbonatis, gr. xxiv.  
Tinct. scillæ, ʒii.  
Syrupi aurantii, ʒss.  
Infusi senegæ, ʒviii.

M. Ft. mistura capiat unciam quartis horis.

Beef-tea and wine to be continued.

18th. Slightly delirious last night; inclined to sleep very much, and very hard to be aroused; complains of no pain in the side; cough much better; tongue very dry, brown, and covered with sordes. Some maculæ appear scattered over the body, interspersed with the typhoid rose-coloured spots.

19th. Profusely maculated; wandering all night, but when aroused quite sensible. His family wished to have the opinion of Dr. Ledwich, to which I gladly consented.

20th. I saw him to-day in consultation with my friend Dr. Ledwich, who at first pronounced it to be a well-marked case of typhus fever, until I pointed out to him some of the typhoid spots which still remained interspersed through the typhus rash. It would be tedious to your readers if I detailed the daily symptoms and treatment of this case. Suffice it to say that, with the able assistance of my friend Dr. Ledwich, who continued in attendance along with me, the poor fellow appeared to be getting on very well, and we thought that he would have pulled through, when, on the morning of the 23th, a critical perspiration set in, and he succumbed the same evening.

The outlines of the above case are copied from some notes which I took for my own private instruction, as I did not

at the time intend to publish it, consequently I only hurriedly jotted down the leading features. The following are, I think, the points of interest in this case:—

First. The coexistence of the pythogenic and typhus virus.

Second. The rarity of the complication of pleuro-pneumonia.

Drs. Murchison, Hudson, Anderson, Todd, and others, have in a few cases observed the coexistence of these morbid poisons, and have in my mind clearly proved their non-identity. That they did coexist in the above case I think I have clearly proved. Now, I will endeavour to show how they were severally contracted.

In the history of this case I should have mentioned that this young man was employed in an extensive wine merchant's office in this city, and that he was engaged during the greater part of the day in the wine-vaults, which were underground, and very badly ventilated. Here he was exposed to the temptation of constantly tipping, to which he yielded, and which subsequently undermined his constitution, thereby rendering him more susceptible of imbibing a virulent poison. I believe that from constantly breathing the foul and vitiated air in these vaults he contracted the typhus poison, and that he contracted the pythogenic poison on the night of May 5th, when he lay all night in a ditch, near which a foul sewer opened. This is, I think, what probably took place, at least it is the only way in which I am able to explain it, after a close investigation into the history of the case.

With regard to the complication of pleuro-pneumonia, which is another interesting feature in this case. I am well aware that pneumonia *per se* very often occurs, but the existence of pleuritis is very rare indeed. Dr. Hudson has only seen three examples of this complication in the numerous cases which have come under his notice.\*

## Hospital Reports.

### MEATH HOSPITAL.

#### REMOVAL OF AN ENLARGEMENT OF THE SUPERIOR MAXILLARY BONE.

By Mr. COLLIS, Surgeon to the Hospital.

ON Thursday last, the 7th instant, the theatre of the Meath Hospital was filled with a crowd of students and surgeons to witness the performance of an operation which excited more than usual interest, in consequence of the subject of the operation being a gentleman well-known in the city of Dublin. This gentleman had from childhood suffered from an enlargement of the superior maxillary bone on the left side. During the last two years it had grown with considerable rapidity, and it was finally determined to remove it before it began to press on any vital part.

Mr. Maurice Collis, who performed the operation, began by detaching a layer of bone from the base of the tumour, so as to leave the hard palate and roof of the mouth perfect. An incision was then made from the inner angle of the eye, along the side of the nose, and through the lip, a little external to the mesial line. The soft coverings of the tumour, including the periosteum, were drawn to either side, and its attachments to the malar bone were divided by a strong forceps. The tumour was, by degrees, isolated from the floor of the orbit; this stage of the operation was tedious, owing to the ivory hardness of the bone at this part. The bulk of the tumour was thus detached and removed, leaving a small portion behind which was of softer texture, and which was removed by the gouge. The cavity of the nostril was not opened, as the periosteum of the tumour peeled off readily on that side. Considering

\* Vide Study of Fever, by Dr. Hudson, Lecture XV., page 253.

the severity of the operation, the hemorrhage was trifling; but three arteries in the soft parts required ligature, while some jets from the bone were restrained by the galvano-caustic. The flaps were brought together with numerous points of horse-hair suture—a small space being left open about the site of the incisor teeth to give exit to some light dressing, ligatures and discharges. The patient was chloroformed throughout, and seemed to suffer little from the shock.

### GUY'S HOSPITAL.

#### EXTIRPATION OF BOTH OVARIES.

(Under the care of Dr. OLDHAM and Mr. BRYANT.)

A MARRIED woman, 35 years of age, mother of two children, was admitted to Guy's Hospital on the 25th of last March, with polycystic disease of both ovaries. She had observed a progressive enlargement of the abdomen for nearly a year. The diagnosis having been made out, and an operation having been advised and agreed to, Mr. Thomas Bryant performed ovariectomy on the 14th of April. Upon incision, a little ascitic fluid escaped, and the cyst, when exposed, was found firmly attached by a number of adhesions. They were torn through, and two of them tied. The pedicle was ligatured and dropped in, the ends being cut off short. Some cystic disease being discovered in the opposite ovary, this was also removed, and the pedicle also dropped in. The wound was immediately closed, the patient placed in bed, and an opiate given in the form of suppository.

Some vomiting occurred after the operation, and another suppository was given in the evening. Nevertheless, the patient had little sleep during the night, and vomited several times. In the morning the pulse was weak, 120, and she suffered from pain in the abdomen. These symptoms continued in spite of treatment, and she died on the 16th.

This case may remind some Guy's students of a similar one admitted under the same gentlemen three years before, and treated in the same manner, but which was also, unfortunately, followed by a fatal result. The patient was also married, about the same age (being 32), and had had one child. She was admitted in April, 1863. Tapping, however, had in this instance been resorted to. Ovariectomy was performed by Mr. Bryant on the 15th April. There were extensive adhesions to the viscera as well as to the parietes, and when the cyst was removed the other ovary was found to be diseased, and consequently was extirpated. Sickness and peritonitis followed, and the patient died within twenty-four hours after the operation.

We have thus briefly recorded these two interesting and instructive cases, occurring in one of our leading schools, with a sincere desire of placing before our readers the modern practice of the metropolis. It would, perhaps, conduce to more valuable statistics were all the cases in which such important operations are performed briefly recorded. It would seem now to be a common practice to cut off the pedicle close to the ligature, drop it into the abdomen, and at once close the wound—a method which commends itself strongly for its simplicity, and, one may add, its success. In three cases of ovariectomy at Guy's last year, of which we have notes, and which we suppose were his three most recent cases, Mr. Bryant adopted this procedure, and all three happily terminated in recovery.

### THE LONDON HOSPITAL.

#### TRANSVERSE COMPOUND FRACTURE THROUGH BOTH UPPER MAXILLÆ.

(Under the care of Mr. HUTCHINSON.)

A YOUNG man was admitted lately, under Mr. Hutchinson's care, into the London Hospital, with a very rare form of fracture of the upper jaw. His head had been jammed between a "lift" and a cross-bar, and probably one part

twisted on the other. On admission he had copious bleeding from his nose and mouth, and his eyelids were ecchymosed, leading to the suspicion of fracture of the anterior part of the base of his skull; but on passing the forefinger into the mouth, Mr. Hutchinson found a transverse fracture, which would admit the end of his finger, passing right across both upper maxillæ from side to side, and communicating with the nose and both antral cavities. The alveolus, containing all the teeth, was completely separated and depressed about half an inch, but was loose and could be easily lifted into place.

Various plans suggested themselves as regards retaining the bone in place, but Mr. Hutchinson contented himself with simply bandaging the lower jaw firmly against the upper one, as this procured very fair apposition. A wedge of gutta serena was placed between the molar teeth on each side.

In a few days an abscess formed in the left cheek and was opened. He is doing very well, and there seems every probability that no exfoliation will take place, and that all the teeth will be saved.

It will be seen that the fragment detached by the line of fracture comprised the entire alveolus, with all the teeth on both sides and the whole of the hard palate. Probably it included also the lower parts of the pterygoid processes, but this point was not ascertained positively. Above the line of fracture the thin plates of bone were much comminuted, and probably the left orbit was involved.

## Foreign Medical Literature.

### ON NERVOUS ASTHMA.

By BAMBERGER.

Translated from the *Norsk Magazin for Lægevidenskaben*, xx. Band, 1 Hefte, 1866, p. 60.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

[The case which gave rise to the following remarks appeared originally in the *Würzburger med. Zeitschrift*, 17 Band, i. and ii. Hefte, 1865, whence they have been translated into the *Norwegian Magazine of Medical Science* by F. Kiær. Not having access to the above-named German journal, I shall translate the author's remarks from the Norwegian version; the details of the case itself I do not think it necessary to reproduce.—W. D. M.]

NERVOUS asthma, the existence of which it is in the present day no longer necessary to prove, may be best divided into a central and eccentric or reflex asthma. The first is a very rare form of disease, whether it be based upon material changes, or these cannot be demonstrated; reflex asthma, on the contrary, cannot be considered as so very rare. The abnormal irritation, the conduction of which takes place chiefly, if not exclusively, through the vagus, proceeds in most cases from the respiratory organs, and asthmatic attacks of undoubtedly nervous nature are by no means uncommon in the most different pulmonary affections, especially in emphysema, but also in violent catarrh, pleuritis, tuberculosis, &c. The so-called hay asthma is likewise a reflex asthma, depending on very extensive bronchitis. In general it is not difficult to distinguish such a nervous attack from the mechanical dyspnoea dependent on the presence of the pulmonary affection. Nervous asthma in an emphysematous patient differs very essentially from the pseudo-asthmatic dyspnoea, which the same patient experiences at another time in acute catarrh, or where there is a large accumulation of mucus. That the irritation may also proceed from other organs, can scarcely be matter of doubt, although on this point we know little positively. That asthmatic attacks may be caused by dis-

eases in the heart and aorta, may be regarded as tolerably certain, although on account of the pulmonary affection almost invariably coexistent therewith, it is difficult to prove that the abnormal irritation proceeds exclusively from those organs. Undoubtedly there exists an hysterical asthma, which ought more correctly to be looked upon as of central origin. On the other hand, the theory which considers asthma as a symptom of gastric, hepatic, splenic, and intestinal affections; that of hemorrhoidal asthma, and of asthma in tapeworm, in renal diseases (the so-called asthma urinosum is nothing else than pulmonary oedema), and in those of the sexual organs would not now, as it did of old, find many adherents, yet we ought to beware of too unconditionally, and without further examination, entirely rejecting the older theories.

The case above recorded is indeed with great probability to be considered as one of reflex asthma, proceeding from the lung. At least it appears from the history of the case that a violent catarrh had preceded the attacks, and this view was confirmed by the post-mortem examination. As to the finely vesicular emphysema, we may without any hesitation regard it as a secondary phenomenon, produced by the extremely violent disturbances of respiration, but the state of the case would not in any essential point be altered, were we to look upon the emphysema as pre-existing, for which, however, there is not the slightest reason. The other changes in the body present nothing of special interest. The dilatation of the right side of the heart, which, moreover, took place to a moderate degree, is a result of the emphysema. The moderate thickening of the left ventricle can be brought into causal relation only to the atheromatous process in the arteries, just as the systolic bellows' murmur, observed along the aorta during life, can be explained only by the thickening of the inner coat of that vessel. The firm and hyperæmic state of the spleen and kidneys and moderate degree of hydrocephalus are to be considered only as results of the disturbance of the circulation.

But what in this case especially interests us is less the causal relation, which will long continue as obscure as are most of the neuroses, than the mode in which the asthmatic paroxysm manifested itself, and the physical state upon which this depended.

What, properly speaking, is nervous asthma, and how is it developed? To this question we obtain, with rare unanimity, the answer—Nervous asthma depends upon spasm in the bronchi, and mainly in the finer, contractile fibre-cells. Bergson in particular, in his well-known monograph, has taken the greatest trouble to prove this upon negative and positive grounds, but unfortunately without the slightest success. There is just now no other reason given for this view than the mere presence of those muscular elements, which, indeed, involve the possibility, but by no means consequently the actual existence of such a spasm.

Up to the present, however, only Wintrich has appeared in opposition to this generally received hypothesis, and it may be said that Wintrich's statements contain more sound reason than all hitherto written upon nervous asthma. Wintrich does not indeed deny the possibility of a spasm in the bronchial muscles, but that such can be the cause of nervous asthma, and this for two reasons. In the first place, he observed several cases of the disease, in which the diaphragm during the attack lay very deep and immovable, where manifestly there was only tonic spasm of the diaphragm, while this phenomenon cannot possibly occur in bronchial spasm. In the second place, both the inspiratory and expiratory forces are considerably greater than the sum of the forces of the bronchial muscles. I am myself indeed quite of the opinion, that hitherto there is no warrant for the assumption of bronchial spasm as the cause of asthma, and that the causes of the latter must, in the majority of cases, be sought elsewhere; but it, nevertheless, appears to me that it is going too far completely to deny the possibility of such a condition. Against these arguments it may, in fact, be objected, that, in the first place, it is not proved that the diaphragm in all cases of

nervous asthma is found to be situated low down and immovable; and in the second place, the preponderance of both the inspiratory and expiratory powers over the powers of the muscular pulmonary elements may indeed be admitted, but this does not hinder us from assuming a conflict between the two, and it is precisely upon this that the asthmatic attack might depend. We might, therefore, simply assert, that in such a conflict the final victory must always remain with the "legitimate" respiratory powers as the stronger, or, in other words, that no one could be suffocated in an attack of purely nervous asthma.

If we now return to our case, there can be no doubt that in it there could have been no such thing as spasm in the bronchi. Even the deep position of the diaphragm in itself renders such a theory impossible. I will, moreover, hereafter revert to the symptoms which must attend spasm in the bronchi, and it will be seen that most of them are directly opposed to those observed in the case in question.

On the other hand, all the phenomena may, with almost mathematical accuracy, be accounted for by the existence of a tonic spasm in the diaphragm and secondary antagonistic spasms in the expiratory muscles depending thereon. The low position and immobility of the diaphragm, in spite of enormous efforts of its antagonists, in connexion with the unyielding nature of the lower half of the thorax, is, in this case, the decisive and convincing element. The absence of respiratory murmur in the lower part of the chest is easily explained by the absolute immobility of the parts of the lungs lying above the diaphragm. Inspiration could take place in the upper parts only with the aid of the superior, and especially of the cervical respiratory, muscles. The inspiratory increase of the capacity of the chest on a level with the xiphoid cartilage, in spite of the complete immobility of the diaphragm, is essentially to be considered only as a diminution of the contraction of the thorax effected during the expiratory spasm by the abdominal muscles. But one phenomenon is more difficult of explanation—namely, the distinctly tympanitic sound in the lower part of the thorax during the expiratory spasm. When the attack occurred, and the diaphragm suddenly assumed its low position, the inferior portions of the lung must have been suddenly inflated. During the expiratory spasm the abdominal muscles must strongly compress the thorax, and thus the pulmonary cells and their membranes must come to be under a very strong pressure. But how is the tympanitic sound to be thus explained? According to Skoda's theory this circumstance—namely, great tension of the cell-membranes, would produce exactly the opposite effect.

After having quoted a couple of theories, which, however, do not seem to the author sufficient to explain the symptoms described, he continues:

"We may therefore say that the picture we might, *a priori*, form of a tonic spasm of the diaphragm and that observed in my patient, completely correspond to one another. Moreover, from Duchenne's experiments on animals, we are acquainted with the symptoms of tonic diaphragmatic spasm produced by electrical stimulation of the phrenic nerves. They agree in all essential points with the phenomena observed in my patient; only the results of percussion are not mentioned by Duchenne; however, these fall away of themselves, as they are dependent merely on the low position of the diaphragm." In the human subject Duchenne has not seen tonic spasm of the diaphragm, but he quotes a case observed by Valette, in which death was caused by spasm in that muscle supervening during an attack of acute rheumatism. The symptoms, with the exception of the state of the abdominal muscles, agreed completely with those experimentally produced by Duchenne: "the abdominal muscles exhausted themselves in vain efforts to contract the base of the thorax". In this instance nothing was seen of these fruitless efforts on the part of the abdominal muscles, which were so very striking in our case. Duchenne explains this difference correctly by showing that with this painful rheumatic contraction of the diaphragm a corresponding antagonistic action of the abdominal muscles

could not take place, because the pains would then be increased; the patient would, on the contrary, be compelled to exert himself to keep these muscles as quiet as possible.

In my patient the tonic spasm of the diaphragm, which attained its greatest height during the attack, seemed not to have entirely ceased in the intervals, at least not in the latter period of the patient's life. The striking slowness of respiration and the invariably increased action during expiration appear to me to prove this. Certainly the diaphragm was movable in the intervals, but the excursion did not, on the deepest inspiration, amount to more than an inch, which is much less than the normal range. Certainly the position of the diaphragm in the intervals also corresponded to the normal, but an increase of the usual tension, a kind of sub-tanic condition, is also possible without change of position.

There is consequently not the least doubt that there are asthmatic attacks whose cause lies in a tonic spasm of the diaphragm. In addition to the case now communicated, I remember two others where the paroxysms, if not quite as violent, were so like those here described that I have no doubt that they had the same origin. We have, moreover, the case observed by Wintrich, in which I find only the striking circumstance that the spasm of the abdominal muscles is not mentioned.

I have no doubt that spasm of the diaphragm is the most frequent and most important, but by no means the only cause of nervous asthma. To this opinion I was led even by the fact that, in reflecting on the various attacks of this kind in different patients, I find a very essential dissimilarity in the elements composing the attack, and in its whole bearing. In one case the spasm had a more inspiratory, in another a more expiratory character. At one time these, at another those respiratory forces were in increased activity. On account of the complicated nature of the respiratory act we can imagine different possibilities, whose existence must certainly, for the most part, first be proved.

Thus it appears to me, that the paroxysm in many cases is due to a mere clonic spasm in all or in the majority of the muscles of inspiration; for example, in hysterical asthma (I do not mean the hysterical spasm of the glottis). At least there was in the cases of this kind which I myself observed, always an extremely vehement panting respiration, with the co-operation of all the auxiliary muscles of inspiration, with a perfectly free passage through the larynx. Expiration took place with ease, although it, of course, in correspondence to the inspiration, was deeper and stronger than usual. However, I do not mean hereby to assert that other forms of asthma may not occur in hysterical patients, or that this form is found only in such patients.

Another possibility lies in paralytic states of the diaphragm. It is well known that this state has been observed in the human subject by Duchenne (especially in progressive muscular atrophy, then in lead-cachexy, hysteria, inflammation of the abdominal organs), and it has been produced in many instances, experimentally, by dividing the phrenic nerves. In many cases distinct asthmatic symptoms occurred; in some, on the contrary, the phenomena were not very considerable. Gerhardt, too (*Der Stand des Diaphragma*, Tübingen, 1860), correctly calls attention to the fact that the diaphragm obtains motor branches, not only from the phrenic nerve, but also from the 7th, 8th, 9th, 10th, 11th, and 12th intercostal nerves. It is, indeed, even *a priori*, probable, that such forms will be distinguished by their longer duration. The symptoms which depend on a paralysis of the diaphragm, especially the physical signs, are very accurately described by Duchenne, and particularly by Gerhardt. The diagnosis would, in the concrete case, not be more difficult than the diagnosis of diaphragmatic spasm.

As another possible case, of the existence of which there certainly is at present no proof, we may mention a spasm in the expiratory muscles alone, and principally in the abdominal muscles. In this case the muscles of inspiration must come into increased activity.

Lastly, there remains spasm in the bronchial muscles, which has the least amount of probability in its favour,

but, nevertheless, is not inconceivable. What physical signs should we expect under such a condition?

As such a spasm would obstruct both respiratory acts, but expiration has a greater amount of forces at its command, both inspiration and expiration must certainly be laboured, prolonged and combined with great effort of the respiratory muscles, but this would be in a still higher degree the case with inspiration. The diaphragm would probably stand high, the thorax would be diminished in all directions, and the intercostal spaces would be more strongly drawn in, a very considerable increase of the expiratory, and especially of the inspiratory murmur, would necessarily be perceptible. Accordingly as the air, after having overcome the obstruction, could stream into the cells, or as this would be impossible, so must the character of the inspiratory murmur be either vesicular or undefined. In high degrees we might imagine the possibility of a moderate diminution of the resonance of the sound on percussion.

In glancing back briefly on what has been advanced, the conclusion must appear to be fully justified, that nervous asthma depends on different kinds of lesion of motor innervation. The form observed by Wintrich and by me, which depends on tonic spasm in the diaphragm, has been fully established. Scarcely doubtful can that form be considered which depends on paralysis in this muscle; all other possible cases must first be proved hereafter by accurate observations.

In a therapeutical point of view, spasm of the diaphragm has probably most to expect from the uninterrupted current; paralysis, on the contrary, has most to look for from inductive electricity. (The employment of electricity was, in the above case, prevented by the sudden death of the patient.)

## SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[THE Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### OZONE.

Dr. Charles Daubeny has communicated a long paper on ozone to the Chemical Society. He says ozone must exist in the air; and this being the case, we are led to assume its presence whenever those reagents which detect it in a mixture are affected in the same manner by the passing of air over them.

Paper soaked in a solution of iodide of potassium with starch is the most delicate of the tests; also, a very good test is the protosulphate of manganese. It has been objected that nitrous acid and chlorine would produce similar reactions. "I think, however," says the author, "that it may be proved that neither of these gases exist in the air, which, according to my observations, affect Schonbein's paper" (iodide of potassium and starch). Nitrous acid is generated by electrical phenomena, and chlorine will probably be present near the sea.

Proper care must, however, be taken to exclude direct sunlight, which alone is sufficient to separate iodine from its combinations, so as to produce the blue colour with starch.

From Dr. Daubeny's observations it would appear that in Devonshire, when the wind is blowing from the south-west and west, there is most ozone. After these points the south is richest; east, north-east, and north-west are nearly alike; south-east is still lower, and north is lowest of all. These results were not the same when compared with some made at Oxford at a different season of the year, and he found that the same laws did not hold good.

When water is decomposed by electricity ozone is liberated

at the oxygen pole. As, therefore, the principal agent for restoring oxygen to the air when vitiated by animal processes is vegetation, we might naturally expect that ozone should be disengaged by the leaves of plants during their exposure to sunlight. Dr. Gilbert, however, failed in procuring ozone from leaves exposed to sunlight, but the author's experiments go to prove the contrary.

Leaves, according to Dr. Daubeny, do not appear to give out ozone in the dark; nor do flowers give off ozone. "May not this seem to account for the injurious effects upon health ascribed to flowers when placed in large quantities in sleeping apartments? This has been ascribed by some to the oxygen they consume, but their influence," says the author, "must be inappreciable, and their insalubrity is due to the destruction of ozone by them."

In connection with the part ozone plays in the economy of nature, Dr. Daubeny says—"Plants, indeed, decompose carbonic acid, and thus serve to maintain unaltered the original composition of the atmosphere; but the various products of putrefaction, the emanations from animals, living as well as dead, the exhalations from swamps and marshes, would still continue to contaminate it, were it not for the presence of some agent capable of removing those bodies from the fluid in which they are floating, and of rendering them innocuous by oxidation."

#### CONIUM IN CONII FRUCTUS.

Dr. Harley, from some communications, &c., published in the *Pharmaceutical Journal*, comes to the conclusion that the *tinctura conium* B.P. is inert, and that the fruit is perhaps not so rich in conia as supposed. He (Dr. Harley) had drunk ʒij. of a carefully-prepared tincture without any apparent effect. Dr. Garrod and Professor Bentley thought that the activity of the fruit had been underrated. The latter gentleman said that the fruit contained the largest amount of conia just before it arrived at maturity, and that there are grave doubts whether the fruit did not deteriorate by keeping. Dr. Harley says, in connection with this subject: we know that the active principle of the poppy is more abundant in the circulating juices of the green fruit than in any other part. It is very probable that this is the case with conium, and that we must look for the greatest accumulation of its active principle in the green immature fruit.

#### ON THE FORMATION OF CELLS IN ANIMAL BODIES.

The following is the substance of a communication from E. Montgomery to the Royal Society:—

The so-called organic "cells," chiefly those of various cancerous tumours, were seen on the addition of water to expand to several times their original size, and at last to vanish altogether into the surrounding medium.

The "nucleus" did not always participate in this change, but at times remained unaltered, whilst the outer constituents of the "cell" were undergoing this process of expansion.

This curious phenomenon of extreme dilation is intelligible only on the supposition that the spherical bodies in question are in reality globules of a uniformly viscid material, which by imbibition swells out till at last its viscosity is overcome by the increasing liquefaction.

In embryonic tissues, and in various tumours, single "nuclei" were seen, each surrounded by a shred of granular matter. On the addition of water there would bulge from one of the margins of the granular mass a segment of a clear globule, which continued growing until it had become a full sphere, which ultimately detached itself, and was carried away by the currents. At other times no such separate globule would be emitted, but the entire granular shred would itself gradually assume the spherical shape, ultimately encompassing the "nucleus," and constituting with the same the most perfect typical "cell."

Not only single "nuclei" were found surrounded by a shred,

but also clusters of two, four, and more were seen similarly enclosed by a proportionately large granular mass. Under these circumstances it sometimes occurred that, on the addition of water, the whole granular mass of such a cluster became transformed into a large sphere containing two, four, or more nuclei. The resulting body was to all appearance identical with shapes well-known under the name of "mother-cells." In all these cases the granular shred must have partly consisted of a viscid material, which on imbibition naturally assumed the spherical shape.

The author then proceeds to his experimental verification. In all the observations cited by the author, the existence of a viscid imbibing material was proved with almost conclusive evidence—a viscid material which is capable of forming globules of a definite size, and while in the living organism actually forms such globules, shapes, the nature of which has hitherto been mistaken. After a long search the substance known under the name of myeline was found to be the desired material. When to myeline, in its dry amorphous state, water is added, slender tubes are seen to shoot forth from all the free margins. These are sometimes wonderfully like nerve tubes in appearance. They are most flexible and plastic. From this curious tendency of shooting forth in a rectilinear direction, it was inferred that a crystallizing force must be at work. To counteract this tendency, and to oblige the substance to "crystallize" (!) into globules, it was intimately mixed with white of egg. The result was most perfect. Instead of tubes, splendid clear globules, layer after layer, were formed, resembling closely those of the crystalline lens formed under similar conditions.

Here was actually found a viscid substance which, on imbibition, formed globules of a definite size. The remaining task was comparatively an easy one. By mixing the myeline with blood-serum, globules were obtained showing the most lively molecular motion. Thus, says the author, "cells" being merely the physical result of chemical changes, they can no longer afford a last retreat to those specific forces called vital. Physiology must aim at being something more than the study of the functions of a variety of ultimate organic units. And pathology will gain new hopes in considering that it is not really condemned to be the interpreter of the many abnormalities to which the mysterious life of myriads of microscopical individuals seem to be liable.

#### ON THE PURIFICATION OF SULPHATE OF SODA, ETC.

M. Jeannel, in a communication addressed to "Cosmos," proposes to take advantage of the phenomena of supersaturated solutions for the purification of some of the commercial salts.

To purify sulphate of soda the author dissolves 300 grammes of the commercial salt in 100 of water, at a temperature of 33° C. At this temperature the 100 grammes of water are able to take up 322 grammes of the salt. At the same time a filter is placed in a funnel, with about 500 grammes of hot water, at 50°; when the water has all run through, place the solution of soda upon the filter and cover with glass. The solution passes all through the filter and remains liquid for some time after it is cool. When crystallized the salt is separated from the mother liquors, and dried at 33° C.

Sulphate of magnesia, sulphate of zinc, and carbonate of soda are easily purified in this manner; it is not applicable to alum, as that salt crystallizes in the filter. Some salts may be effectually separated, according to M. Jeannel, by the difference of their saturating power. He gives as an instance nitrate of potash and alum. The first-named salt, he says, crystallizes from a saturated solution of alum as if it were in pure water.

#### ON THE EXTRACTION OF DELICATE ESSENTIAL OILS.

It is a well-known fact that the volatile oils to which such flowers as the jasmine, violet, heliotrope, &c., owe their aroma, are destroyed by distillation, and thus the substitution of *enfleurage*, or the process of extraction by fats. MM.

Millon and Camille Schwaier propose to use bisulphide of carbon for extracting aromata from such flower, as it boils at a very low temperature—viz., 110° Fahr.

Mr. Tichborne proposed this application some years since, but preferred chloroform, as the ordinary bisulphide of carbon is so impure. Mr. Tichborne proposed the use of glycerine for extracting the aroma, and then treating this with chloroform or bisulphide of carbon. M. Schwaier proposes to extract with bisulphide of carbon, to treat with almond oil, and then again to extract the aroma from the oil with spirit.

#### AMALGAMATION.

Mr. Nickles (*Journal de Pharmacie et de Chimie*, vol. iv., p. 330) gives us his observations as regards the action of sodium amalgam—i.e., mercury containing a minimum of sodium—and now used with success in mining operations. If a drop of common mercury is allowed to fall upon a leaf of gold cemented upon glass, the drop will adhere and become fluid without increasing perceptibly in extent; but a drop of sodium amalgam will extend with astonishing rapidity, eating its way, and whitening all around it.

Silver and copper leaves are not so easily permeated by the amalgam.

Amalgams of iron and platinum are obtained in the following manner:—To amalgamate iron it is only necessary to rub the metallic sheet with a zinc or brass brush, dipped in acidulated water, and add a drop of mercury. In this case the amalgamation takes place by virtue of a galvanic effect, produced by a metal which, like sodium or zinc, is more positive than iron.

Amalgams of sodium attack platinum and aluminium, but are without action on magnesium.

When metals which are not wetted by mercury have been amalgamated by an indirect method—such as by sodium amalgam—the mercury remaining on the surface does not penetrate into the depth of the metal, and consequently does not render it brittle.

#### ARTIFICIALLY CRYSTALLIZED OXALATE OF LIME.

M. Monier obtains fine crystals of oxalate of lime by reversing a vessel containing a diluted solution of oxalic acid into a dense solution of sucrate of lime.—(Liq. Calcis, Saccharatus.)

Ammonio-magnesian phosphate may be obtained in a similar manner.

#### MERCURIC OXALATE.

Mr. J. Richardson, in a communication to the editor of the *Chemical News*, says that he found the mercuric oxalate to be explosive on rubbing it up in a mortar, evolving a poisonous vapour, which irritates the throat and occasions coughing. The author says that it becomes decomposed, on heating, into metallic mercury and carbonic acid.

#### ACTION OF CHLORINE ON AMYLENE.

M. Bauer says that chlorine is absorbed by amylene without the disengagement of hydrochloric acid:—

Chlor-amylene  $C_{10}H_9Cl$ , boiling at 130° Fahr.—139° Fahr.

Chloride of amylene  $C_{10}H_{10}Cl_2$ .

Chlorinnetted chloride of amylene  $C_{10}H_9Cl_3$ , crystallizes.

Bichlorinnetted chloride of amylene  $C_{10}H_8Cl_4$ , a heavy liquid boiling at 73·4-75·2 Fahr. are formed.

#### CHLORO-SULPHIDE OF PHOSPHORUS, CHLORO-SULPHIDE OF CARBON, ETC.

M. Chearier has obtained a chloro-sulphide of phosphorus ( $P Cl_3 S$ ) by acting on chloride of sulphur by phosphorus. It is a liquid boiling at 125° C. Two modifications of sulphur are deposited from the residues on drawing off the chloro-sulphide; one crystallized in prismatic needles, which are opaque, the other in octahedra, are transparent and very brilliant.

Mr. W. Hartley (*Journal of the Chemical Society*) has isolated a chloro-sulphide of carbon,  $C^2 Cl^2 S^3$ , the name appli-

cable under these circumstances being chloro-sulphoform—a body of the composition  $C^2 H^2 S^3$  being already known and called sulphoform it being chloroform in which sulphur replaces chlorine.

*Silk Collodion*.—M. Persoz makes a collodion by dissolving silk in warm chloride of zinc, the latter being removed by Prof. Graham's method of dialysis.

*Relation between the Products of Oxidation*.—M. E. Chapin and W. Thorp continue their researches upon the above subject. Glycerine and mannite resemble each other in many particulars. They both yield iodides of secondary alcohol-radicals when treated with hydriodic acid and these iodides, olefines, when acted upon by alcoholic solution of potash, &c. Glycerine when heated with caustic potash yields acetic and formic acids. Mannite yields propionic, acetic, and formic acids. Both mannite and glycerine are converted into carbonic and formic acid by the direct action of chromic and permanganic acid; no other acids are formed in their reactions. In the case of the oxidation of permanganate of potassium on mannite, the action was as follows:—

Mannite. Formic acid. Water.

M. A. Wurtz has described a new class of compound ammonias. The isomerism exhibited between pseudo-amylc alcohol extends to the ureas and to the ammonias. The new ammonia (isoamylamine) is prepared by heating pseudo-amylurea for some days with caustic potash. Isoamylamine has a strong ammoniacal odour, precipitates metallic oxides, and dissolves oxide of copper.

*Crystallization of Glycerine*.—Mr. Crookes has noticed that glycerine is capable of crystallization. Five tons which were sent from Germany were found on their arriving in London to have solidified to a solid mass. Mr. Crookes attributes this phenomenon to the vibrations of the railway journey across Germany added to the intense cold. The glycerine seemed pure and was tested for sugar and glucose—when once fused it could not be recrystallized.

*Action of Mannite upon the Potassio-Tartrate of Copper*.—M. Bodenbender, according to the *Bulletin de la Société Chimique*, had stated that mannite reduced the copper salt. M. Wittstein brings forward experiments to prove that pure mannite is without reducing action, and that M. Bodenbender's mannite must have contained some other sugar. The action of mannite is so well known that we are surprised that the statement required contradicting.

*Double Salt of Ferrocyanide of Potassium and Nitrate of Potassium and Soda*.—This salt has been obtained in the manufactory of Mr. R. Dale, of Warrington. A short notice has been published by M. Martius. It forms fine bright yellow crystals, belonging to the hexagonal system; exposed to the air their surface becomes green. They are phosphorescent and detonate like powder when heated suddenly.

*Estimation of Tannin*.—M. Wagner uses for the estimation of tannin, sulphate of cinchonine; a little acetate of rosaniline is used with it.

Young oak bark contains	10·80	per cent. of tannin.
Ordinary oak bark	6·25	"
Pine bark	7·33	"
Beech bark	2·00	"
Sumac, 1st quality	16·50	"
" 2nd "	13·00	"
Valonia, 1st "	26·75	"
" 2nd "	19·00	"
Dividivi (husks of caesalpinia coriaria)	12·00	"
Grape seeds	6·50	"
Hop "	4·25	"

M. Schulzeff uses a saturated solution of sal-ammonic

when estimating tannin by gelatine; this cause the precipitate to fall easily.

In the first process the rosaniline is merely used to indicate the end of the reaction. Sulphate of cinchonine is easily obtained pure by crystallization, 1'554 parts of the precipitate of tannin and cinchonine salt contained '430 of cinchonine.

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, JANUARY 18, 1867.

Dr. BUTCHER, President of the College, in the Chair.

#### SCALD OF THE GLOTTIS.

DR. J. K. BARTON said—The subject of scalds of the throat and larynx has attracted more attention in this country than elsewhere—I suppose from the fact that the habits of our poor people lead much more frequently to the peculiar circumstances which give rise to the accident; and it is a curious fact, showing how slowly experience makes any change in the habits of the poor, that the custom of children drinking from the spout of a kettle continues to-day, as it was fifty years ago, to be the constant—I might almost say the sole—cause of this dangerous accident.

The French authors Barthey and Rilliet, in their admirable work "On the Diseases of Children," call this an English accident, arising from the common use in England of tea-kettles. They might have still better called it an Irish accident, indeed all they knew upon the subject they acknowledge to have received from the Irish authors, Burgess, Wallace, and Jameson; and the English, Marshall Hall. The accident seems unknown in France, save by description.

Dr. Bevan, in an able paper upon this subject in the last number of the *Dublin Quarterly Journal*, insists most truly upon the importance of our holding true and accurate views of the pathological effects produced by this accident, before we can arrive at a satisfactory rule of treatment, and contends that the cause of death is *not* mechanical obstruction in the larynx, preventing the admission of air to the lungs, but inflammatory action of the lungs themselves, produced either by the heated vapour being drawn into the lungs at the time of the accident, or by the rapid extension of inflammation over the trachea and bronchi. I think all who read the proofs Dr. Bevan has adduced of this, in the paper I have referred to, will agree with him that in the vast majority of cases which prove fatal, death has resulted from inflammation in the chest, and not from obstructed larynx. Still, in looking over the cases recorded by Marshall Hall, Bryant, and others, it will be seen that in several cases death has taken place suddenly, and before there was any evidence of pulmonary lesion, the cause appearing to be spasm of the glottis, which was found after death to be obstructed by the œdematous and swollen state of the mucous membrane covering the epiglottis, atemo-epiglottidean folds, and even the true chordæ vocales; so that I think we are compelled to acknowledge that in some instances death results directly from the injury to the larynx, while in the majority of fatal cases death results from secondary inflammation in the lungs; but we must not forget that this inflammation, whether it be of the bronchi or substance of the lungs, is caused by the injury to the larynx, and that this fatal effect of the scald does not come on for one, two, or often many days after the injury. Three different explanations have been offered of the fact that inflammation of the bronchi or lungs so frequently follows this injury. Dr. Bevan suggests that it may be that the child, in attempting to resist the swallowing of the water, forces or draws some of the heated vapour down into the lungs, where it causes inflammation of the delicate lining membrane of the bronchi; or again, he suggests that the sympathy is so great between the different parts of the respiratory organs in children, that as soon as the glottis is inflamed, the disease spreads rapidly over the entire respiratory tract. Mr. Bryant, having observed that in cases where he performed tracheotomy, milk which the child was attempting to swallow came out of the canula, suggests that the glottis having lost its healthy irritability, and allowing substances thus to pass down into the bronchi, that these may have excited the subsequent inflammation which took place. Now, while ac-

knowledging the influence which each of these causes may have in particular cases in producing the subsequent inflammation, I would suggest that there is in all these cases a powerful predisposing cause, tending to produce inflammation in the chest, which it is most important to recognize, and this is, the congestion of the lungs which invariably follows any serious obstruction to free respiration. In a few hours after the hot water has been taken into the mouth, the child begins to breathe with a loud croupy sound; the face becomes purplish; there is, in fact, every evidence of obstructed respiration, the cause of which we have abundant reason to believe is a swollen, œdematous state of the upper opening of the glottis. When such an obstruction exists, it requires no argument to prove that the lungs will be congested, and the longer this congestion lasts, and the more extreme its degree, so much greater will the danger of subsequent inflammation become. In one of Mr. Bryant's cases, where death took place, and where there was great, but not complete, obstruction in the larynx, he found the trachea and bronchi congested and filled with mucous, the lungs gorged with blood, and the cervical veins much distended.

It follows, I think, from this, that if we see a case of this kind early, our treatment ought to be directed to the swollen œdematous glottis, which, by obstructing the free passage of air to and from the lungs, is producing congestion of these organs, which advancing to inflammation, will be the cause of death. If we can remove the cause the consequence will not follow. Now, the treatment by mercury has undoubtedly been the most successful of any as yet adopted; but in the treatment of the following case I was led to consider whether it really was necessary, so great was the relief which followed the local treatment, which consisted in constantly keeping ice in the mouth, and scarifying the swollen and œdematous epiglottis, as recommended by Marshall Hall, and by Bryant, neither of whom, however, had put it in practice. The facts of the case are as follows:—

*Case.*—John Fox, a fine little boy, two and a-half years of age, was admitted into the Adelaide Hospital upon the 16th of December, 1866, having attempted to drink boiling water from the spout of a kettle the day before at about one o'clock; fifteen minutes after he had received the scald he vomited and continued to cough all the afternoon; at about nine o'clock in the evening, for the first time, it was noticed that he was breathing with a peculiarly hoarse sound, the cough now ceased, but the hoarse breathing continued to increase in intensity all night; he did not sleep at all, but was extremely restless and very hot. When admitted to the hospital the next day he was in the following condition: his face, lips, and hands were decidedly of a bluish colour, his respiration very hurried, being fifty-two in the minute, and accompanied by a loud raucous sound, evidently proceeding from the rima glottidis; the mouth could not be satisfactorily examined, but as far as could be ascertained the soft palate and pharynx appeared covered with a greyish slough; upon applying the ear to the chest we found that the air was freely entering to the lungs, and as yet there were no bronchitic râles to be heard; pulse very rapid; skin hot; a little milk had been taken occasionally since the accident.

The treatment adopted was ice constantly kept to the mouth, and half a grain of calomel and half a grain of hippo every two hours. The ice was evidently very agreeable to the little patient, as he called for it very frequently; in fact, as fast as one piece melted in his mouth he made signs for another, and that it gave relief to the breathing was evident, for upon visiting him in two hours afterwards, before any other part of the treatment could have had time to affect him, I found his colour decidedly more natural, and his voice clearer when he speaks.

At eight o'clock in the evening the dyspnoea had increased again; respiration fifty-four; passing my finger back into the pharynx I felt the epiglottis standing up, greatly swollen, it felt like a cherry from its smoothness and roundness. Conceiving that this swelling was œdematous, and that a few scratches through the mucous membrane allowing the escape of the fluid from the submucous tissue would be of service, by removing the swelling round the opening of the glottis, I endeavoured to effect this by means of a bistoury with the point only exposed, and this carefully protected by my forefinger until it reached the epiglottis. The mouth of the little patient was kept open by means of a cork between the teeth; still although I had very good assistance I found this a difficult proceeding; at length after several ineffectual attempts I succeeded in giving the epiglottis one or two scratches; which was followed by sensible relief to the symptoms.

The ice was constantly demanded and supplied. The

calomel was continued every hour during the night, and mustard poultices were applied over both surfaces of the chest.

December 17th, ten o'clock A.M. Respirations thirty-six in the minute; much less lividity of colour; bowels were acted on in the night; the child speaks well, and asks for what it wants; has drank milk freely. Calomel continued every two hours, ice as before. Nine o'clock P.M. Slept well during the day, no purging; respirations free in both lungs; less stridor; medicine continued through the night.

December 18th. Slept well during the night; the powder was now discontinued; the bowels having acted once during the night, there was a marked change for the better in the appearance of the child; respiration still thirty; there was a considerable dribbling of saliva from the mouth, but I was not satisfied whether this was the result of the mercury or of the burn. From this time the child gradually recovered, remaining for some days very weak, and taking food with difficulty. Bronchitic râles were audible in both lungs upon the third day, and the child continued to cough for a fortnight.

There will be difference of opinion in this case as to whether the mercury administered was absolutely necessary, seeing that the local treatment gave sensible relief to the most urgent symptoms. All will agree, however, that if the effects of this accident could be safely met by such local treatment as I have described, it would be better than subjecting our little patients to so very active a mercurial treatment.

It was my colleague Mr. Richardson who suggested to me the use of ice, the marked and decidedly good effect of which was manifest to all who was watching the case. I would strongly recommend its use in all such cases. The idea of scarifying the swollen œdematous epiglottis has occurred to several surgeons, being first suggested, I believe, by the late Marshall Hall, and it appears reasonable to conclude, if the whole of the mucous membranes covering the glottis and epiglottis is raised up by submucous effusion, that two or three incisions into the epiglottis will relieve the entire swelling, by allowing the escape of the effused fluid from the submucous tissue, which is continuous all round the opening of the glottis. There is, however, a decided difficulty in the smallness of the child's mouth, and the necessity of guarding the scarificator as it passes through the mouth in attempting to perform this little operation—so great, indeed, were the difficulties I experienced, that I almost abandoned the attempt as hopeless—to meet this difficulty, and to enable this proceeding to be more satisfactorily accomplished in another case, I have devised an instrument, which I will now exhibit and explain.

Dr. Barton then drew the attention of the Society to an instrument for scarifying the epiglottis, which he had had con-

structed by Messrs. Thompson and O'Neill. It would be seen that it consists of a lancet concealed in a sheath, the latter being welded to a ring to enable us securely and certainly to carry the sheathed lancet to the epiglottis. To protrude the lancet when over the epiglottis it is merely necessary to press the little handle, when the scarification can be safely and easily performed.

Dr. BUTCHER stated that, with regard to the instrument brought under their notice by Dr. Barton, I think it likely to be an exceedingly useful one. Not very long ago a case came under my observation, and the great difficulty felt was that referred to by Dr. Barton. It is a great convenience to have an instrument that can be conducted by one index finger without injuring any portion of the mouth, or requiring the use of a second finger. I am sure that if I get a case of the sort I shall be happy to give it a trial.

The proceedings then terminated.

## MEDICAL GLEANINGS.

(From the British and Foreign Medico-Chirurgical Review.)

### PELVIC MEASUREMENTS IN DIFFERENT RACES OF MANKIND.

By Dr. CARL MARTIN.

DR. CARL MARTIN, son of the eminent professor at Berlin, fills up in a memoir rich in observations and research a void in obstetric literature. Having lived two years in Brazil, he availed himself of his opportunities to measure the pelvis of living examples of several races; he has subsequently examined and measured the dried pelvis of many European collections, and he has also made comparative measurements of fifty living women in Berlin, of twenty subjects in the dissecting-room, and in sixteen of these last he has measured again the pelvis after drying. Between January, 1860, and the middle of 1864, his observations included 800 cases.

He arrives at the following conclusions:—1. The pelvis of the European woman is the most roomy. The great pelvis is broader than in any other race, showing the greatest distance between the anterior superior spines of the ilia, and also between the crista. The inlet is naturally transversely oval, the true conjugate diameter being smaller compared with the oblique and transverse diameters. The *ala* of the *ossa innominata* are mostly translucent.

2. The pelvis of the negress is smaller, and especially narrower; its inlet is also transversely oval, but the true conjugate, like all its longitudinal measurements, are relatively greater than in European pelvises. The sacrum is broad and long. The obturator foramina are small. The *ala* of the *ossa innominata* are mostly opaque.

3. The pelvis of the Bushman corresponds to the small stature of the entire body, and is smaller than in any other race. The *ala* of the *ossa innominata* were, in all the specimens examined, opaque. The ischia were, in proportion to the length of the crista of the ilia, pretty long, and higher than in any other race. The inlet is sometimes in a high degree oval in antero-posterior direction.

4. The pelvis of the Malayan of Java and the neighbouring islands is also narrow; it shows a small distance of the spines and crests in relation to the rather large conjugate. The true conjugate is very long; the inlet of the pelvis is therefore very round, and in many specimens even oval antero-posteriorly. The *ala* of the *ossa innominata* in all Java pelvises show large translucent spots. The ischia are relatively smallest.

5. The pelvis of the aboriginal of America is, according to the few specimens examined, on an average, little smaller than the European; the inlet is round, the outlet large, and the ischia long.

6. The pelvis of the Pelasgian and Australian negresses shows a rather large distance between the spines and crests; a large true conjugate, a small transverse and a moderate oblique diameter, and thus a somewhat round inlet.

Of other races and families, Dr. C. Martin has not obtained measurements. The memoir is also deficient in information as to the comparative characters of the foetal factor in parturition. Dr. C. Martin says that he has not learned either from his transatlantic practice or his reading whether the remarkable variations in the form of the pelvis influences the mechanism of labour, especially whether the approach to the antero-posterior oval inlet brings the sagittal suture more into relation with the conjugate diameter. The coloured women in Brazil had labours neither easier nor more severe than European women. The plausible theory of Vrolik—that Javanese women bear easily children begotten by Javanese fathers, but not so those begotten by white men—is contradicted by the experience of Lehmann in Amsterdam, who often observed that Javanese servant-girls had easy labours.—*Monatsschr. für. Geburtsk.*, July, 1866.

### PERITONITIS, CONSEQUENT UPON PURULENT INFLAMMATION OF THE FALLOPIAN TUBE, INDEPENDENT OF CHILDBED.

By Dr. v. DESSAUER.

THE author refers to the accounts given of this mode of origin of peritonitis for Förster and others. (The earliest case in which this connection was clearly traced, however, was described many years ago by Sir Benjamin Brodie.—R. B.) The following is Dr. Dessauer's case:—A woman had been married twenty years without pregnancy. After marriage she began

to suffer from pelvic inflammation. In the last attack there was considerable meteoric distension and pain, preventing minute exploration. She died in a few days. Much fluid serum was found in the abdomen. Exsudations bound the intestines together. A considerable quantity of yellow creamy pus welled up out of Douglas' space. Both Fallopian tubes were much distended, a dilatation as large as a hen's egg being formed in the middle of the right one. The left tube, at the point of greatest distension, was ulcerated and perforated; the borders of the perforation was as if torn, not round, pus flowed out. The cavity of the tube was divided off into numerous spaces, forming small and larger cysts.—*Monatsschr. f. Geburtsk.*, Jan., 1866.

#### INVERSION OF THE UTERUS AFTER LABOUR.

By Dr. G. MOLLER, of Hamburg.

A SINGLE woman had just been delivered rapidly and easily of a living child—her first. When seen she was very anæmic. The midwife reported that the placenta was expelled immediately after the child, and that when feeling through the abdominal walls for the fundus uteri she found it contracted; that the patient then suddenly complained of pain, and exclaimed that something had come away from her. The womb was found completely inverted; patient in collapse. The womb was quickly replaced by grasping with both hands and pressure in the pelvic axis. Death followed in a few hours; it was attributed to shock. There was no autopsy.—*Monatsschr. f. Geburtsk.*, June, 1866.

#### COMPLETE INVERSION OF THE UTERUS, AND SEPARATION OF IT BY GANGRENE.

By E. CLEMENSEN.

A WOMAN, æt. 50, was admitted in the Frederick's Hospital, in July, 1865. She had, with an interval of four years, borne two children, the last thirteen years before. Both labours were easy. Some eight years ago she observed that the uterus prolapsed; menstruation, regular, but scanty, had ceased during the last six months. A month ago a profuse hæmorrhage took place, attended by sacral pains. The uterus was found between the thighs, the size of two fists, completely inverted. In several spots lacerations were observed, extending into the muscular tissue. Some days later the uterus seemed diminished in size; irritative fever set in; gangrene showed itself in the left side of the uterus. The uterus contracted more and more. At last only the orifice remained, as a scar. The woman recovered. The author attributes the origin of the inversion to the altered texture of the organ, resulting from fatty regression after labour.—*Hospital Tidende*, 1865.

#### ON INVERSION OF THE UTERUS AFTER DELIVERY.

By Dr. DENHAM.

A WOMAN, æt. 23, admitted five weeks after delivery of her first child. Expulsion stage rapid. Placenta forcibly extracted by the midwife ten minutes after birth of child, by traction on the cord and pressure on the fundus of the uterus. Patient suffered much pain during this operation, but suddenly got relief by the expulsion of a large tumour, which led her to exclaim, "Am I going to have another?" A continual hæmorrhage went on until admission, when she was much prostrated and anæmic. Her strength being somewhat restored by diet and medicine, an attempt at reduction was made, unsuccessfully at the time, but three days afterwards the fundus spontaneously returned. A profuse purulent discharge took place for several days. She perfectly recovered.—*Dub. Quart. Journ. of Med. Sc.*, Aug., 1866.

### Reviews.

CATALOGUE AND REPORT OF OBSTETRICAL AND OTHER INSTRUMENTS, exhibited at the Conversazione of the Obstetrical Society of London, March 28, 1866. With numerous Illustrations. London: Longmans. 1867.

THE extensive and really extraordinary exhibition of obstetrical instruments held last year, by permission, at the College of Physicians of London, will not soon be forgotten by those who witnessed it, and the Council of the Obstetrical Society have

rendered a great and permanent service to the medical profession by thus presenting, in a collected form, a catalogue of the different instruments, with illustrations of their shape and construction and, a concise description of their mechanism and uses. The work is very elegantly got up, and reflects equal credit on the editor, whose name is not announced, and the draughtsmen who have given such excellent representations of the several instruments and apparatus exhibited.

VIVISECTION; is it Necessary or Justifiable? Being two Prize Essays published by the Royal Society for the Prevention of Cruelty to Animals. Pp. 112. London: Hardwicke. 1866.

THE Society for the Prevention of Cruelty to Animals having offered a prize of fifty pounds for the best essay on the merits and demerits of vivisection, the prize was awarded to Mr. Fleming, Veterinary Surgeon in the Hussars; but as the essay of Dr. Markham was considered of nearly equal merit, a second prize was awarded to that gentleman, and the two essays are now published together. They both contain a very good abstract of the circumstances under which vivisection is justifiable, and of the limits which ought to be drawn in performing experiments on living animals.

#### THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE. No. LXXXV. February, 1867.

THE present number of our able contemporary is fully equal to its predecessors, and it cannot fail to please a variety of readers from the fact that the original communications, which are eleven in number, embrace very different and various questions. To those whose chief interest lies in operative surgery, the illustrated papers of Mr. Collis and Mr. Porter cannot fail to prove useful. The oculist will read a good deal about the ophthalmoscope in a paper written by Mr. Wilson, whose friends will moreover find a good portrait of that gentleman on p. 39. Mr. P. C. Smyly contributes "Notes in Medicine and Surgery;" while Dr. Grimshaw favours the profession with "Sphygmographic Observations on the Pulse of Typhus," a good illustrated paper, perhaps the best in the whole number. Dr. Atthill, Mr. Denis Phelan, and Mr. Spencer Wells contribute essays of no small interest to obstetricians; Dr. Maconchy, of the County Down Infirmary, gives a paper on what we may call the special surgical practice to be met with in factories, and Professor Banks gives a paper which is not only good reading, but which is also of sound practical value. The reviews and bibliographical notices are good, and the medical miscellany is quite up to the mark.

#### THE EDINBURGH MEDICAL JOURNAL. No. CXL. February, 1867.

DR. TILBURY FOX of London opens the "Original Communications" with a paper on the Neglect of the Study of Skin Diseases in England. Dr. Scoresby-Jackson (alas! now no more) and Dr. Matthews Duncan, in effect continue their respective papers commenced in the January number; there are also medical papers by Mr. Junor of Peebles, Mr. Balfour of Leven, and Dr. Watson Campbell of Dunse; and Surgical Essays by Dr. Duncan, and by Dr. George Buchanan of Glasgow. The other departments of the *Edinburgh Medical* are also well sustained this month.

#### THE GLASGOW MEDICAL JOURNAL. New Series. February, 1867.

THIS number contains three original papers, one review, a report of the proceedings of the Glasgow Medico-Chirurgical Society, and a summary of medical intelligence. Dr. Eben. Watson contributes "Remarks on the Pathology and Treatment of the Advanced Stage of Croup." Dr. Cassells furnishes a paper "On the Normal Temperature of the Body in Infancy and Childhood;" and Dr. S. J. Moore publishes an account of "Recent Cases of Cholera at Ibrox." In Dr. Watson's essay there is, on p. 376, a drawing of a laryngeal lancet, which he occasionally uses in the treatment of cases of croup.

CLONMEL LUNATIC ASYLUM.—The Lord Lieutenant has appointed Dr. Hemphill to be Visiting Physician of the District Lunatic Asylum in Clonmel. Dr. Hemphill holds a high place in his profession, and the appointment will give general satisfaction to his professional brethren, and to the large local circle in which he is so much respected.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 13, 1867.

### THE NEW PHARMACOPŒIA.

THE British Pharmacopœia of 1867, although not yet in the hands of the Profession, may now be considered an established fact. The enormous expense incurred in the preparation and publication of the former edition, and the spectacle of the great number of copies left unsold, thus entailing a positive loss, have, no doubt, rendered the Council of Medical Education and Registration very cautious in their present venture, and have induced them to bestow the greatest care in rendering the book worthy of general acceptance. It must be admitted that the difficulties in the way of the original framers of the British Pharmacopœia were exceedingly great, and although we do not in any way profess to be in the secrets of the Council, we can perfectly understand the obstacles which must have occurred in their endeavour to reconcile the different, and often conflicting views, of the representatives of the three divisions of the British Empire, most of whom had probably strong views of their own upon many disputed points, and some were, perhaps, inclined to adhere to these views with unnecessary tenacity. Besides differences of opinion as to the best mode of preparing certain drugs, or as to the exactness of equivalent numbers, and other matters of comparatively minor importance, there are really some very serious subjects for discussion in producing a national Pharmacopœia. The efficacy of several drugs, for instance, is by many doubted altogether, while by others the same drugs are declared to be endowed with the most valuable powers in the treatment of disease; and then there are the knotty points of the metrical system of weights and measures, the division of the ounce, and the still greater difficulty of determining the merits of the new as compared with the old chemical notation. On the last point even the most distinguished chemists are not yet by any means agreed, and probably nine-tenths of the existing members of the Medical Profession are not even aware of the theoretical arguments on which the necessity for the new chemical notation is based, or by which its superiority is vindicated. Nay, even if they master the facts, and are able to follow all the reasonings, we are not sure that they will agree in the expediency of the alteration, or that they will not perhaps wish that things were left as they were before Gerhardt and Laurent promulgated their very ingenious but somewhat abstruse notions.

Such are only a few of the difficulties which the

editors of the British Pharmacopœia have had to encounter, and we can therefore readily understand the somewhat apologetic tone adopted in the preface to the new book. It informs us that some medicines not included in the former book have been introduced, but in reference to many which have ceased to be in general use, and might perhaps have been omitted, it states that they are retained because the object of the Pharmacopœia is not so much the selection as the definition of the substances prescribed by the physician. Although, therefore, we do not expect many omissions of this kind, we are glad to find that *Cocculus Indicus* and Rectified Pyroxylic Spirit are among the expurgations, and we never could understand why they were introduced in the former edition.

The arrangement of the substances is different from that adopted in the last edition, and we now find that all the drugs, whether simple or compound, are placed in alphabetical order in the first part, in accordance with the plan adopted in several foreign Pharmacopœias. The object of this plan is to facilitate reference, and to prevent the inconvenience of looking for the same substance in different parts of the book. A most important feature has also for the first time been introduced—namely, a description of the doses of all the more important drugs, the quantities indicated being, as we are informed in the preface, intended to represent average doses in ordinary cases for adults. These doses are not authoritatively enjoined by the Council, and the practitioner is warned that he must rely on his own judgment, and act on his own responsibility in graduating the doses of each drug. As far as we can judge, the doses mentioned in the book are unobjectionable, and although there is nothing homœopathic in the small doses, nor heroic in the large ones, a pretty wide range is usually allowed for the exercise of the practitioner's discretion. As instances of the manner in which this new feature has been treated, we may take at random, for instance, the Dilute Sulphuric Acid, dose from five to thirty minims; *Æther*, dose from twenty to sixty minims; Aloes, two to six grains; and Tartar Emetic, as a diaphoretic, one-sixteenth to one-fourth of a grain, as an emetic one to two grains, as a contra-stimulant five to ten grains in half an ounce of water. In this last case, it will be observed, there is a very remarkable, and yet a very justifiable latitude, and a similar, though by no means so extensive a range, at least upwards, is allowed in the case of arsenious acid, the dose being stated at from one-sixtieth to one-twelfth of a grain. We repeat that the doses appear to us to be well-defined, and that the quantities indicated, while allowing quite sufficient range for individual judgment, are such as to satisfy any reasonable practitioner of the healing art.

No alteration has been made in the weights and measures directed to be employed in the edition of 1864. The ounce is still divided into 437.5 grains, and the intermediate divisions into scruples and drachms is abolished. The absence of such intermediate quantities is to be regretted, as is also the fact that the ounce is not a simple multiple of the grain; but the arrangement is unavoidable, as the avoirdupois ounce and pound are the weights practically used in the sale of medicines.

### RELIGIOUS TESTS AND MEDICAL TEACHING.

ON the 8th inst., Mr. LAWSON, M.P., obtained leave from the House of Commons to bring in a bill to open the Professorships of Anatomy and Chirurgery, Chemistry, and Botany, in the University of Dublin to all persons, irrespective of their religion. It will be in the recollection of our readers that lately we furnished them with full information regarding these Professorships in four leading articles on "The School of Physic in Ireland," which appeared in THE MEDICAL PRESS AND CIRCULAR from October 31 to November 21, 1866, both dates inclusive. In order to fully understand this question, it will be necessary for them to refer to these articles.

The clause of the Statute, 40 Geo. III., cap. 84, which Mr. LAWSON proposes to repeal, is contained in the 20th Section. We give that section in its integrity:

"XX. And be it enacted by the authority aforesaid, that the said Professorships of the Institutes of Medicine, of the Practice of Medicine, of the Materia Medica and Pharmacy, and of Midwifery, on the foundation of Sir Patrick Dunn, shall be open to persons of all nations professing their faith in Christ, and the said Professorships of the University of Dublin [that is to say, a Professor of Anatomy and Chirurgery, a Professor of Chemistry, and a Professor of Botany; Sec. xiii.,] to Protestants of all nations, provided they shall have taken medical degrees, or shall have obtained a license to practise from the said College of Physicians, in consequence of a *testimonium* under the seal of Trinity College, Dublin."

Although this proposal of Mr. LAWSON is nothing more than a political move to get rid of all religious tests as qualifications for offices, yet we should not regret to see his bill become law; but at the same time, if the alleged reason for the change be "liberal principles," as they are often called by those who are inclined to be more liberal at other people's expense than at their own, we do not think Mr. LAWSON goes far enough. The religious test will still remain, unless the other clause in the 20th Section be also repealed. We refer to the clause providing that the King's Professors must profess their "faith in Christ"—an enactment which, if rigidly enforced, would be really more exclusive than the extraordinary qualification, "a Protestant of all nations"—a phrase totally defiant of strict

theological or legal definition. It is a patent fact that while the King's Professor must profess his faith in our Divine Master (although the very terms are capable of most contradictory interpretations), yet the University Professor need not believe any religious dogma at all. He may *protest* against all existing religious beliefs, and although, on the one hand, he may be what is commonly called "a good Protestant," yet, on the other, he may be an English or a Geneva Protestant within the letter and spirit of the law; he may deny the whole Christian revelation, and be the means of spreading opinions which many who "profess their faith in Christ" would rightly regard as neither more nor less than infidelity.

It is plain, then, that the tests imposed by this clause are inoperative, in so far as they can effect what was designed by the framers of the Act; and it is also just that no person professing any form of religion should be excluded from a Medical Professorship because of it. We hope that the Roman Catholic University of Ireland may be able to show that all the reciprocity is not to be on one side; for, while most of the "liberal" *talk* about the exclusive nature of the Dublin University Medical Professorships is somehow or other connected with the Parliamentary supporters of the Roman Catholic University, it does not appear that a single Protestant has ever been appointed to any medical office in that institution; although neither "penal laws," nor the "oppressive spirit of the British Constitution," stand in the way of so desirable an exemplification of liberal principles.

The Board of Trinity College, Dublin, who elect the aforesaid University Professors, are singularly liberal in matters like these; especially when we remember that they are all Anglican Churchmen, and nearly all Doctors in Divinity. At this moment a gentleman who believes "that there is one God, and MAHOMET is his prophet" holds a Professorship in the University of Dublin; and such a fact cannot but contrast with the opinions of 1800, when the Board of T.C.D. limited their Professorships to Protestants, while the College of Physicians, being more liberal, extended theirs to all Christians. We must not forget that there may be something to be said on the other side of this question, and so we shall return to it again ere long. Meanwhile we suggest that opportunity should be taken of the introduction of Mr. LAWSON'S Bill to effect other amendments in the School of Physic Act; and we have ourselves proposed some in the leading articles above referred to. *Medical Press and Circular, Feb. 13, 1867.*

### HUNTER V. "THE PALL-MALL GAZETTE."

THIS case having on several occasions formed the subject of comment in this journal, it is unnecessary to again allude to the details of the trial. The *Pall-Mall Gazette* exhibits on all occasions a warm interest in the welfare of the

Medical Profession, and avails itself of very many opportunities of advocating its claims. In its raid against quacks and quackery, and in its zeal for upholding the honour and dignity of our Profession, it unfortunately laid itself open to legal action, in the defence of which it incurred considerable trouble and expense. The trial, *HUNTER v. SHARPE*, has, however, been of very great importance to the public as well as to the Profession, and has elicited judicial rulings and expositions of law most advantageous to the medical interests, and which must, no doubt, form precedents in other cases.

It is most desirable that we should present to the conductors of the *Pall-Mall Gazette* some token of our sympathy with them, and of our appreciation of their disinterested exertions in behalf of the Medical Profession, and of their spirited conduct in the defence of this action. It has been proposed to raise a subscription amongst the Irish Profession, the ultimate disposal of which shall be settled by the subscribers, and it is hoped every practitioner in Ireland will respond to this call. Subscriptions will be received by the editor, and by the Honorary Secretaries at the College of Surgeons.

## Notes on Current Topics.

**PROSPECTS OF THE SESSION.**—The anticipations we recently expressed have been formally accepted in the Queen's speech, so that unless the Government should be wrecked on the great rock of political reform, we may expect a considerable amount of sanitary legislation. The prevention of cholera and cattle plague, the extension of the provision of the Factory Acts, the protection of sick paupers in the workhouse infirmaries, and of our merchant seamen in their floating homes, are all questions in which the medical world takes a lively interest, and the prominent position already assigned to them is calculated to enlist the sympathies of all those who have devoted so much attention to the progress of social and hygienic improvements. Let us avoid the word reform in this conjuncture to express, not that we abdicate all political functions, but that a medical journal is not the place for the expression of opinion on this topic, while its influence should be constantly brought to bear in support of any measure for promoting sanitation by whomsoever proposed. Sanitary matters are not party questions, and whatever party may be in the ascendant, we sincerely trust hygiene will receive constantly increasing attention. **THE MEDICAL PRESS AND CIRCULAR** will supply its readers with full information as to such parliamentary proceedings.

**YELLOW FEVER.**—A discussion took place at the Epidemiological Society of London last week, which forcibly illustrates the opinions that have been advanced by some of our correspondents. The debate, if such it may be called, arose upon the reading of an able paper by Dr. Milroy, on "Yellow Fever in relation to the Home Population." The author evidently leaned to the doctrine of the non-contagiousness of yellow fever, at any rate in respect to its power of personal propagation, and succeeding speakers seemed all to subscribe to the same opinions. Why, then, the exaggerated fears of the public? Why are such fears enforced by the severities of the Privy Council, and that, as we have already pointed out, against

the opinion of its own medical adviser? We think, that in matters of such importance as this, the Epidemiological Society would only be doing justice to itself to use all its influence to propagate its views. The mere discussion at the meeting in London is not enough, the publication of its *proceedings* is limited; the very full abstracts of the debates on such important topics as this should be given to all the medical journals immediately after the meeting. This would, no doubt, incite a considerable amount of comment, and secure a publicity that can never be otherwise obtained.

**MEDICAL OBITUARIES.**—The profession have recently lost an unusual number of well-known members. Our obituaries recently contained the well-known names of Dr. Brinton, Dr. Marsden, and Dr. Martin, of Ventnor. This week we have to add Dr. Alexander Sunderland, who died at Brighton on the 31st ult., who was for some fifteen years physician to St. Luke's Hospital for Lunatics, London, and enjoyed a large consulting practice in mental cases; and another name equally well-known to the whole profession, that of Dr. Scoresby-Jackson, of Edinburgh, who died on the 1st inst. of fever contracted in the performance of his duties as physician at the Royal Infirmary.

So many men of mark have recently passed from amongst us, that we have been unavoidably behindhand in issuing their biographies. This defect, however, we hope shortly to remove.

**ROYAL MEDICAL BENEVOLENT COLLEGE.**—We hear with unmixed satisfaction that this valuable institution is about to receive four free Medical Scholarships at University College, tenable by such of its students as have matriculated at the University of London. The Council of University College are in this doing a wise as well as a generous action, and the originator of the proposal, who is about to devote £1000 to establish a fund for conferring a further benefit on the recipients, is setting an example that we earnestly hope may be followed by many who have the means of thus aiding the orphans of a profession which has always been the one to confer everything on a public often two exacting or two careless of the pecuniary difficulties of its benefactors.

**THE CHAIR OF MENTAL PHILOSOPHY AT UNIVERSITY COLLEGE, LONDON.**—The decision of the Council in this election to which we alluded some time ago, has been affirmed by the proprietors, but only by a majority of five (42 against 37.) Mr. Robertson is, therefore, preferred to Mr. Martineau, but assuredly the numbers show clearly that the council gave no satisfaction in rejecting the eminent Unitarian metaphysician on account of his being a preacher. It was not unnatural that the decisions of the governing body should be supported by many, and the case clearly shows how easy it is for professedly unsectarian individuals to receive and act upon their private prejudices. No doubt the College can thrive without Mr. Martineau, and he could add nothing to his laurels by obtaining the professorship. It may therefore be as well for all parties to let the matter be speedily forgotten.

**A GOOD EXAMPLE.**—The following quotation from the *Pall Mall Gazette* shows the good effects of prompt and energetic measures in case of cholera attack, which may stimulate all at home, in case of the outbreak of the disease, to use timely and vigorous means for its suppression:—

"Lieutenant H. C. Kemble, of the 2d Bengal Cavalry, has just set a noble example to his brother officers. When everybody else was dancing and supping, and attending durbars at Agra, he threw all his invitations into the waste-paper basket, and stopped with his detachment, ten miles away from all the grand doings, till he had stamped out an attack of cholera which threatened to be very serious. Mr. Kemble was escorting Lieutenant-Colonel Eden up to Agra with some 200 sabres. Cholera was reported at several stations along the road, so they turned out of the way to keep clear of it. It broke out, however, when they were near Bhurtpore, and two men died. Of course the escort was not admitted into Agra, though, having established a strict quarantine round the Bhurtpore country, they had apparently got rid of the disease. The European officers, however, and the political agents, with their clerks, &c., were allowed to come in. Suddenly news came from the residar in charge of the escort that five cases had occurred at once. Mr. Kemble sent off an official request for a doctor, and was himself in camp two hours after the message reached him, eight hours after the first seizure. He at once chose a site for a cholera hospital, burnt the ground on which the sufferers had been lying, and removed the whole camp. This he did every third or fourth day, marching always at right angles to his former course, and moving some two miles from the old position. The treatment began on the 5th of November; by the 15th the doctor declared all convalescent, and on the 20th the official report of "all well" was sent in. Mr. Kemble chose high and airy ground; he burnt heaps of leaves, all the spare grass from the lines wherever his hospital had stood; he was with the sick three or four times a day; above all, he raised the men's spirits—they were dreadfully depressed at first—by playing football with them, letting all who liked shoot over the country, giving prizes for firing from horseback at empty bottles, &c. Lieutenant-Colonel Jackson, his commander, says:—"I have seen Lieutenant Kemble behave well in a charge, but I think his conduct in this case even more commendable."

**THE RETURN OF THE CATTLE PLAGUE.**—While some members of our profession have been predicting a renewed outbreak of cholera, another epidemic of the cattle plague is actually upon us. In the same establishment, in Islington, in which the first cases occurred in July, 1865, it was last week necessary to slaughter the whole stock. Whence this singular renewal of the disease? The able Medical Officer of Health for the District attributes it to the employment of the old bricks of the last year's hospital shed, for repairing. He is firmly of opinion that to contagion alone is due the spread of the disease; and that in this instance he has demonstrated the precise focus of that contagion. The Privy Council will, no doubt, adopt the most energetic measures. Slaughter is the order of the day; but can no experiment be devised to determine the possibility of destroying the contagious matter? Nearly 53,000 healthy cattle have already been slaughtered in Great Britain to prevent the spread of a disease which, since its invasion, has attacked no less than 253,860 animals. With all the rigour employed in "stamping out" the disease, the loss represented by these figures is such, that its re-appearance may well provoke discussion as to the possibility of meeting it in any other way.

**THE SANITARY AUTHORITIES OF THE CITY.**—A more than usually animated discussion took place at the Court of Common Council, at the Guildhall, last Thursday, in consequence of Dr. Saunders having moved for a Special Committee to inquire into the sanitary condition of the dwellings of the London poor, and the precautions adopted by the Commissioners of Sewers during the late epidemic

of cholera. Our readers are aware that Dr. Saunders has already found some fault with the arrangements of the Commissioners, and on giving his complaints this substantive form, it might have been anticipated that a defence was ready. We cannot, however, commend the personality introduced into the discussion. Dr. Saunders did not deny some merit to the Commissioners, or rather their Sanitary Committee; but he maintained that their subordinate officers were not equal to the requirements of such an emergency—an opinion in which we anticipate a large number of our readers will coincide. We think the retort of the advocates of the Commissioners, as to the circumlocution of the Medical Visitors of the City of London Union, quite beside the mark. However earnest the efforts of the Sanitary Committee to remove every ground of complaint—and THE MEDICAL PRESS AND CIRCULAR has been the first to acknowledge these—if any nuisances were found by the medical visitors they were quite right to point them out, and a recapitulation of how much has been done is no reply to an assertion that something has been left undone. As we observed last week, the proposal of Dr. Saunders to employ medical men as sanitary inspectors is a simple and feasible plan. We may add that it is one likely to remove all grounds of complaint, and greatly conduce to the welfare of the public.

## Parliamentary Intelligence.

HOUSE OF COMMONS.—FEB. 5TH.

### POOR RELIEF.

COLONEL TAYLOR gave notice that on the 8th inst. Mr. Hardy would move for leave to bring in a Bill relating to asylums for sick and other poor in the metropolis, and for the distribution over the metropolis of portions of the charges for poor relief.

### THE FACTORY ACTS.

COLONEL TAYLOR gave notice that Mr. Walpole would, on Friday, the 15th inst., move for leave to bring in a bill for the extension of the Factory Acts, and also a bill for regulating the hours of labour of children, young persons, and women, employed in workshops, and for other purposes.

### THE UNIVERSITIES OF OXFORD AND CAMBRIDGE.

Mr. EWART gave notice that he would on Tuesday next ask leave to bring in a bill to open the benefits of education in the Universities of Oxford and Cambridge to students without obliging them to be members of a College or Hall in those Universities.

### FLOGGING IN THE ARMY.

Mr. OTWAY gave notice that on the motion for going into committee on the Army Estimates he should move a resolution for the abolition of flogging in the army.

Mr. M'CULLAGH TORRENS gave notice that on this day week he would bring in a Bill to make better provision for the dwellings of mechanics and labourers in large towns.

### FEB. 6TH.

### DUBLIN UNIVERSITY PROFESSORSHIPS.

Mr. LAWSON gave notice that on Friday he should move for leave to bring in a Bill to open the Professorships of Anatomy, Surgery, Chemistry, and Botany in Trinity College, Dublin, to all persons, irrespective of their religious creed.

### CAPITAL PUNISHMENT.

In answer to a question of Mr. HERBERT respecting the Bill of last year on this subject,

Mr. WALPOLE said the Bill of last year did not come down from the House of Lords till nearly the close of the

Session. The Government, exercising the best judgment upon the subject of which they were capable, thought it ought to be amended in point of form. But he could now inform his hon. friend that two Bills had been already prepared, having for their object to separate the two distinct branches of the subject—namely, that relating to crime exclusively from that relating to capital punishment. The two Bills would shortly be introduced, and hon. members would have an opportunity of considering their provisions.

FEB. 8TH.

METROPOLITAN SICK POOR.

On Friday evening last, pursuant to notice, Mr. HARDY moved for leave to bring in his Bill for the improved accommodation of the sick poor of the metropolis, pre-facing it by an elaborate review of past legislation on the subject. The chief improvements requisite were, in Mr. Hardy's opinion, greater cubical space, increased ventilation, and more complete classification of the poor; assuming that he had to deal with about 34,000 persons, including children, he proposed to obtain these improvements by placing all the imbeciles in separate establishments, by removing all children above two years to separate schools, and by providing new accommodation for 2000 lunatics, and for 700 or 800 fever and small-pox patients, either by erecting new buildings or hiring old ones. The infirmaries for the remaining sick poor would be placed under separate boards of management, for many of the evils in their condition sprang from their being managed under a system originally intended for the ordinary poor; and of these Boards one-third of the members would be nominated by the Poor-law Board from persons resident in the district or union rated at not less than £100 a-year. By this means he hoped to secure more efficient inspection, and to give facilities for training nurses and for educating medical officers. For the relief of the out-door sick he proposed to establish central dispensaries; and to require that the medical officers, instead of making up their own medicines, should, in all cases, give prescriptions. The Bill also provided that the Local Acts in the metropolis (ten in number) should be repealed, and that the whole metropolis should be placed under the Poor-law Board.

Mr. HARDY next discussed the equalization of Poor Rates, pointing out various objections to the principle, and intimating that, though he could not consent to equalize the metropolitan rates, the Bill would throw on the common fund the charges for lunatics, fever, and small-pox patients, medical officers, dispensaries, and medicines, registration, vaccination, and the maintenance of children at school. To illustrate the effect of the distribution of these charges, £60,000 in amount, he mentioned that, while it would add 3½d. in the pound to the rates of the City of London Union, it would relieve St. George's, Southwark, of 1s. in the pound, and would not amount to more than a penny rate over the whole metropolis. The last feature of the scheme—which altogether was very favourably received by the House—was a power to the Poor-law Board to appoint proper officers where the guardians refused or neglected to do it.

Mr. AYRTON, Lord ENFIELD, Dr. BRADY, Mr. LOCKE, and Alderman LUSK made some general remarks in approval of the principle of the Bill, and leave was then given to bring it in.

## Correspondence.

MR. RICHARDSON'S REPLY TO MR. HOLT.

PERREVE'S STRICTURE DILATOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Holt at the last moment admits the priority of Perrève. Thrust upon him by the force of fact and of logic, he admits this most important conclusion, and which carries

with it the still further admission that he had not the candour to name the originator in any edition of his book.

For the rest, Mr. Holt's simple denial of the facts I have proved, will be taken, after the above admission, for what that denial is worth. I have stated as fact nothing which I have not proved, earning thereby Mr. Holt's epithets of "verbose, personal, and offensive."

"Verbose," of course, because it takes longer to prove than to affirm; "personal," certainly, because addressed of necessity to Mr. Holt; "offensive," doubtless:—I can conceive few things so offensive as bringing to the light of day a want of candour and fairness; happily not often to be witnessed in our own profession.

I have laboured at some pains in behalf of truth, and I have completely fulfilled my task, and set at rest this vexed question of the origin of the instrument now employed for rupturing the urethra, I shall therefore cheerfully submit to the ill-will I must necessarily incur from those, who have been interested in suppressing the facts in question.

Mr. Holt having been driven to admit the priority of Perrève's invention, let us see what he said of this gentleman's instrument in the *Lancet* for 1852, and in which dilator of Perrève's he now finds it necessary to discover so many errors of construction.

The following extract from his statement in the *Lancet* in 1852, will clearly explain what terrible humiliation it must have been for Mr. Holt to be compelled now to refer to it:—

"I think," says he, "every object of such dilatation is attained by the following modification of M. Perrève's instrument which I have named the "Stricture Dilator."

I confess I am not being able to understand that Mr Holt was called upon to name the instrument the "Stricture Dilator," Perrève having already named it the "New Dilator."

Mr. Holt having stated in his letter of the 9th of last month that in his instrument "you have all the elements of success, while in Perrève's there are errors which have made it unsafe even in experienced hands," let us contrast with that assertion his opinion of the safety of Perrève's instrument as enunciated in 1852:—

"From the success which has attended the introduction of the instrument, and the speedy yet safe method by which the stricture can be effectually removed, I have no hesitation in affirming that if these patients had been subjected to the present plan of treatment, none of the inconveniences there encountered would have been effected in the same progressive manner as in the cases just related."

As I have already given a detailed account of Perrève's dilator, I shall here merely observe that Mr. Holt's modification of Perrève's instrument was anything but an improvement: for, while he dispensed with one of Perrève's steadying clamps, he did not substitute anything for it.

There is hardly any modification which he could possibly have devised would have answered the purpose so perfectly as the original clamps of Perrève.

The shortening of the conducting-rod was quite unimportant one way or the other.

As just shown, Mr. Holt's observations in favour of Perrève's instrument were consigned to the *Lancet* in 1852. And although there they were, ready at any moment to be brought to light, yet he had the temerity to bring forward the same dilator altogether as his own in 1861, in both the *Medical Times and Gazette* and in his memoir, totally suppressing any mention of Perrève's name in connection with it. The third line of Mr. Holt's quotation from Don Quixote—

"No fears my daring courage awe—"

is so truly applicable to such rashness that I may exclaim:—

"I thank thee . . . for teaching me that word."

It is no wonder then that I did not find Mr. Holt's acknowledgement of M. Perrève's priority as in Mr. Holt's book he refers only to his paper in the *Medical Times and Gazette*, in which paper Perrève's name is not mentioned, and he claims the instrument as his own.

An acknowledgement of Perrève's priority would have been rather awkward in a memoir published in 1861, where Mr. Holt introduces the immediate method in the following words:—"Hitherto I have not ventured to publish the plan I adopt, simply for the reason that it is injudicious to enunciate any new method of treatment which has not been subjected to numerous and repeated trials." And yet he was in possession of Perrève's scientific volume, where it is written:—"It is sufficient to see" the dilator "to be convinced that the dilatation may be as rapid as possible." And again:—"The time is near

indeed when the treatment of all urethral coarctations will be, I believe, reduced to a single application of my dilator."—*Traité des Retrecissements Organiques de L'Urètre*, a Paris, 1847. And he must also have had Civiale's work published in 1858, in which it is likewise written, where Civiale speaks of rapid or instantaneous dilatation:—

"Rapid or instantaneous dilatation from within outwards is performed according to two different methods."

"(1)" "According to the first" (Perrève's), "the instrument the surgeon selects, being passed into the urethra, the surgeon acts with energy so as to increase the contracted point from five to seven millimètres (one of the limits M. Perrève assigns). The effect is immediate, and the force employed is proportioned to the resistance of the tissues."—*Traité Pratique sur les Maladies des Organes Génito Urinaires*.

I shall now proceed to deal as succinctly as possible with the remaining paragraphs of Mr. Holt's letter *seriatim*.

The second paragraph asserts, "*vide* page 54 of my first edition. I simply claimed the credit which attached to the publication of a series of interesting cases subjected to a novel plan of treatment." That it was not novel is shown above. And here I may observe that Mr. Holt has, in one of his letters (9th January), assumed that in Perrève's method the stricture is dilated and not split, inferring thereby that splitting only occurs from his thrust of the forcer. Now it so happens that Mr. Holt has never yet, that I am aware, produced any positive evidence that when he uses the wedge in the living subject, according to what is known as the immediate method, the stricture is split at all. He has, indeed, in the second edition of his memoir, given an illustration of a stricture which it is stated was split *after death*. But this by no means proves that a similar result ensues in the living subject. On the other hand, it is altogether dogmatical assumption on his part that in Perrève's method of using the dilator, the stricture is only dilated. Such is not the opinion of Civiale who, in speaking of Perrève's treatment, says:—"The deeper the laceration of the tissues the longer is the consecutive effect sustained."—(Ibid). If I do not mistake Mr. Holt is familiar with these words of Civiale.—(Vide Mr. Holt's letter, 9th January).

"Thirdly"—Mr. Holt writes:—"I never denied the existence of a directing-rod in Perrève's instrument." I never said he did. But when he asserts "that this directing-rod, and the clamps attached to the lower half handle, will not prevent any other than the very largest tube from being thrust beyond the blades," he is greatly mistaken, and speaks what is not the fact, Perrève's clamps, directing-rod and grooved half handles being more efficacious for preventing such an accident, than any alteration Mr. Holt has made in the instrument with a similar object.

"Fourthly. The paragraph, 'in the hands of an experienced surgeon,' was necessary, for even Mr. Richardson does not know that the tube in Perrève's instrument will project in spite of the directing-rod." I fear I know a little more of the tube than is agreeable to Mr. Holt! There is some confusion, however, on his part, in this paragraph, the observation, "in the hands of an experienced surgeon," having been applied to the catheter principle of the instrument. "In the former instrument," he states in his book, "it was objected that there was no positive evidence that the instrument was in the bladder, and the objection was a valid one, although in the hands of an experienced surgeon, such a difficulty could hardly occur." "This is now remedied by having the directing-rod hollow, with an opening at the back of the curve of the dilator, so that when the stilette is removed the urine will escape in the same manner as it does when a catheter is used."

I have arrived at a deeply critical part of my answer as regards Mr. Holt, for I shall now lay before the reader, evidence that the catheter principle was applied to Perrève's dilator a couple of years before the appearance of the second edition of Mr. Holt's book, where he first claims it altogether as his own:—

"Glasgow, Jan. 30, 1867.

"SIR,—Your letters on the question—"Is the instrument, called Holt's dilator, the invention of M. Perrève or of Mr. Holt," induce me to inform you of circumstances bearing on the subject which have fallen to my experience. In April, 1856, I obtained, in Paris, a Perrève's urethra dilator with curved point (most accurately delineated, Fig. 2, in your letter). This dilator was purchased from me by the late Dr. Hunter, Professor of Surgery, Andersonian University, &c., who employed it with much satisfaction, and lent it occasionally to other surgeons from 1856 to 1864. In 1861 I made some alterations in the instrument. I perforate the extremity

or point of the dilator, that so the urine might escape and prove that the instrument was in the bladder, and supplied a movable conducting-rod slightly probed at the point, that the operator, by carefully manipulating with it, should succeed in introducing the instrument in the more difficult cases. I showed a dilator, with these additions, at the International Exhibition of 1862, and believe these alterations (or improvements, if so considered) had not previously been shown or described by any one. The handle I also modified, and gave it a shape more consistent with our ideas of a staff handle. The original Perrève's instrument obtained in 1856, and the instrument which I modified and exhibited in 1862, I think can be brought forward, if necessary, to corroborate my statement.—I am, sir, your obedient servant,

"WILLIAM B. HILLIARD,

"Instrument and Appliance Maker to the Glasgow Royal Infirmary.

"B. Wills Richardson, Esq., Dublin."

Since the above was received, I have, through the kindness of Mr. Hilliard, seen the instrument. The beak is perforated at the point, but as the conducting-rod is a movable one, it is not hollowed, and so far differs from the arrangement in the so-called Holt's dilator. The object of both gentlemen having been the same, of course Mr. Hilliard is entitled to precedence for a dilator with the catheter principle. It is curious, also, that the handle of Mr. Hilliard's dilator is identical with Mr. Holt's *new* (?) handle brought out for the first time in 1863. It being the same shape, and has no clamps, their place being supplied by *steadying pins* alone.

Mr. Hilliard was the manufacturer of surgical instruments, &c., to whom was awarded the *only* medal "given by the International Exhibition of 1862," "for excellence in the manufacture of instruments" in Scotland. His name is numbered 3530 in the official catalogue.

"Fifthly. Mr. Richardson is again in error, the details of the two instruments are entirely different, and this Mr. Richardson's laboured statement fails to disprove." I apprehend this is a question for the profession, and not for Mr. Holt, to decide, and flatter myself that I have clearly proved the two instruments are identical, with the exception of the catheter principle for the escape of urine, which I have shown is Mr. Hilliard's and not Mr. Holt's.

"Sixthly"—Mr. Holt writes—"I again affirm the instrument is equally efficacious where dilatation is desired, the sentence simply referring to the applicability of the instrument and not to the propriety of the treatment." I still maintain that the above quotation from his book is a contradiction of his assertion in his letter that he is never satisfied unless the stricture is split. He abuses Perrève's and Thompson's dilatation method in the same letter, yet he recommends it (of course without acknowledgement of its being Perrève's method) in his book, and it was the mode of procedure which effected such wonderful results in Mr. Holt's hands in 1852.

How does Mr. Holt, in his seventh paragraph, meet my statement in my letter of the 23rd January, where I say that "he," Mr. Holt, "has not adduced any evidence whatever to show that the instrument had ever been prominently brought before the notice of the profession, or even used in the United Kingdom, and has not detailed one single well authenticated case of serious injury from a dilator constructed as Perrève directed."

"My information," says Mr. Holt, "respecting the abandonment of Perrève's instrument was derived from foreign surgeons who have witnessed my operations at the Westminster Hospital"!!

As we have no data to show that Perrève's instrument was ever prominently brought before the profession in the United Kingdom, possibly it was from foreign surgeons, likewise, that Mr. Smyly received the information that Perrève's dilator was "completely rejected as dangerous," "by the first practitioners both in England and this country," as he so positively asserts in his letters on the 21st November and 9th January!

"Lastly," Mr. Holt writes—"My endeavours have been exercised to produce an instrument so simple that it can be used by all members of our profession, and however it may annoy Mr. Richardson, I am happy I have succeeded." Mr. Holt very ingeniously has here introduced another matter altogether foreign to my argument. He is as well aware as I am, that when I spoke of "in the hands of an experienced surgeon," it was in reference to his assertion in his book that in the hands of an experienced surgeon the catheter principle is not necessary, and therefore that he must think the Perrève's dilator a

perfectly safe instrument in similar hands, although it is not provided with an exit for the urine.

As no other practical alteration has been made in the Perrève dilator, it is a contradiction, on Mr. Holt's part, now to say that it has errors of construction which have made its use unsafe *even in experienced hands!*

"It is rather late after six years," says Mr. Holt, "to endeavour to prove the identity of the two instruments!" Surely Mr. Holt cannot for a moment imagine that the profession will allow him to take advantage of the six-year statute of limitations in this matter. It would be a *legal* defence to a tailor's bill I admit, but must not debar Perrève of the right to that justice to which he is entitled under the code of honour.

I may again assure Mr. Holt that this controversy was forced upon me by Mr. Philip Smyly, who accused me in a letter, published in this journal on the 21st November, of "misstatement" in attributing the invention of the dilator to Perrève. And if, in my refutation of Mr. Smyly's offensive term, I have clearly shown that the profession does not "owe" the instrument "entirely" to Mr. Holt, which Mr. Holt, has been now compelled to admit, he has no one to blame but Mr. Smyly.

I am at a loss for Mr. Holt's meaning, when he says that I am "more desirous of quarrelling with "my colleague," than I am "of defending my friend." Mr. Smyly is not my colleague, but whether he is or not I have no wish to quarrel with him or any one else. If he implies that Perrève is my friend he is mistaken, as the only interest I have in this matter is the cause of truth, forced upon me to maintain for the reasons I have above stated. I believe Perrève is dead. His dilator remains. Mr. Holt used it as Perrève's in 1852, and ever since that year has published and used it solely as his own invention.

Again, Mr. Holt's assertion—"So long as Mr. Richardson's patients have no objection to his preference for Perrève's instrument, I am sure I have not," comes with something like *ingratitude* from one who has been using it for so many years!

"Ingratum si dixeris omnia dicis."

And now I ask my readers what has been left to connect Mr. Holt's name with the dilator? Simply the few inches Mr. Holt cut off from Perrève's conducting rod! I do not grudge him this piece of wire. He may have it with all my heart. And in conclusion, I would recommend Mr. Holt, before he again writes a book, to read over the following dialogue from *Le Sage*, which took place between Asmodeus and Don Cleophas, during one of their aerial flights, and while they were looking down into the attic of the Marquis:—

"This author, then," replied Don Cleophas, "is a man of some note." "You are to judge of that yourself," answered *Le Diable*; "he is surrounded by a thousand volumes, and is compiling one in which there will not be a line of his own. He abstracts from all those books and manuscripts, and, though he only methodizes and connects his appropriations, yet he has a larger share of vanity than a real author."—I have the honour to remain, sir, your very obedient servant,

B. WILLS RICHARDSON.

#### AMENDMENT OF THE MEDICAL CHARITIES IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—When the "Tories" were in office a few years ago, Lord Naas, who was then, as well as now, the Chief Secretary for Ireland, introduced before the House of Commons an "Amended Medical Charities Bill," which contained some important clauses of improvements on the present unsatisfactory system. Deputations from the Irish Medical Association, including its tributary branches, waited on his lordship, suggesting some modifications, which were to be discussed before a "Select Parliamentary Committee," but the existing government having soon after retired from office, the measure was left in abeyance; under these circumstances, it seems strange to some why no active steps have been taken lately by the "Medical Protective Association," to urge on the Chief Secretary the necessity of preparing some measure to ameliorate the position of the Dispensary Medical Officers, many of whom labour under severe grievances. More than a year has already elapsed since a large meeting of the profession was convened at the Limerick Junction, in order to take into consideration the means of redressing the wrongs under which we labour, but though a considerable amount of enthusiasm and sympathy then seemed to be manifested, it is to be feared that a sort of indifference has since crept in among even zealous

members, as may be surmised from the fact that we no longer hear of any public demonstrations of the same kind, with the exception of an important deputation from Sligo, to the "Chief Secretary," and which, strange to say, has not been followed by others of a similar nature. It now appears to be finally decided that the moiety of the salaries of the dispensary doctors is to be paid out of the Consolidated Fund, a desideratum long wished for, not only by Boards of Guardians, but also by the Medical Officers at large, as being likely to be fraught with strong advantages to their positions. While, as a general rule, it is to be hoped that this may prove true as regards many Poor-law Unions, still it is to be feared that exceptional cases will arise wherein Boards of Guardians, notwithstanding the reduction of taxation, will be not a whit more desirous to consult for the welfare of their medical officers, so great is their sordid spirit of economy. In the County of Cork, within the last few years, the salaries have been considerably raised, in the vast majority of the unions, even to the extent of £100 per annum; but in the union to which I have had the *good fortune* to be connected with, all attempts on the part of the dispensary physicians to have their salaries raised above the standard of £70 a-year, have been met with ungenerous opposition, and I have reason to believe, that under the *new regime* the feelings of several of these *soi disant* guardians of humanity would not be much altered for the better. In order, therefore, that the contemplated transfer of half the salaries to the Consolidated Fund shall be regarded as a general boon to the profession connected with the poor-law, experience and a sense of equity point out the necessity of investing some central governing body with the powers of regulating the standard of salaries and withdrawing them from local boards, and that a golden opportunity will be soon at hand for coming to some arrangement of the kind may be possible before the Chancellor of the Exchequer is about to explain the estimates connected with his "Budget." Would it not be highly expedient, therefore, that meetings of the Medical Association be immediately commenced in order to take active steps to urge on the Legislature the necessity of effecting some changes in the administration of the "Medical Charities Act," so loudly called for, not only in the interests of the dispensary doctors, but also those of the sick poor. Deputations should wait not only on the Chief Secretary, but memorials signed by the body of the Poor-law Medical Officers, numbering nearly 800, should be forwarded to both Houses of Parliament, praying for some measure of redress for their grievances. If the present government, however, should show no friendly disposition to yield to our representations, then it would behove us at the next election (which, in the opinion of sagacious observers, is not remote) to use our influence against the return of any candidates who would not pledge themselves to espouse our cause, irrespective of political parties. As agitation is now a powerful engine of success in this unsettled age, why should the medical profession stand exceptional to other social bodies of the state, in not making strong efforts to obtain justice and equality.—Yours truly,

A DISPENSARY PHYSICIAN.

#### HEALTH RESORTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In last week's number of THE MEDICAL PRESS AND CIRCULAR, I observe a letter on the subject of health resorts, signed "One who has Ceased to be a Wanderer." The writer of this letter states that his remarks on the effects of change of climate are the result of his experience of several successive winters passed on the Riviera, between Marseilles and Genoa, and he sums up the conclusions he has arrived at by that experience in the following words:—

"On the whole, I give it as my opinion, judging from experience, that if the people would make up their minds to stay quietly at home, keep their houses warm and dry, and not go out in bad and treacherous weather, they would be quite as well in their own country. . . . It would be well if this fashionable mania, which invariably engenders a restless spirit, satisfied with nothing and contented nowhere, could be put an end to. People would then find out that they are as safe by their own fireside as elsewhere, and that they are able to enjoy the comforts that no other country can afford. . . . In fact, if so disposed, there are several nicely-sheltered places in England, where they might very advantageously and safely pass the winter months without the fatigue, and in many respects the inconvenience, of going abroad."

As this letter appears to me calculated to do harm, by de-

preciating the value of one of the most important therapeutic agents that can be employed by a physician in the treatment of some of the most serious chronic diseases for which medical advice is sought, may I request you will allow me space for a few remarks in reply to it.

Your correspondent, "One who has Ceased to be a Wanderer," claims for himself extensive "personal knowledge and observation" on the subject of change of climate, and therefore, before replying to his observations, I may also claim for myself some share of that personal experience which he boasts of. I, too, have studied change of climate practically, not merely, as your correspondent appears to have done, "at different places along the Riviera," but in Southern Spain and Portugal, France, Italy, Algeria, and Egypt, to the health resorts of which countries I have in several cases made repeated visits, and in others have resided during the winter. The results of that experience have led me to very different conclusions from those of "One who has Ceased to be a Wanderer." I would go so far as to state that, in the treatment of certain intractable chronic ailments, there is no single remedy of equal efficacy with a judicious change of climate; that is, change to a climate suited for the special exigencies of the disease we have to treat, and this change must be assisted by other appropriate remedies. The diseases which my experience of the various parts of Europe and Africa that are resorted to by invalids from these islands in winter, convinces me we may derive benefit from change of air are numerous. They include nearly all chronic pulmonary diseases, especially phthisis, chronic bronchitis, laryngitis, asthma, both humoral and dry, chronic rheumatism, dyspepsia, hypochondriases, and many other chronic complaints. It must be obvious that diseases so different from each other must require treatment as different; and this variety of treatment by change of climate may be obtained in the various southern winter resorts, frequented by invalids, each of which presents some peculiarity of climate by which it may be distinguished from other places of the same kind. Moreover, the different forms and stages of the same disease often require climates as different as though they were distinct maladies.

These very obvious principles of medical climatology are altogether ignored by "One who has Ceased to Wander," for he uses the term health resort as though it were a specific term, employed always to express the same thing. I fully agree with what your correspondent says about the climate of Mentone, but may observe that in my work "On Change of Climate," pp. 306-310, and in my essay "On the Climate of Malaga in the Treatment of Chronic Pulmonary Diseases," p. 5, which were published, the first in 1864 and the second a year later, I pointed out very fully the disadvantages of the climate of Mentone as a winter residence for pulmonary invalids, which "One who has Ceased to Wander" has since discovered.

The subject of the remedial influence of change of climate is a very large question, and neither your space nor my leisure allow of its discussion at present. But, as the evident tendency of the letter of "One who has Ceased to Wander" is to decry the efficacy of changes of climate in cases of pulmonary consumption, a few practical remarks on this point may be of some interest to those who have read your correspondent's letter.

Of all the remedial measures which I have seen employed in the treatment of phthisis, the two from which I have known most benefit derived were cod liver oil and change of climate. My observations here are confined to the latter of these. There are two leading varieties of phthisis, and these require very different climates. In the first and most frequent our patients are persons of a relaxed, anemic, and scrofulous constitution, who complain of profuse expectoration, cough, and colliquative sweating and diarrhoea. This class of consumptive invalids require what is described as a "tonic winter climate;" that is to say, a winter resort, the atmosphere of which is warm, dry, bracing, and not subject to great or sudden variations either of temperature, pressure, or force of the wind. The principal climates of this kind which I have visited are Egypt, especially the upper part of Middle Egypt, Western Australia, Nice, and Hyères, the Mediterranean, Coast of Spain, and most especially *Malaga*, where I prefer to send the majority of those who require a climate of this class. Indeed, I have every reason to speak highly of the climate of *Malaga*, both from my own experience and that of patients whom I have sent there.

The second form of consumption to which I have alluded is less frequent than the first. Its characteristic features are dry, hard frequent cough, hæmoptysis, quick thready pulse, and slight expectoration. Cases marked by these symptoms

require a sedative climate; that is, a climate the principal points of which are a humid, warm, and somewhat relaxing atmosphere. The principal climates of this class which I am acquainted with, are Pisa, Madeira, and Rome. Algiers, where I passed a great portion of one winter, holds, I think, a position between the two classes of climate I have described. Each of these climates has its special advantages in some cases in which any other climate might probably be more injurious than beneficial.

I need hardly add that the earlier in the course of the disease a consumptive patient is sent to a suitable climate the greater is the probability of his recovery; but even when the disease had advanced so far that the patient presented all the physical signs as well as the symptoms of a small cavity, I have seen the progress of the disease apparently arrested for a time, and have known a great improvement in the patient's general health and strength result from a suitable change of air. In such cases, however, the improvement was often very transitory, and the disease again resumed its progress. No one can be more impressed with a feeling of the cruelty of sending a patient far advanced in the third stage of phthisis abroad, for it has too often fallen to my lot to attend consumptive invalids in *Malaga* and elsewhere, who had been sent abroad either too late or to an unsuitable climate.

"One who has Ceased to be a Wanderer" speaks of change of climate to foreign winter resorts as "a fashionable mania which invariably engenders a restless spirit, satisfied with nothing and contented nowhere." This I am sure a little reflection will convince your correspondent is a hardly deserved manner of speaking of a remedy which is chiefly resorted to as a last resource by those who have little other hope of recovery from a disease, the victims of which are so frequently the young, the beautiful, and the intellectual.

With regard to the comparative merits of British and foreign winter resorts, it would be easy to answer the arguments of your correspondent, but I have trespassed already longer on your space than I should have done were it not for the importance of the question at issue.—I am, sir, your obedient servant,

THOMAS MORE MADDEN, M.R.C.S.Eng., L.K.Q.C.P.I.

#### LONDON SURGICAL HOME.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am directed by the two senior surgeons, Mr. Baker Brown and Mr. Philip Harper to state that, *solely* in deference to the opinion of THE MEDICAL PRESS on the subject of clitoridectomy, they have determined not to perform the operation in this institution pending professional inquiry into its validity as a scientific and justifiable operation. An early insertion of this note in your journal will oblige your obedient servant,

WOLLASTON F. PYM, Secretary.

#### THE WEATHER AND THE PUBLIC HEALTH.

(From the Registrar-General's Returns.)

THE deaths registered in London during the week ending Feb. 2nd, were 1628. It was the fifth week of the year, and the average number of deaths for that week is, with a correction for increase of population, 1600. The deaths in the present return exceed the estimated number by 28.

The deaths have fallen from 1180 in the previous week to 1628, as the weather has grown milder, and now we have fortunately passed the coldest month of the year. The reduction in the number of deaths as winter has relented is visible at every period, except the last age of all (30 to 100 years), at which 100 deaths were recorded.

The diseases of the lungs grew frequent and fatal, but have now declined. Thus the deaths from bronchitis in the six weeks were at first 224 and 178, then, as the effects of severe frost accumulated, 375, 308, and 399, falling down finally this week to 271.

No death from cholera has been registered for a fortnight but the deaths from diarrhoea have increased. While the epidemic of scarlatina is declining small-pox is increasing, and last week 55 persons died of the disease in London—22 in the north (where the Small-pox Hospital is situate), 13 in the east, and 16 in the south districts.

The deaths returned last week in London and in twelve other large towns of the United Kingdom furnishing returns showed a decrease of 586, upon those of the previous week; of this decrease 252 occurred in London, 107 in Liverpool, 110 in

Manchester, and 63 in Glasgow. In Dublin alone was shown a further considerable increase upon recent weeks; the 286 deaths exceeded by 129 the corrected average weekly number, and included 102 fatal cases of bronchitis.

The annual rate of mortality last week was 21 per 1000 in London, 30 in Edinburgh, and 47 in Dublin; 31 in Bristol, 26 in Birmingham, 30 in Liverpool, 32 in Manchester, 31 in Salford, 29 in Sheffield, 32 in Leeds, 30 in Hull, 32 in Newcastle-upon-Tyne, and 35 in Glasgow. The rate in Vienna was 27 per 1000 during the week ending the 26th ult., when the mean temperature was 11.1° Fahrenheit lower than in the same week in London, where the rate was 32.

### SOUTH DUBLIN UNION.

Sir ROBERT SHAW, Bart., in the chair.

A report was brought up from the finance committee recommending that remuneration should be given to the medical officers of the South City Dispensary Medical Staff, at the rate of one guinea per night for each night's duty performed by them during the prevalence of cholera.

Alderman Bonsall had no objection to the proposed remuneration to the medical officers, with the exception of two of them, who persistently set the order of the Board at defiance, and refused to sleep in their turn at the dispensary.

Mr. Byrne explained that the law did not compel the medical officers to sleep at the dispensary. The two gentlemen alluded to by Alderman Bonsall performed all the duties well and efficiently, and in some cases their remaining at their own residences was an advantage to the public, who very soon learned that these medical gentlemen were to be found in their own houses. He (Mr. Byrne) would certainly not vote for withholding the remuneration from the gentlemen in question, both of whom had performed their duty efficiently and well.

Dr. Owens hoped that this would be a lesson to the Board not to make rules which the law did not enable them to enforce.

Mr. Macready was decidedly in favour of not now making a difference between the medical officers. It was when the rule was violated that the two doctors should be held amenable, and not now when an interval so long had elapsed.

Alderman Bonsall moved his proposed amendment against paying the two gentlemen in question the proposed remuneration.

The amendment having been lost, Mr. Guinness moved that the two gentlemen should only get fifteen shillings per night for their attendance, which was carried.

A gratuity of £30 was ordered to Dr. Grant for his services during the prevalence of cholera, as resident apothecary of the workhouse. Several other gratuities to the house officers were also ordered in various small sums.

The Board, having transacted the routine business, then adjourned.

### LONDON FEVER HOSPITAL.

On Friday last the annual meeting of the Governors of this Institution was held, and the report presented. It appears that the number of patients admitted last year, 3577 was greater, with one exception, than in any year since the foundation of the hospital, and during the last five years the number admitted has been 15,351, or nearly one-half as many as during the previous 60 years. Of the 3577 patients admitted during the year, 2897 were suffering from true specific fevers, and 90 from cholera, while in 590 the febrile symptoms were the result of local disease. The fevers treated in the hospital besides other acute diseases, cholera and smallpox (59 with the latter disease admitted because the Smallpox Hospital was full), were typhus, enteric, scarlet, measles, and simple febricula. Typhus, the fever the prevalence of which is connected with overcrowding and destitution, had prevailed to an unprecedented extent during the last five years; but last year the numbers

with this fever were less than in 1864. A large proportion of those admitted with typhus had been out of employment and in a very destitute state for a long time prior to the attack, and the localities from which they were mainly brought were the poorest and most overcrowded. Of the 1735 typhus patients, St. Pancras sent 232; Bethnal-green, 176; Whitechapel, 156; and St. Luke's (Old-street), 156. One fact was shown, with regard to this epidemic—namely, that during this year it was more generally distributed throughout the metropolis than when it commenced in 1861. The enteric fever an endemic rather than an epidemic disease, due, it was believed, to bad drainage, had risen during 1865 and 1866 from an average of 181 to 520 and 575, an increase which was ascribed in a great measure to certain climatic influences. Of the 3577 admitted during the year, 2890 had been discharged recovered, 55 had been sent to other hospitals, and 658 had died. This high death-rate was explained to be owing to the fact that a great many patients were sent to the hospital in a dying state. The committee had sold out a third of its small funded property in order to erect a new wing, and by doing this no case of fever had been turned from its doors during the last three years. Five of the attendants had died—four nurses and the resident medical officer—through fever contracted while at their duty. Mr. Taverner moved the adoption of the report, and said he thought if the great work the hospital performed were generally known, the inhabitants of London would not rest contented with allowing its list of annual subscriptions to amount to only £600, especially when a guinea a-year was all the payment required to constitute a governor. Dr. Jeafferson seconded the adoption of the report, which was carried, and a vote of thanks, moved by Mr. Low, and seconded by the Rev. C. C. Collins, was carried to Dr. Murchison for the report. On the motion of Mr. Hugh Owen, of the Poor-law Board, the Earl of Devon was re-elected President, and the other officers were also re-elected. Votes of thanks were given to Mr. Owen, for acting as hon. secretary; to the chairman, and to Mr. Robinson, a member of the committee.

### Medical News.

THE Prince of Wales is to be invited to act as President of St. Bartholomew's Hospital.

A ROYAL decree has been issued from Brussels provisionally prohibiting fairs and markets for cattle of all kinds.

CATTLE PLAGUE.—One attack of cattle plague is reported during the week ending January 26th, being a decrease of ten on the previous return. This was a fresh outbreak of the disease, and occurred on a farm in the petty sessional division of Middle Holderness, Yorkshire East Riding; the animal attacked, a bull, was killed by order of the inspector. No healthy cattle were slaughtered from having been in contact with infected animals. The report for the week ending February 2nd states that on January 28 the disease appeared among the stock of a dairykeeper at Islington, in the Finsbury district of the metropolis, and during the week attacked 28 of the 46 cattle on the premises. The whole of the animals, whether diseased or healthy, have been killed. The number of animals attacked in Great Britain since the commencement is 253,860, and 52,641 cattle in the aggregate have been slaughtered healthy to prevent the spread of the disease.

ACADEMIE DE MEDECINE.—M. Legouest, the distinguished military Surgeon, was at the last meeting elected a member in the section of Operative Medicine. The other candidates were MM. Chassaignac, Demarquay, A. Guérin, Giraldés, and Verneuil.

THE Frankfort police has forbidden the sale of the fabric known as the green tarlatan, as it is dyed by colours composed in great part of arsenical preparations, and is consequently very injurious to health.

ROYAL COLLEGE OF SURGEONS, LONDON.—The following members of the college, having undergone the necessary examinations, were admitted licentiates in midwifery at a meeting of the Board on the 6th inst. :—

Messrs. Arthur Hensman, Northampton, diploma of membership dated Nov. 14, 1866; Joseph Arthur Williams, M.D., Victoria College, Toronto, Culloden, Canada West, Jan. 22, 1867; Eli James Barrick, M.D., Victoria College, Toronto, Jan. 22, 1867; John Cascaden, M.D., University, Toronto, Jan. 23, 1867; Titus Cummins Crooker, M.D., Victoria College, Toronto, Jan. 23, 1867; John Arnold, L.R.C.P.Lond., Demerara, Jan. 24, 1867; William James Hunt, L.R.C.P.Lond. and L.S.A., Hoxton, March 28, 1858; Rowland Hill Coombs, L.S.A., Bedford, July, 26, 1866; William Draper, Grantham, May 9, 1865; James D'Arcy Harvey, Plymouth, Nov. 15, 1865; and John Widmer Rolph, M.D., Victoria College, Toronto, not a member of the college. Professor Hilton, F.R.S., the senior vice-president of the college, will deliver the Hunterian oration on Thursday next in the theatre of the college.

DR. MASSINGHAM has been reinstated in his parochial appointment by the Bethnal-green.

The Faculty of Paris recently met in order to make a choice among the candidates for the chair of Surgical Pathology. M. Broca, M. Follin, and M. Verneuil were successively elected, and are to be presented for nomination to the Minister of Public Instruction.

A MEETING of the Council of the Metropolitan Poor-law Medical Officers' Association was held on Friday, February 8th, at 8 P.M., for the purpose of taking into consideration the report of a sub-committee on a uniformity of dietary in the Metropolitan union-houses, and generally to discuss the prospects of Poor-law Medical reform in the forthcoming session. As Mr. Hardy intends to bring in his bill on that day, the Council will arrange to meet *de die in diem*, so as to be prepared to take immediate action, should the interests of their body appear in any way to be imperilled. As a substantial measure of Poor-law Medical reform is anticipated, it is very desirable that all Metropolitan Poor-law Medical Officers should join the Association. Those that have not already done so may send in their names to F. Godrich, Esq., West Brompton, treasurer; T. O. Dudfield, Esq., 8, Upper Phillimore-terrace, Kensington, hon. sec.; or Dr. Joseph Rogers, 33, Dean-street, Soho, president.

ODONTOLOGICAL SOCIETY.—At the usual monthly meeting on February 4, the new President, G. Ibbetson, Esq., delivered his inaugural address, and a paper was read "On the Use of Carbolic Acid in the Treatment of Diseased Teeth," by James Bate, Esq., of Brighton. At the previous meeting of the Society a hearty vote of thanks was unanimously passed to the retiring President, Mr. W. A. N. Cattlin, the proposer of which observed that though Mr. Cattlin now chiefly practised at Brighton, he had never once allowed the distance from town to prevent his taking the chair at the Society's meetings throughout his year of office.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—At a meeting of the above Society, held on Wednesday, the 30th January last, George Burrows, M.D., was elected President, in the room of Martin Wane, Esq., resigned. Also, H. A. Pitman, M.D., was elected a Vice-President, instead of Dr. Burrows, and Dr. Fuller, a Director, vice Dr. Pitman.

PRESENTATION TO THE RESIDENT PHYSICIAN OF THE BRITISH GENERAL HOSPITAL.—On the 30th ult. the students of the British General Hospital held a meeting for the purpose of expressing their regret at the resignation of Dr. Walter Harris, late House-Physician, and at the same time presented him with a gold watch, in token of their esteem and regard.

The receipts from the working of the Atlantic Telegraph Company, up to the present time, have averaged £813 a day, including Sundays; since the reduction in the price of messages from £20 to £10, the average has risen to £874.

The report of the Inland Revenue states that coffee is largely adulterated with finings, which is simply burnt sugar or caramel, of about one-third the cost of duty paid coffee. The same report states that glucose is largely imported for the adulteration of confectionary and preserves.

A SURGEON'S assistant of the name of John Fisher committed suicide a few days since at Huddersfield. The coroner's jury returned a verdict of "Temporary insanity."

THE *Edinburgh Courant* intimates the death of Dr. Scoresby-Jackson, a nephew of the celebrated Arctic voyager, whose life he wrote. He was the author of several medical works, including one on "Climate," and another on "Materia Medica."

AN inquest has been held at the London Hospital on a child who was bitten by a dog on December 27th, and was discharged from that hospital, after three weeks' treatment, as well; but symptoms of hydrophobia having subsequently set in, it was sent back to the hospital, where it died. The jury, after hearing evidence, returned a verdict of "Death from bite of dog."

AMONG the samples of adulterated tobacco examined lately at the Inland Revenue Laboratory were several containing liquorice, others fermentable sugar, and some tannic acid, sulphate of iron, and logwood, whilst one sample of "roll" sent from Scotland actually consisted of oakum, covered with a thin wrapper of leaf tobacco, and was, from its outward appearance, indistinguishable from genuine tobacco. The principal of the laboratory gives the weight of tobacco yearly consumed per head of the population at one pound four and three-quarter ounces, which shows a continuous increase during the last twenty years.

THE CASE OF SHOOTING A SURGEON.—At Jersey, last week, Thomas Roberts, who was lying in gaol on a charge of attempted murder, committed suicide by hanging. The deceased about two years ago was an inmate of the General Hospital at St. Helier's, Jersey, and was attended for a bad leg by Mr. Charles Le Vesconte Godfrey, surgeon to the establishment. He was discharged and sent to England, where his leg becoming worse, he had to submit to amputation, much against his will. He returned to Jersey a short time ago, and made no secret of his animosity to Mr. Godfrey, whom he blamed for the loss of his leg, alleging that he had not had proper treatment from him. He had often been heard to utter threats against him. On the 6th December, as Mr. Godfrey was crossing the Parade, after paying his morning visit to the hospital, he was shot at by Roberts who was concealed behind a tree. The charge took effect in his left shoulder, and brought him to the ground. He lost a great quantity of blood, but recovered in the course of two or three weeks. Roberts expressed his sorrow that he had not killed him. Since his committal he had frequently declared to the turnkeys that he would never leave the island, and would rather hang himself. On Tuesday morning, when his cell door was opened at seven o'clock, he was found hanging quite dead. He had made use of his braces and a leathern strap, which he used for fastening his wooden leg to his stump. The braces were round his neck, and the strap fastened to a large spike rail in the wall. Deceased had formerly been a sailor, and was about 45 years old.

## Notices to Correspondents.

Dr. Dickie, of Alloa, has forwarded to us a correspondence between him and Dr. Brotherston anent the following dispute:—On Dr. Dickie's authority a statement appeared in a daily paper that cases of cholera had occurred in the town. Dr. Brotherston, the Medical Officer of Health, contradicts the statement in the following words:—

"Having made inquiry as to the reputed cases of cholera referred to, I find that they were not cases of Asiatic cholera at all, but that the parties died from other diseases."

Not having seen the cases or consulted Dr. Dickie, who had attended them, but basing his conclusion simply on the neighbours' hearsay. Furthermore, Dr. Brotherston makes the countercharge:

"That Dr. Dickie was one of those appointed by the local authority to make a house-to-house visitation, and, as such, was bound, according to the 7th clause of the Order issued by the Board of Supervision, to intimate to the Medical Officer the name and place of abode of every person affected with diarrhoea."

Dr. Dickie, in accepting the office of House Visitor, bound himself, in our opinion, to report the existence of diarrhoea to Dr. Brotherston, and was morally, if not legally, wrong in omitting to do so.

Dr. Brotherston was altogether unjustified in publicly contradicting the statement of a medical brother on no better authority than old woman's diagnosis, and, in our opinion, Dr. Dickie had just cause of complaint. From any evidence which Dr. Brotherston shows to the contrary, we think the cases were cholera.

The matter is hardly worth so much paper and ink, and might have been much more satisfactorily settled by a little professional cordiality.

## MEDICAL SERVICES AT CORONERS' INQUESTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Will you kindly oblige me with your opinion what course to adopt in the following case, or if I have any remedy to prevent the like being repeated.

On Sunday night, the 27th ult., about ten o'clock, two of the constabulary came to my house from Killeter, a distance of four miles, where my dispensary is situated, saying an infant child was found there that day in the river dead, and that the sercant requested my attendance in the morning between ten and eleven o'clock to meet the coroner, who lives near Strabane, a distance of eight miles. I accordingly drove there in the morning, viewed the body and was in waiting more than an hour before the coroner arrived; when I met him he informed me that he had called upon another Medical Officer on his way coming ("from another dispensary district whom he had often brought before into my dispensary district") and that he was coming after him, therefore he would not require my services, which I consider very unjust treatment, for it greatly interferes with the due administration of justice, as I was most likely to know of any cases of suspicion being in the district; and upon referring to the Medical Relief Register, I find several cases which I had strong reason to suspect being in a state of pregnancy, but the course the coroner adopted prevented me having a word to say in the matter.

Now, Sir, I would like to know if the coroner has power to employ any doctor he pleases from any other district in such cases. An answer will greatly oblige your obedient servant,

X.

[Favouritism of this sort is too common, and is altogether contrary to the spirit of the law. There is no legal obligation on the coroner to call in the medical officer of the dispensary district, but we think our correspondent is entitled to his fees on the ground that he was officially required to attend by the sercant on duty.—Ed. M. P. & C.]

## ASPHYXIA FROM CARBONIC ACID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Any explanation you may give as to the probable cause of death in the following case will much oblige:—I lately attended an inquest, and from the evidence given it appeared the conditions under which the deceased died were these:—One night during the late severe frost, when deceased was going to bed, he took with him in a "frying-pan" some red *turf-coals*, and laid the frying-pan on the floor near the bed. The room was a small one, ceiled over head, the door and window were very nearly air-tight, and there was no flue or chimney. There was no evidence as to the exact quantity of turf used, further than that it was stated there was but little ashes in the pan, but that the turf used gives comparatively but little ashes. Deceased was found dead in his bed next morning. There was some mucus about the mouth, but no appearance of a struggle. I attended the man about two months previously for an ordinary "cold," from which he quite recovered, and I am able to state that he was free from cardiac and other organic diseases. A week after death the body presented no appearance of apoplexy. The man was about 26 years of age, a labourer by occupation, and never regarded by himself or his neighbours as a delicate man. There was no smoke in the room when the door was opened in the morning. I thought carbonic oxide might be produced under the circumstances, but the coroner did not think it could. Any light you may throw on the matter will much oblige, yours truly,

A SUBSCRIBER.

[The case appears to have been one of carbonic acid poisoning—a common occurrence in the close cabins of ships. Did the persons who discovered the body in the morning suffer from asphyxia symptoms, or was there time for the effluvia to escape before their entry?—Ed.]

THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I beg a tiny space, just to thank "Speculum" and your other correspondent for their kind replies to my note, and also to inform them that my late distracting symptoms now prove not to have sprung from any morbid condition of the internal ear, nor from accumulated cerumen, but from a small chronic abscess external to the tympanum, which, having at length suppurated, my conscience, sir, will no longer allow me to subscribe myself, yours truly,

MISER.

## MEDICAL VACANCIES.

Bristol General Hospital.—House-Surgeon and Assistant House-Surgeon.

Chapel-on-le-Frith Union.—Medical Officer and Public Vaccinator.

Cardigan Union.—Medical Officer.

Reading Medical Dispensary.—Resident Surgeon.

Stockport Infirmary.—House-Surgeon.

Wakefield Lunatic Asylum.—Junior Assistant Medical Officer.

## MEDICAL APPOINTMENTS.

EATON, F. B., L.R.C.P.Ed., has been appointed Medical Officer for the Nuneaton District of the Nuneaton Union, Warwickshire, vice O. F. Wyer, M.R.C.S.E., resigned.

GREEN, J., L.R.C.P.Ed., has been appointed Medical Officer for the Middle District of the Pattingham Union, Yorkshire, vice T. A. McManus, M.R.C.S.E., resigned.

GWYDIA, R. C., M.R.C.S.E., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &amp;c., for the Drumlish Dispensary District of the Longford Union, vice W. L. Watkins, L.R.C.P.Ed., resigned.

HAY, Dr. W. H., of Bridport, Dorset, has been appointed by the Lord Chancellor a Magistrate for the Borough of Bridport.

LITTLE, R., M.D., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &amp;c., for the Toome Dispensary District of the Ballymena Union, County Antrim, vice C. Atkinson, L.F.P.&amp;S.Glas., resigned.

ANDERSON, J. G., L.R.C.P.Edin., L.S.A., L.M., has been appointed Resident Obstetric Officer to St. Mary's Hospital, vice Thurgar, term of office expired.

MEADE, WARREN, L.K.Q.C.P.I., M.R.C.S.E., L.M. Rotundo Hospital, Dublin, has been appointed Medical Officer to the Clayne Dispensary, County Cork; also to the Constabulary and Coastguard Stations in the Di triet.

MURIEL, R., M.R.C.S.E., has been appointed a Surgeon in Ordinary to the Ely Dispensary, vice A. Davies, M.D., resigned.

O'CONNOR, W. J. A., L.R.C.P.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &amp;c., for the Spiddal Dispensary District of the Galway Union, vice R. J. Morgan, L.R.C.P.Ed., resigned.

SINCLAIR, Dr. G. M., has been appointed a Surgeon in Ordinary to the Ely Dispensary, vice A. Davies, M.D., resigned.

SOMER, J., M.R.C.S.E., has been appointed Medical Officer for the Broadcliff District of St. Thomas's Union, Devon, vice F. H. Collings, M.R.C.S.E., resigned.

STERLING, H. H. J., M.R.C.S.E., has been appointed Resident Medical Officer to the Metropolitan Free Hospital, Devonshire-square, vice C. Smith, M.D., resigned.

SWANSON, G. J., M.D., has been appointed one of the Ordinary Medical Staff of the Edinburgh Dental Dispensary, vice R. Nasmyth, F.R.C.S.E., resigned (but who still retains office as Consulting Surgeon-Dentist).

VERDON, J. J., L.K.Q.C.P.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &amp;c., for the Horth Dispensary District of the North Dublin Union, vice J. Rorke, L.K.Q.C.P.I., resigned.

WADHAM, Dr. W., has been appointed Examining Physician to the Queen's Foreign and Home-service Messengers.

WRIGHT, G., M.B., C.M. Aberd., has been appointed Medical Officer and Public Vaccinator for District No. 11 of the South Molton Union, Devonshire, vice G. Allarton, M.R.C.S.E., resigned.

WOODMAN, J., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Eastern District of the Exeter Incorporation of the Poor, vice A. J. Cumming, M.R.C.S.E., resigned.

## MEDICAL DIARY OF THE WEEK.

WEDNESDAY, FEB. 13.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. A Lecture, by Professor Huxley.

THURSDAY, FEB. 14.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Vibratory Motion, with Special Reference to Sound."

FRIDAY, FEB. 15.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. A Lecture, by Professor Huxley.

ROYAL INSTITUTION.—8 P.M. C. F. Varley, Esq., "On the Atlantic Telegraph."

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

## BIRTHS.

FERNIE.—On the 4th ult., at Upton-on-Severn, Worcestershire, the wife of James Fernie, M.R.C.S.E., of a daughter.

WOOD.—On the 28th ult., at Newton Abbott, the wife of Dr. J. Hurd Wood, of a daughter, still-born.

PEACOCK.—On the 28th ult., at Ford Cottage, Churchinford, Devon, the wife of A. L. Peacock, M.R.C.S., of a son.

SHEPHEARD.—On the 31st ult., at North Walsham, Norfolk, the wife of John Shephard, M.R.C.S., of a son.

OLIVE.—On the 31st ult., at Northampton, the wife of Eustace Henry Olive, M.R.C.S.E., of a son.

BROWN.—On the 2nd inst., at Earlswood, Nottinghamshire, the wife of E. A. Brown, M.D., of a son.

MOXEY.—On the 4th inst., at Edinburgh House, Turnham-green, the wife of D. A. Moxey, M.D., of a daughter.

DAVIS.—On the 4th inst., at Abbey-gardens, St. John's-wood, London, the wife of Assistant-Surgeon Wm. Farquar Davis, M.D., H.M.'s Madras Army, of a son.

## MARRIAGES.

MACKAY—PILCH.—On the 31st ult., at Walker, Northumberland, J. T. Mackay, M.R.C.S.E., to Joanna, daughter of Captain Pilch, of Lowestoft.

BEVVIS—HOLMES.—On the 5th inst., at Park-circus, Glasgow, Charles Bevvis, M.D., of London, to Jane, daughter of the late James Holmes, Esq., Manufacturer, Paisley.

## DEATHS.

O'REILLY.—On the 17th ult., at New York, Dr. Bernard O'Reilly, formerly of Dublin, aged 65.

FRENCH.—On the 23rd ult., Henry Joseph French, L.R.C.P.Ed., of the Wandsworth-road.

EARDLEY.—On the 25th ult., John Eardley, L.R.C.P.Ed., of Charles-street, Westbourne-terrace.

MASON.—On the 28th ult., at Horninglow-street, Burton-on-Trent, William Mason, Surgeon, aged 65.

WOODFIELD.—On the 29th ult., at Killorglin, County Kerry, A. H. Woodfield, M.D., aged 38.

RUSSELL.—On the 31st ult., at Toulouse, W. T. Russell, M.D., aged 80.

HEWSON.—On the 2nd inst., John Hewson, F.R.C.S.E., of Lincoln, aged 67.

JONES.—On February 1st, at Foxley, West Bewdley, after a lingering illness, over two years, Wm. Allen Jones, Esq., M.R.C.S.E. and L.S.A., in the 41st year of his age.

VESEY.—Died at Bombay, Richard Murray Vesey, Staff Assistant-Surgeon, H. M. Indian Army, youngest son of the late Rev. George Vesey, of Inniscarra, Cork, aged 28.

## CLINICAL LECTURE

ON CASES OF

INFLAMMATION, DEPENDING CHIEFLY ON  
NEURO-VASCULAR DISORDER.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

I HAVE selected from my records for our consideration to-day some cases, where well-marked inflammatory phenomena occurred in parts accessible to ocular inspection. These will serve to put before our minds, if we study them carefully, some of the most important features of the process; and that in a more striking manner than is possible when internal organs are affected.

*Case 1.*—J. T., æt. 35, a tall, strongly-made man, was admitted June 11th, 1859. He was a discharged soldier who had fought all through the Crimean war, and escaped unhurt by sword or disease, or the terrible privations of that bitter winter. After leaving the Crimea, his regiment went to Cephalonia, where ophthalmia was endemic, and he and many of his comrades got the disease; some became blind. Strong caustic, he reports, was freely used to the eyes, and always made his worse. For some time he was at Kilmainham Hospital, in Dublin, and was discharged from thence with a small pension. After that he had been in a London hospital two months, but was not benefited. When I saw him he had very marked corneitis, the corneae were opaque, their surface traversed by red vessels, there was some conjunctivitis, his sight was very defective, he could scarcely guide himself about. Since some hot thundery weather he had become worse. His general health was very good. He remained under my care till June 11th, 1860, exactly a year, when I had the pleasure of seeing him quite capable of earning his own maintenance as a groom. Three months later the state of the corneae is thus described in my notes:—"The right is quite clear, a small speck of opacity remains in the centre of the left." Since then I have seen him occasionally, and I believe the recovery continues permanent. The remedies employed were very various, and for a long while the struggle with the disease was doubtful and obstinate. The ground gained was lost over and over again, as change of weather to wet, or some other slight cause, deranged the vital actions which were beginning to resume their normal play. Had he not been inured to discipline, and had not my sympathy for a brave fellow who had fought hard and suffered much determined me to persevere, and to hope even against hope, his chance of regaining useful vision was indeed small. Quinine in gr. v.—x. doses *ter die*, quinine with iron, ammon. carb. potass. iodid., oleum terebinthinæ, arsenic, guaiacum, strychnia, oleum morrh., opium, nitric acid, and bark, tannin were employed internally; and externally I used collyria of lead, alum, borax, tannin, silver, hydrocyanic acid vapour, blisters to the forehead, and dry cupping to the temples and neck. Of all these I have no hesitation in stating that tannin was the most useful by far. It was given in large doses, gr. xx.—xxx. *ter die*. By November 8th, that is, in about four months, the relapses were much shortened; instead of lasting seven or eight days, they were over in two or three. After being omitted some two months and half, the tannin was resumed in February, and continued until the end of the treatment in May. Some stomach disturbance was occasioned at one time, but it does not seem to have continued. The history affords a tolerably good example of what may be accomplished by persevering treatment with an obedient confiding patient.

*Case 2.*—J. R., æt. 30, smith, admitted May 19th, 1864. Has been ill five or six years with an eruption on the face, consisting of an aggregation of imperfect pustules covered with thin scabs, seated on a surface pretty uniformly affected with deep red congestion. The hair-bearing parts of the integument, the chin, cheeks, upper lips, and the eyebrows were the seats of the disorder, the hair growing

on them was much thinned. The face felt very hot and itching; if he exerted himself, he stated, that his face became very red, "all a mass of blood." The least excitement caused flushing. Soap made the eruption worse, and so did constipation of the bowels. His pulse was very weak, he was languid and below par; he had abstained from beer for six months. During nine months he had been a patient at the Blackfriars' Hospital, but had not benefited. On microscopic examination I was unable to detect any parasitic growth around the roots of the hairs which were firmly implanted in their follicles. It was evident that the minute pustules were formed around the hairs, where they had fallen out there was much less eruption. He continued under my care till about the end of January, 1865, *i.e.*, rather more than eight months, and was then discharged almost perfectly recovered. The chief remedies employed were arsenic, quinine, and a combination of iron, strychnia, and sulphate of magnesia. The arsenic was given for about five months, and the dose was increased to ℥ xv. of Fowler's solution *ter die*; the chloride and simple solution were also used part of the time. It was certainly very beneficial, but hardly so much as the combination above-mentioned, which dissipated the persistent hyperæmia, and very nearly restored the skin to its natural state. Tannin was tried in five grain doses, but did not appear at all beneficial. Of local applications I may mention a strong solution of nitrate of silver, which he declared "killed the itching," lead lotion of considerable strength (one in ten) and hot water. The effect of the latter was very noteworthy. He remarked that the face was more cooled by applying hot water—as hot as he could bear it—to the part, than by cold. This statement is borne out by that made to me by a lady's attendant, who noticed that after the daily wet-sheet packing, the patient's skin was paler than it was at any other part of the day. The packing was employed for the relief of a psoriasis which had rendered almost the whole of the cutaneous surface as red as a boiled lobster. Trousseau (*Clinique Med.*, vol. ii., p. 645) has some observations to the same effect. He speaks of the great antiphlogistic power of caloric, and remarks, "*L'action du chaud est en définitive sédative, tandis que celle du froid est éminemment phlogistique.*" In another case of sycois, also of non-parasitic origin, where the skin of both lips had assumed a red, tuberculated aspect, arsenic alone, with citrine ointment, continued about two and a-half months, sufficed for a cure.

*Case 3.*—A. B., æt. 25, had recently, when I saw him, returned from a tropical country, where he had suffered from ague, and very specially from an eczematoid eruption of the face proving intractable to all treatment as long as he remained in that climate; considerable improvement had ensued since his arrival in a colder. His general health was good, and there was no other apparent cause for the malady than the injurious influences to which he had been exposed. When he sat still there was nothing very remarkable about his face—it was only rather too red; but when he walked about, or was in any way excited, took a little stimulus (even a glass of claret), or was exposed to heat, the colour became much deeper—in fact he flushed strongly. Sharp frosty weather was evidently beneficial, and of pharmacopœial remedies, tannin, with muriatic acid.

*Case 4.*—W. N., æt. 77, applied, Jan. 5th, 1867, at St. Mary's, on account of frost-bite which had occurred during the previous day of severe frost, while he was at work on the roads. To restore his benumbed hands when he came home he put them first into warm water, and afterwards held them to the fire. When seen, the thumb and index-finger of the left hand, the thumb and middle finger of the right, were much swollen at the tips, and the epidermis more or less raised by reddish serum effused beneath it. In all the fingers the vesication was well limited, but there was diffused redness some way up the fingers. The tips of all the other fingers were numb, and remained so for at least a fortnight after the occurrence of the frost-bite; they were not, however, visibly injured. Subsequently, the epidermis and the nails separated from the affected digits, leaving red, more or less granulating, surfaces. At the

tip of the left index there was a distinct black slough of the cutis, which was not detached until about three weeks had elapsed. The patient is a feeble old man, who has long suffered with stomach symptoms, too probably indicative of the presence of slowly-advancing cancer.

The above cases are, I hope, not without interest in themselves, as examples of particular affections; but I purpose making them serve as the text for some general remarks upon inflammation. Trite as the theme may be, it can never lose its interest for the thoughtful practitioner, who cannot but desire to gain some insight into the nature of a process, the manifold varieties of which so constantly present themselves to his observation. The parts concerned in inflammation are, or may be, the tissue of the locality, its vessels and nerves, and the blood. As to the first of these, we can hardly question that it exerts a control over the blood which traverses it; that the movement of the latter is in a measure determined by the nutritive actions of the tissue. If the latter are vigorous and active, the current of blood through the capillaries is rapid and free; if the reverse is the case, the blood-flow slackens and is sluggish. There can be, I presume, little doubt that the increase of temperature which is observed in a working muscle depends on the greater amount of blood which it receives. The waking and active brain, we know from direct observation, receives more blood than it does during the period of sleep. The same, we find from Bernard's researches, is the case with glands, although in this instance it may admit of doubt whether the hyperæmia or the increased action of the tissue takes the initiative. The arrest of blood in the pulmonary plexuses during apnoea seems to be distinctly traced to the cessation of the proper function of the lungs, to the interruption of the exchange between this fluid and the air in the vesicles which stands in the place of solid tissue. The moment that fresh air is readmitted to the lungs the blood reddens and begins to move on. The low erysipelatoid inflammation which so often appears in the limbs of the dropsical in their last days, where the blood seems utterly to stagnate in the cutaneous vessels, and remains in them even after death, can hardly be referred to anything else than a failure or derangement of the normal nutritive actions of the skin. Similarly, the congestive redness which appears on a part which is threatened with a bed-sore can surely be ascribed only to the injurious effect of the pressure on the vitality of the tissue. It is, indeed, quite the reverse of what we should have expected if we had regard only to the blood-vessels. The repeated careful examinations which I have made of the frog's web, when stasis was about to occur from the irritant effect of the vapour of ammonia, have most fully convinced me that the arrest of the red corpuscles depends not on any adhesion of them to the walls of the vessels, though this does subsequently occur; but on an interruption of some unseen conditions which previously rendered their transit through the capillaries perfectly facile. The stream is suddenly checked; the corpuscles, still floating free, oscillate to and fro, and seem to be withheld from passing on their way by some invisible force which soon overcomes the *vis a tergo*. The question occurs—whether a sudden contraction of the minute arteries produced by the irritant could give rise to this phenomenon? It is conceivable that this might be the case; but I must reject this explanation, because such a contraction would certainly not cease immediately, and the arteries, as stasis becomes established, are for the most part dilated and pouring in full currents of blood; because the commencing stasis may at first affect only a few capillaries, and the circulation be going on briskly in those adjoining; and because, after a very short time, the red corpuscles do most evidently adhere to the walls of the vessels, so that it is well-nigh certain that, even at this time, some alteration is taking place in the forces operating on these floating cells. Another phenomenon which seems very indicative of a disturbed action in the tissues, is the regurgitation of blood from the veins towards the capillaries which are the seat of stasis. This I had observed for myself before I read in Rokitsansky's second edition of vol. i. that it had been discovered by Weber. Lastly, I may refer

to the evident tendency of the inflamed tissues to lapse into decay as another evidence of their essential concernment in the inflammatory process. Mr. Liston, in his able paper, of which a summary is contained in the "Proceedings of the Royal Society," No. 27, p. 584, comes to the same conclusion as I do. He points out how, when the irritation has been insufficient to cause actual stagnation, successive fresh portions of blood passing through the irritated area experience precisely the same change, consisting in slow movement of numerous and adhesive corpuscles.

The state of tissue excitement above described is always most marked in the early period of inflammation; it has—if not kept up by some cause, external or internal—a tendency to decline more or less rapidly, as is well evidenced by certain cases of pneumonia which terminate favourably in no long time when left to themselves, as well as in various external inflammations, such as those produced by blisters. This tendency to decline seems to be materially promoted by moist warmth, local depletion, and certain internal remedies. While it exists, tonic and astringent remedies—which, by constricting the arteries and so lessening the hyperæmia, would otherwise be most beneficial—are very apt to be injurious, acting, in fact, as irritants to the over-excitable tissue.

The derangement of the tissues conditioning inflammation cannot, I think, be uniform and identical in kind in all cases. In some, the saturation of the part with exudation is the most striking feature; in others, its rapid decay by ulceration or sloughing; in others, again, the rapid exfoliation of more or less abnormal cell-growth. In the second of these conditions, the power of forming living corpuscles is altogether arrested; in the latter it is excessive and perverted. Sometimes the effused fluid remains a long while among the tissues unchanged; more often it coagulates or corpusculates rapidly. These differences appear to me, from consideration of Mr. Lister's admirable researches on the coagulation of the blood ("Proc. of Roy. Soc.," No. 56), to be probably dependent on different states of the tissues; the more the latter approximate to dead matter, the more speedily is the coagulation.

As to the *blood* itself, besides what I have already stated, it may be remarked that observation of what occurs when resolution of stasis is taking place goes to confirm the view that some abnormal attraction of the corpuscles for the tissue, and for each other constitutes its essence. One evidently sees that some attraction, which holds together the stagnant corpuscles, and binds them to the capillary wall, gradually yields. The *vis a tergo* begins to prevail, the obstructing mass, whose liquor sanguinis has drained away, gets loosened in its channel, moves to and fro, at first with feeble, afterwards with larger excursions, then breaks up gradually into its constituent corpuscles, and so passes away into the veins. At and about this time individual corpuscles are still seen adhering to each other, and to the walls of the vessel; but nothing can be seen of any physical medium by which they are so attached. Although I do not question that the red corpuscles and white in passing through the capillaries of an irritated area, become adhesive, or, in plain terms, sticky; yet I cannot consider this stickiness as the main cause of their adhesion together and to the wall of the vessels. Usually, no doubt, the corpuscles are applied with their surface against the wall; but I remember observing on one occasion a red corpuscle attached by one extremity to the wall of a vessel in which circulation was returning, while several of its fellows, one after another, swept slowly past, brushing against it as it waded in the current. No mere glutinous matter could have attached a corpuscle in this way. Again, I am perfectly certain that the slackening of the blood current which precedes stasis does not depend on any adhesion of the corpuscles. It is evidently not any physical barrier that prevents their passing on in the normal way. The retardation of blood noticed by Mr. Paget in the inflamed wing of the bat cannot, I think, be explained by adhesion of the corpuscles, but plainly indicates an abnormal attraction of them to the tissue. Adhesion would cause stoppage, not slow movement. Knowing as we do that the red cor-

puscles in blood removed from the body cohere together, and more rapidly in inflammatory than they do in healthy blood, it seems a legitimate conclusion that their natural tendency to aggregate is in some way prevented in the healthy living system, and that its occurrence during inflammation is the result of this vital (*i.e.*, peculiar to living organisms) force being deranged or suspended. The increase of fibrine which occurs in inflamed blood, is to my thinking much more to be regarded as a deterioration of the blood-crisis than the reverse. Moreover, we have also to remember the well-established fact, that this fibrine may be, and often is, of a very abnormal kind, its corpuscular greatly preponderating over its fibrous element, so that indeed it is not far removed from pus. The deep red colour of urine passed during the existence of inflammation of any extent contrasted with the very pale colour of that which is secreted when the process has come to an end makes it, I think, very probable that during the increase and acme of the malady the red cells perish more rapidly than usual. As these are the chief living constituents of the blood, we have here another indication of its vitality being impaired, as we have already concluded that of the solid tissues to be while they are affected with inflammation.

The vessels concerned in inflammation are the smaller arteries, capillaries, and veins. Relaxation of their contractile circular coat seems to be the only alteration which the arteries and veins undergo, or at least the most important. I have certainly seen the arteries in the affected part more or less contracted, but this has been chiefly, I think, after stasis has been fully established. In the commencement of the process, and in the area surrounding it, the general result of observation is that the arteries are dilated. This paralytic relaxation, however produced, is a main cause of the hyperæmia which prevails so markedly in and around the focus of inflammation. By it, of course, the intra-vascular pressure in the affected district must be materially increased. It must be reckoned as another evidence of the enfeeblement of the component elements of the inflamed part in regard to their normal endowments.

With respect to the capillaries, it must first be remarked that their structureless wall is naturally endowed with a retentive power of the contained blood, which varies, however, remarkably even the state of health in different localities, and varies still more in manifold morbid states. Thus the capillaries of the muscles, no doubt, allow a certain moderate amount of liquor sanguinis to transude through their wall; those of the kidney are peculiar in allowing a very large amount of watery liquid to escape; those of the air-cells of the lungs permit little more than gaseous fluids to transverse them; those of the adipose tissue give exit chiefly to oil, and so on. This peculiar filtering power, as we may term it, is very prone to be deranged by various causes. Increased intra-vascular pressure is one of the efficient and most commonly met with. Malaria, states of nervous depression, obscure influences, such as the influenzal miasm, certain cachexiæ, are also not uncommon. The effused fluid may vary from mere serosity with a minimum of organic matter to perfect liquor sanguinis, or the same mingled with corpuscles in varying amount.

Now, I think we may state, as a rule, to which, however, there may be many exceptions, that the above-mentioned alterations in the arteries and capillaries coincide, that when the muscular coat of the former is relaxed the homogeneous membrane of the latter becomes less retentive than normal. There is, I think, also a tendency in the tissue of a part to fail in its vitality at the same time that its vessels fail, but unless it has been previously inflamed, unless the "bramble" has been given to the steadiness of its nutrition, this derangement of the tissue is not apt to occur. The converse is much more frequent—that the vessels follow, are involved in, the quasi paralysis of the tissue. There are many familiar instances in which we may observe the prime importance of the vital condition of the tissue. If that be sound and vigorous, a large quantity of blood may traverse the part with no ill result. Its functional activity will be increased as long as the hyperæmia continues, and its nutritive power is unexhausted. If the latter, however,

fails the hyperæmia will soon become a source of injury. Herein probably is contained the reason why inflammation is so much more common on thin membranes, mucous or serous, than in solid masses, such as the liver, brain, or muscle. The latter have a higher degree of vitality, and do not so readily yield to the influence of disturbing causes.

I have as yet said nothing relative to the concernment of the nerves in the inflammatory process. In truth, I believe there is not much to be said, for the chief part which the nerves play consists in their regulating the contraction and dilatation of arteries. Their paralysis, of course, conditionates arterial dilatation, and very probably also increased permeability of the capillary wall. A common nasal catarrh affords sometimes a good opportunity of observing how the amount of exudation is dependent on the condition of the general nerve force, operating, of course, upon the blood-vessels. I have again and again found that fatigue and fasting increase the profluvium, while rest, food, and moderate stimulation check or arrest it. In fact the process is the same in this case as when the cutaneous glands are excited to secretion by active exertion. Whether the direct or reflex irritation of any nerve is capable of exciting inflammation in the part to which it is distributed, appears to me at present very uncertain. There can be no question that paralysis of vasomotor nerves will conditionate inflammation in predisposed systems. Dupuy mentions an eruption over the whole cutaneous surface as being produced in horses from whom both superior cervical ganglia had been removed. A case occurred in this hospital about two years ago, in which, during a patient's third attack of hemiplegia, about fourteen days after its invasion a well-marked pemphigoid eruption appeared on the hand and foot of the paralysed limbs, about six ounces of clear blister-like serum came from the foot alone. There was at this time a good deal of delirium. Both it and the eruption ceased at the end of the third week, but the paralysis continued. The shock to the nervous system produced by surgical operations or burns sometimes gives rise to a red rash closely resembling that of scarlatina. Dr. Anstie, in his Lettsomian Lectures, has given some excellent examples of well-marked erysipelas being induced during the paroxysms of neuralgia in a district of skin supplied by the tortured nerve. Now, pain, let me remind you, is, in my view, a mode of paralysis of sensory nerves, as I have tried to show in my Lumleian lectures, and it is therefore not surprising to me to find a sensory associated with a vasomotor paralysis. Considering the close resemblance of herpes facialis and herpes zoster, as far as the appearance of the groups of vesicles, the great differences in the amount of attendant neuralgia in different instances of the latter, and the fact that both disorders come to an end spontaneously, I am much inclined to believe that both are produced in the same way—*viz.*, by paralysis of certain vasomotor nerves; but that, in the zona, this condition of the vasal is associated with a more or less severe neuralgia of the sensory. The pain and the eruption correspond pretty accurately in their localization, just as they do in cases of facial neuralgia attended with erysipelas or erythema.

To return now to our cases. In the first it seems to me that the fault lay more in the vessels and nerves than in the tissue. It is true that the latter became very opaque from interstitial exudation again and again, but it showed a notable power of recovering its normal condition as soon as the hyperæmia was effectually controlled. To do this required the long sustained influence of a powerful astringent, which operated no doubt on the minute arteries and capillaries, restoring them to that normal state of contractile and retentive power, in which they were so evidently deficient. It is remarkable how extremely sensitive feeble nerves and vessels often are to minute atmospheric changes. A bunion will ache and be painful for many hours whenever a change of weather is approaching, although there is yet no appearance of change. In the second and third cases we have a very similar state of vessels to that which prevailed in the first, but there is this difference between the two latter, that in the patient with sycosis the tissue of the skin was more deeply in-

volved than in the patient with eczema. This was evidenced not only by the process in the former having for its chief seat the deep-seated hair follicles, but by the effect of heat, which mitigated the disorder in him as much as it aggravated it in the other. Tannin was rather injurious to the sycois, but has benefited the eczema. The diffuse flushing which occurred in this man's face on exposure to the heat of a fire, on exertion, or on taking a very mild stimulant showed how weak and low was the contractility of the arterioles of his face which gave way on the least increase of intra-vascular pressure, or application of relaxing influence. Suppose the vessels of the bronchi, of the large intestine, or those of the pulmonary plexuses in a like condition, we can readily perceive how grave and difficult of management such disorder would be. This is probably one considerable reason why attacks of bronchitis in the aged, especially during this inclement season, are so intractable and fatal. The nerves and vessels of the membrane having lost much of their natural endowment are readily paralyzed by any depressing influence brought to bear upon them, as that of cold acting inhibitorily through the cutaneous nerves. The action of arsenic which availed so much in the cure of one and sufficed for that of a second case (v. B. M. J. 1862, December 6th) of sycois may, I believe, be formulated as follows:—it is a specific stimulus to the vessels, and nerves and tissue of various parts, inprimis to those of the skin. For its successful operation it is essential that the tissue of the part should not be irritable, not too near that which exists in acute inflammation, for if it be so, the stimulus acts injuriously, and increases existing disorder. If, on the other hand, a passive state of the tissue can be ensured, the drug may act most beneficially on the tissues and vessels, restoring the latter to a due degree of contraction, and so abolishing hyperæmia and its results. The great utility of arsenic in neuralgia, chorea, and intermittent fever justifies the assumption that it acts primarily on and through the vasomotor nerves in effecting a cure of inflammatory conditions. The combination of a saline aperient with iron and a nerve, which completed the cure of the case of sycois, is a very valuable one in many instances of chronic inflammation, where the tissue is intolerant of an unmodified stimulus. It depletes the engorged vessels and tones them at the same time.

In the case of frost-bite, it seems to me evident that the prime cause of the inflammation was the depression of the vitality of the skin by the cold. It is possible that by very gradual and cautious stimulation, the half-dead parts might have been restored without suffering injury, but his practice of applying heat lavishly, by relaxing the blood-vessels, gave rise to far more blood-flow than their weak vitality could endure. What a traumatic lesion does in one instance, the gouty poison in another, arsenic in a third, heat locally applied in a fourth, &c., the cold effected here; that is, it reduced the condition of the affected part nearer to that of dead matter, in consequence of which, when the blood began again to circulate through the part, the normal relations between it and the tissue were quite deranged. The means which you should employ to restore the damaged vitality of an inflamed tissue vary very much according to the particular circumstances, thus bearing out fully what I have already stated, that the deranged condition of the tissue in inflammation is by no means uniform and constant. I must reserve what I have to say on this head to another occasion, and will now only ask you to carry away with you these notions:—(1.) That the causative condition of an inflammation may consist in impairment of the vital properties, either of the nerves and vessels on the one hand, or of the tissue on the other. (2.) That in most instances both factors are simultaneously at fault, though probably not in equal degrees. (3.) That the tissue is apt to be most criminal in the earlier period of inflammation, the nerves and vessels in a later, and in more prolonged cases. (4.) That in cases where the disorder is chiefly neural and vascular, very marked success may be achieved by the persevering employment of tonic and astringent remedies.

CLINICAL LECTURES  
DELIVERED IN  
STEEVENS' HOSPITAL,  
TOGETHER WITH  
OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,  
PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,  
PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REMARKS ON CHLOROSIS AND HÆMORRHAGE.

(Continued from page 138.)

CHLOROTIC patients are liable to various incidental affections of the lungs. Acute bronchitis and acute pneumonia are not of very common occurrence; nor is bronchial hæmorrhage, or pulmonary apoplexy. These are more likely to occur in cases of anæmia produced by antecedent hæmorrhage or wasting disease, than in true chlorosis. I have, however, occasionally seen chlorosis complicated with circumscribed chronic pneumonia, and frequently with chronic bronchitis, terminating ultimately and remotely in tubercular phthisis. In this affection, therefore, a prolonged and intractable bronchitis is a formidable symptom. Nevertheless, when I compare the number of chlorotic cases ending in phthisis, with the number of hæmorrhagic cases ending in the same disease—judging from my own sphere of observation—I find the latter greatly to exceed the former. I may further add, that, in the prophylactic treatment of phthisis, considerable modification is requisite; inasmuch as that which is best calculated to prevent the chlorotic, is not, in all its details, equally suitable to what may be termed the hæmophysical phthisis. I have seen a few cases of chlorosis complicated, some with periodic, others with irregular spasmodic asthma.

Chlorotic patients are also subject to a very great variety of incidental disturbances and perversions of the digestive function, which, in some cases, throw serious obstacles in the way of treatment, and render it more tedious and difficult. Of these, one of the most frequent is the distension of the stomach, which arises after meals, no matter how simple and easy of digestion the food may be. In many instances we meet with most distressing gastric and intestinal flatulence; not such as results from mere indigestion, but a copious and continual secretion of gas, similar to that which we so frequently find to arise in hysteric patients. This symptom is sometimes accompanied with a constant noise and motion of the intestines; a rumbling so loud as to be audible to those around, and exceedingly distressing to the patient. The gas, pent up by irregular contractions of the intestines, is the cause of severe and sharp pains, not only in the abdomen, but in remote situations. It is often the sole cause of intense pains in various parts of the chest, shoulders, sides, and also along the limbs; pains which are at once removed by any medicine which has the effect of expelling or even displacing the confined air. In such cases a portion of the intestine may be observed to swell, and thus form a large, circumscribed, tympanitic tumour. These symptoms are greatly relieved by warm, cordial cathartics; by stimulating frictions and rubefacient applications, such as mustard or turpentine, over the abdomen; and by small, frequently-repeated doses of the rectified spirit of turpentine internally. A drop or two of creasote, in a pill to be taken thrice daily, is often exceedingly useful when given in conjunction with the compound galbanum pill. Galbanum itself, in full doses, is in some cases a most effective remedy. I have also seen marked advantage to arise from newly-burned and finely pulverised carbon; the charcoal derived from box-wood is, I think, the best; and the less the powdered charcoal is exposed to the air the more efficient it is. The following powder has proved itself, in many instances, a remedy of value: Of freshly-burned charcoal reduced to fine powder, a scruple; calcined magnesia,

ten grains; powdered nutmeg, five grains. Mix. To be blended with a little milk first; then a sufficiency of water or milk added to suspend the powder, so that it may be easily taken. It may be repeated two or three times daily. Should the bowels be disposed to relaxation, powdered crabs' claws or precipitated chalk may be substituted for the magnesia. I have known chlorotic patients who had been greatly harassed by these incessant gaseous secretions—after every variety of treatment and the most careful regulation of diet had failed to procure more than temporary alleviation—ultimately and completely cured by travelling and repeatedly changing the air. Amongst the occasional symptoms which complicate chlorosis, we meet with instances of an extraordinary perversion of appetite. Those so affected are very unmanageable patients. As this symptom, however, belongs more properly to hysteria than to chlorosis, we shall not dwell further on it here.

It has been already remarked that chlorosis is usually characterized by obstinate constipation, and that it predisposes to collections in the colon and rectum of indurated feces, enormous masses of which are sometimes thus accumulated. As the bowels will sometimes act whilst these still remain lodged in the cells of the colon, the accumulation may easily be overlooked; we must, therefore, be careful that this evil, which interferes with and prevents all successful treatment, may not elude our vigilance. I saw lately a well-marked case of chlorosis in which a large, hard mass of fecal matter occupied and distended the pouch of the rectum; it was so firmly lodged as to require mechanical means to effect its removal.

Amongst the less frequent, but by no means uncommon complications of chlorosis, serous effusions demand especial notice. The tendency of this affection, as contra-distinguished from hæmorrhage, is to give rise to exudations of serum, whilst exudations of blood are comparatively rare. These effusions, which are common both to chlorosis and anæmia, may be poured out either into the serous cavities, or into the cells of the subcutaneous cellular tissue. Whenever the blood, from any cause, is reduced to an extreme degree of attenuation, we have much reason to apprehend such a catastrophe.

The following case illustrates chlorotic anasarca:—

A married lady, aged 19, had been for several months labouring under gradually-increasing chlorosis. Previously to her marriage she had looked pale and delicate, and had lost much of her accustomed health, strength, and spirits. Marriage, it had been expected, would have had a salutary effect; and for a short time, whilst travelling, her health appeared to improve. She again, however, became languid, depressed, and pallid, and at length universally anasarca. In this state I first saw her. She was confined to bed; her debility so great that it was with difficulty she could be moved; and her whole person was enormously distended. Her face was œdematous, but less so than every other part of her body; a copious serous effusion had taken place universally into the cells of the subcutaneous cellular tissue. Her pulse was incalculably rapid, and so feeble that it was with difficulty it could be felt at the wrist. The heart's impulses were languid in the extreme, but unaccompanied by any abnormal sound. The respiration was permanently and greatly accelerated. The alvine excretions were liquid and of light yellow colour; she was so weak and helpless that she could not be placed on the bed-pan. The urine was light-coloured, not copious, of low specific gravity, but without a trace of albumen. A variety of treatment, both tonic and diuretic, had been in vain employed, and all hope of recovery abandoned; and yet there was no evidence of organic disease; the sole change which had taken place was in the blood itself. From the appearance of the skin, and from the slightness of the pressure necessary to displace the fluid, it was evident that the effusion was of the thinnest nature. Under these circumstances I thought this an unusually favourable case for acupuncture. The operation was immediately performed; a great number of punctures were made, from which thin serum flowed copiously, and much care was taken to keep the patient dry and warm. Common salt was dissolved in water, to which the muri-

ated tincture of iron was added; and of this as much was given, at regular intervals, as the stomach could easily endure, together with farinaceous nutriment and wine. On the next day the patient's condition was in every respect an improved one; the anasarca was diminished, the pulse more distinct and less frequent, the respiration less hurried, and the urine much increased in quantity. On the second day many additional punctures were made, and on the third day they were again repeated. After this day the greatly increased flow of urine, and the marked diminution of every urgent symptom, rendered it unnecessary to reiterate the operation. She gradually—I may truly say rapidly—recovered; her restoration was perfect; she became vigorous and even florid; she has borne several children; and many years have since elapsed, leaving her in the enjoyment of uninterrupted health.

The next case I shall record is one of great interest,—a case of extreme anasarca, the result of anæmia, and without organic lesion, occurring in an hospital-patient. He was about thirty years of age, had never lived intemperately, and was superior to the generality of hospital-patients in manner and education. His life had been spent in an office, at the desk, the nature of his occupations permitting him to take very little exercise. By long continued and frequently profuse bleeding from the hæmorrhoidal vessels, he was reduced to a state of complete anæmia, and, owing to extreme debility, had been compelled to give up his situation as a clerk. When admitted into hospital he was universally anasarca. The first signs of œdema manifested themselves in the lower extremities and face; his respiration was hurried; his pulse feeble and rapid; no murmur accompanied the cardiac movements, nor was there any auricular evidence of deposition in the pulmonary cells. The urine was scanty, low in density, and not albuminous. He remained for several days in hospital, and the symptoms not being in the least degree submissive to treatment, it was determined to give exit to the fluid by acupuncture. Numerous punctures were made, during several successive days, in different parts of the body; the thin serum flowed freely; the anasarca subsided; the secretions became abundant; and the treatment ultimately issued in a complete restoration to health. His diet was gradually rendered more and more nutritious; he was allowed wine and malt liquor; and after the operations, his medicines were iron and ammonia. I cannot avoid recording an emphatic expression used by this man. After having been twice acupuncture, and when the serum was flowing profusely, I asked him how he felt? His reply was: "Sir, I feel greatly relieved: when I was a boy, I wept from my eyes; now that I am a man, I weep from my whole body."

These cases illustrate the circumstances under which the operation of acupuncture may be most advantageously employed; indeed the only circumstances which give to it a permanent value. It may often be practised usefully as a palliative: rarely, however, is it a curative measure. In dropsy from organic disease it removes the tension, and enables the blood to circulate more freely, so that the medicines may act, and the effused fluid be absorbed; but the organic disease remains, and the dropsy returns. In the foregoing cases there was no organic lesion, either cardiac, pulmonary, hepatic, splenic, or renal. The tension being removed, and the medicines enabled to produce their full effect, the serous effusion was absorbed, the constitution invigorated, the quality of the blood improved, and the cure rendered perfect. Far otherwise is it in those vastly more numerous cases of dropsy resulting from morbid change and deposition in organs essential to life; in many of these, acupuncture is an useful adjuvant in the treatment, but it cannot remove the cause of the effusion.

Trifling as this operation is, I have seen it followed by consequences the most disastrous—erysipelas and gangrene. In advanced cases of dropsy, when the blood is much altered—all but disorganized—it is dangerous to puncture the skin. I have also seen cases in which, from the perpetual oozing of cold serum, the broken-down state of the health and of the blood, each puncture has been followed

by a large and foul ulcer. In other instances of hopeless dropsy, even though the patient escape these grave consequences of acupuncture, the limbs have been kept so constantly wet and cold as greatly to distress the patient and aggravate his sufferings. It requires, then, observation and judgment to distinguish the cases in which this remedy may be safely and successfully employed. It may be here remarked that the more limpid and less dense the effusion, the more favourable is the case for acupuncture. I have observed many cases of anasarca resulting from organic renal disease, wherein it required strong pressure to produce a pit or dimple; nay, more, the limbs have been so rigid as to render the joints immovable, such has been the density and solidity of the matter which occupied the subcutaneous cellular tissue. I have preserved the records of several interesting facts to illustrate the various degrees of density of the fluid effused in the different forms of anasarca swelling; which on some future suitable occasion I hope to bring before the profession.

I saw, some years ago, in consultation with Sir Philip Crampton, a very remarkable case of anæmic dropsy; the patient was about thirty-five years of age; he had been reduced by long-continued and profuse hæmorrhoidal bleeding to a state of extreme anæmia. The prominent symptoms were death-like pallor, excessive debility, languor, constant dyspnœa, occasional orthopnœa, bellows-murmur of the heart and arteries, universal anasarca, and peritonæal effusion. Sir P. Crampton, by an operation, put an end to the sanguineous exudation, whereupon a rally took place; and then tonics, diuretics, moderate stimuli, and nutritious diet, completed the cure.

Formerly, cases of chlorosis characterized by unusual disturbance of the cardiac action were treated as genuine organic diseases of the heart. Repeatedly, in the early part of my professional life, I have witnessed the pernicious effects of this mistake. I have seen patients who needed iron, solid nutritious food, and the open air, treated by weeks or months of recumbency, digitalis, repeated bleedings, and abstemious diet. Fatal in its results must such treatment be. At the present day mistakes of this nature are of exceedingly rare occurrence; cases, however, do occur, the diagnosis of which is involved in some obscurity. Œdema of the lower extremities, co-existing with orthopnœa, startings in a fright from sleep, violent palpitations and systolic murmurs, are symptoms calculated to render the diagnosis obscure and difficult.

The following case of chlorotic anasarca, which fell under my notice many years ago, made a deep and lasting impression on my mind. It was that of a young lady, who, without any palpable or discoverable cause, had gradually fallen into a state of extreme chlorosis, her debility being such that she was confined to bed. She was unable to remain long in the recumbent position; she lay with her chest and shoulders elevated—the only position in which, with comparative ease, she could breathe; she was seized frequently with paroxysms of dyspnœa and palpitation; the lower extremities were much swollen, and the œdema extended to the hips. When I saw her, she was pallid and prostrated in the extreme; her pulse feeble, rapid, and unequal; a bellows-sound accompanied each systole of the heart, and a similar murmur was heard along the line of the large arterial tubes. I could not discover any venous hum or sound. In the lower extremities a very slight degree of pressure produced a deep pitting. The occasion of my visit was to determine whether, being provided with a bed in a travelling carriage, she might be removed from this city to the residence of her parents in the south of England. Her case was looked upon and had been treated as one of hopeless organic disease of the heart. A carriage, with a well-constructed bed, was provided; she was taken out a few times for a short drive, which she bore well. Her journey homewards was then determined upon. Each day's travelling was followed by a manifest abatement of the most urgent symptoms: the good derived from travelling was so obvious that it was persevered in. She continued to travel for a long time, and re-

turned quite a renovated person. I saw her years afterwards full of health and spirits.

I was not then as well aware as I now am, of the extent to which an extremely attenuated state of the blood is capable of disturbing the cardiac and pulmonary functions, so as even to simulate heart disease. Nor was I fully acquainted with that form of dropsy or anasarca, which may appropriately be termed anæmic anasarca; a variety of dropsy usually looked upon as resulting merely from debility, but in reality dependent upon the remarkable attenuation in the quality of the blood which takes place in the advanced stage of chlorosis and anæmia. It is distinct, and easily distinguishable from the anasarca which accompanies Bright's disease of the kidney; it holds a separate place, and may be placed under the head of chlorotic and anæmic dropsy. A dropsical effusion frequently takes place in the last stage of purpura hæmorrhagica; this too depends upon an alteration in the constituent elements of the blood,—an alteration, however, in some respects, of a nature different from that which characterizes chlorosis.

(To be continued.)

## Hospital Reports.

### THE LONDON HOSPITAL.

#### CLINICAL REMARKS ON A CASE OF ELEPHANTIASIS.

Under the care of Mr. HUTCHINSON.

THERE are two diseases to which the term elephantiasis has been applied, quite distinct from one another; elephantiasis græcorum, true leprosy, which is very rare in England, and of constitutional origin; and an elephantiasis attended with local hypertrophy, but not usually with constitutional disease.

Mr. Hutchinson considered this latter affection to be due to impediment to the circulation, causing œdema, which would still further interfere with the circulation by its own weight. The tissues being flooded with nutrient material (blood) begin to grow enormously; first of all the structures of the skin, papillæ, &c., then the deeper structures, even the bone. He showed two interesting specimens, from the museum, of the bones of the leg crusted all over with new growths, which he had no doubt were from a case of elephantiasis. In one, about the middle of the tibia, there was a circumscribed oval patch, with a well marked margin of new bone all round it, most probably the seat of an old ulcer.

He pointed out that elephantiasis was common in those parts liable to œdema, as the scrotum, penis, &c., and legs.

He believed that whenever the papillæ had once become very much enlarged, it was impossible to really cure the disease, though much might be done, if the leg, for instance, were affected, by rest and careful bandaging.

The case which led to these remarks was that of a young woman, with great hypertrophy of the clitoris and labia minora. She was also the subject of constitutional syphilis, and he should think that though the elephantiasis was not itself a specific disease, yet the œdema produced by the gonorrhœal inflammation, &c., had led ultimately to the present state of things. He hoped by rest to reduce the swelling a little, and when the syphilitic affection was cured, he intended to remove the growth, as he did not think it would ever get well without it. He alluded to several cases of elephantiasis of the leg recently under care at the London and Skin Hospitals. He had never himself dissected a limb affected with elephantiasis, but the results of such have been recorded by Continental writers (Wedl).

He insisted that the distinction between solid and permanent œdema of a dependent part and elephantiasis was merely one of degree, and that the two conditions were usually met with together. The greater the degree in

which the papillæ were involved, the more applicable did the term elephantiasis become. He alluded also to the influence of local inflammations in starting the processes which result in elephantoid hypertrophy. Thus chronic ulcers on the leg, venereal ulcers, and discharges from the genitals are the most common causes of the disease as it is met with in English practice.

#### SPONTANEOUS LATERAL DISLOCATION OF THE PATELLA.

About a month ago, a healthy girl, 8 years of age, was brought to Mr. Hutchinson, at the hospital, who could displace her right patella at will. It was unusually loose, and whenever she bent her knee it slipped outwards. The left was quite normal. It was said that she had only been able to do this for the last six months.

In some of these cases there is very decided inward bend of the knee, by which the displacement of the patella is to be explained. In the present case, however, there is little or no tendency to knock-knees, and it is to be further noted that the first displacement occurred spontaneously, and not in connection with any violence.

#### INTRA-UTERINE UNION OF HARE-LIP.

Mr. Hutchinson had also lately an interesting case of hare-lip, in which partial union had taken place before birth. The infant was about six weeks old, and the fissure had been on the left side only. At the upper part there was an evident scar left by cicatrization, but the lower part was still open. The palate was not involved.

Mr. Hutchinson completed the half-finished cure in the usual way.

In clinical remarks on this case, Mr. Hutchinson stated that the union by cicatrix did every now and then occur during intra-uterine life. He had seen three or four cases in which infants were born with a scar extending through the whole length of the upper lip, exactly in the position left by that of a successful operation. In fact, nothing but the most conclusive testimony of the little patient's friends, and the absence of the scars of the needles, had in these instances removed his incredulity as to the condition being congenital.

#### NOTE AS TO IMPROVEMENT OF SPEECH FOUR YEARS AFTER OPERATION FOR CLEFT PALATE.

An opportunity occurred for noting the ultimate result, as regards the voice, of a successful operation for cleft palate. The patient was a young woman, on whom Mr. Hutchinson had operated four years ago for a cleft of the whole of the soft and the posterior part of the hard palate. The result had been most satisfactory. All the parts had well united, except a small notch in the end of the uvula, and she considered herself as remarkably improved in distinctness of utterance. She could really talk very well indeed. Many would not have noticed any imperfection. Before the operation her speech was very bad.

#### SYMMETRICAL CELLULAR NODES ON THE KNEES.

There is now in Sophia Ward a healthy-looking, fresh-complexioned woman, æt. 44, with a tertiary syphilitic ulcer, the size and shape of a shilling, in front of each knee. Gummy tumours in this situation are common enough on one side, but we rarely see this condition symmetrical. Mr. Hutchinson frequently draws attention to the fact that tertiary syphilitic manifestations rarely show themselves at the same time in corresponding parts of the body or limbs, whilst, on the contrary, the secondary phenomena are almost invariably symmetrical.

In the case mentioned above, the ulcers are rapidly healing under the influence of ten-grain doses of iodide of potassium.

#### ST. GEORGE'S HOSPITAL.

#### STONE IN THE BLADDER: LITHOTOMY.

Under the care of Mr. POLLOCK.

On Thursday last we witnessed the operation of lithotomy performed by Mr. Pollock, on a young man who had been

in St. George's Hospital about a month. There was nothing remarkable in the case, and chloroform having been given the operation was performed with considerable skill, two large calculi being extracted. A very brief delay was caused by one calculus being lodged in a kind of pouch behind the prostate. Each calculus had a sort of shell as a coating which broke into many fragments on being seized by the forceps.

In the course of some remarks addressed to the pupils who had witnessed the operation, Mr. Pollock stated that the young man came into the hospital without the usual symptoms of stone. But as his urine was alkaline attention was directed to the subject, and the calculus detected. He exhibited the two large calculi he had just extracted, and which he considered were probably at first composed of lithic acid; afterwards these would set up irritation, and the phosphatic deposits would take place on the lithic nucleus. A number of large fragments of the shell were subsequently removed.

#### DISEASE OF THE FEMUR.

Under the care of Mr. H. LEE.

On the same day Mr. Lee operated on a young woman for a very chronic disease of the thigh bone. Chloroform having been given, Mr. Lee cut down upon the trochanter, and proceeded to extract the diseased bone by means of the gouge and the trephine. He informed the class that the disease was of several years' duration. After being in the hospital a little to recruit her strength, he thought it well to operate. At first he was not prepared to find so extensive a mass of the cancellous structure so completely diseased. Mr. Lee exhibited the portions he had removed, showing how, on squeezing, purulent matter was exuded, as if it were a sponge saturated with pus. It was clear that the patient, already greatly reduced, could not recover without aid, but now that, as he thought, the whole of the diseased tissue was removed, some hope might be entertained of a favourable issue.

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, FEBRUARY 1, 1867.

Dr. BUTCHER, President of the College, in the Chair.

#### SPECIMENS OF PATHOLOGICAL AND ANOMALOUS ANATOMY.

By ALEXANDER MACALISTER.

THE specimens which I have for exhibition this evening are of some interest, and were met with by me in the College of Surgeons' dissecting-room. The first is an instance of enlargement of the left lateral lobe of the thyroid gland, taken from the body of an elderly female of whom I had no history. The right lobe and isthmus were of normal size, but the left was enormously enlarged, extending downwards into the thorax, displacing the trachea to the right, and the great vessels to the left, flattening the sympathetic and recurrent laryngeal nerves, and pressing on the œsophagus. When cut into, it was found to consist—1st, of a lamina of unaltered substance; 2ndly, of a hard somewhat cartilaginous structure, too far decomposed for microscopical investigation, but presenting all the physical features of a cancerous texture. The same subject had a scirrhus enlargement of the left ovary, and a single point of Farre's tubercle just at the transverse fissure of the liver. Scirrhus in the thyroid body is a disease of rare occurrence, but has been described by Von Franke in the *Deutsche Klinik*, vol. 39, and also by Cæsar Hawkins and Holmes Coote. The other specimens are interesting, as being rare forms of muscle arrangement; the first being an example of a third tendinous band for the biceps, springing from the outer lip of the bicipital groove, in common with the tendon of the great pectoral, while the other is an example of a not uncommon arrangement of the palmaris longus from the same arm, showing a round condyloid tendon of origin, a central belly, over four inches in length, and a flat tendon of insertion. Another specimen is that of a very common, though seldom noticed,

arrangement of the coraco-brachialis muscle—namely, its insertion into a tendinous sling overlapping the tendon of the latissimus dorsi. Henle, in his valuable "*Muskel Lehre*," figures this as the normal arrangement, which, indeed, seems to me to be the case.

I might, in conclusion, mention an interesting case of arterial irregularity, in which the femoral artery was accompanied by two venæ comites, and gave off the external circumflex, internal circumflex, and profunda separately; then, becoming popliteal, divided into peroneal and posterior tibial, the former branch sending off the anterior tibial. This rare case is interesting, as showing the homotypes of the arteries to the upper and lower extremities.

The PRESIDENT observed that this tumour of the thyroid body was most interesting, as enlargements of it were constantly met with, and it became a difficult matter to diagnose as to whether the surgeon should meddle with them or not. The case which Dr. Macalister had brought before them fully illustrated this. The tumour was of unusual size, pressing aside the main vessels and producing a good deal of embarrassment, yet upon the decision of the surgeon must rest entirely the relief of the patient from such a tumour as that. In cases of goitre there were many reasons why they should not meddle with them; but tumours, such as that exhibited by Dr. Macalister, were constantly removed by the practical surgeon. The instances of unusual attachments of the muscles, which had been brought under their notice, are also most interesting, bringing them back to those types of life in which these attachments of muscles are seen.

#### ADVANTAGES OF BLANDIN'S KNIFE FOR DIVIDING THE PREPUCE IN INFLAMMATORY PHYMOSIS.

MR. PORTER said he would not occupy the time of the Society more than a few minutes in bringing before the members a knife for operating in cases of inflammatory phymosis, which he had found both convenient and efficient. The simple mode of slitting up the prepuce had attracted notice from an early date, and instruments had been made specially for the operation, yet he had found none to answer so well as the one he was now about to bring under their notice, both as regards the ease and rapidity with which it could be used. Mr. Porter then read the following:—

The simple, yet important operation of slitting up the prepuce in cases of inflammatory, or acquired phymosis, has attracted notice from a very early date, and in the present day the practical surgeon is not unfrequently called upon to perform it. To evidence the importance in which the proper execution of this operation has always been held, I may mention that special knives have been suggested, and used by Guillemeau, Petit, Latta, and Charles Bell. It is almost a matter of surprise that the performance of this procedure should ever have aroused the ingenuity of those men to produce instruments peculiarly for it. Yet the judicious and rapid execution of even the most trifling surgical operation is frequently of paramount importance to the patient, and at the same time facilitates the surgeon in relieving the sufferer. When, from the presence of ulcers, or incarcerated discharge beneath, the prepuce becomes acutely inflamed, and enormously tumified; its orifice contracts so tightly, that any attempt to glide it back over the glans is found to be impracticable, and renders it difficult and painful to insinuate even a director through it, on which to guide a bistoury for slitting it up. It should be the object of every one to simplify as much as possible operations, and with this view the surgeons I have quoted advocated their several instruments for cutting the prepuce in this inflamed condition. Bell's mode may be objected to on the ground that two instruments are required when one might be made to answer the purpose. In fact, his mode of operating differed little from the ordinary manner of treating it in the present day. He used a sharp-pointed bistoury, on which a deeply-grooved director was made to slide, thus converting it into a sort of sheathed knife, as soon as the bistoury was in its proper situation it was pushed through, the director being firmly held. This sheath must have rendered the knife broader, more difficult and painful to introduce when the orifice was very much contracted; besides, it required the use of both hands to manage the instrument. Petit's plan also required two separate applications, the director and knife. Some Surgeons use button-pointed scissors to slit up the prepuce in those cases, but against this plan may be urged that it is slower, and does not make so clean a cut as the knife. Again, it has been proposed to fix a little rounded piece of wax on the extremity of an ordinary sharp-pointed bistoury, and insert the instrument thus

guarded. It is found, however, that the point often pierces the wax too soon, and renders it impossible to pass the knife thus denuded sufficiently far back to its proper position up to the corona glandis. It may be fairly inquired what can be more simple than the usual mode of operating by introducing a director, either by the side of the frœnum, as advocated by Cloquet, and guiding a sharp-pointed bistoury along this to divide the prepuce; or the still more common plan of passing the director above the glans back to the corona glandis, and upon it introducing a sharp-pointed bistoury, and then forcing its point through the integument, and quickly cutting forward with one stroke. I would reply, by stating what I have often seen with others, and experienced in my own practice, that the introduction of the director, particularly when the glans is ulcerated, gives a great deal of pain, even more than the rapid cut with the knife which follows. And in addition to this objection, the surgeon will find in cases where the orifice is much contracted, that the heel or broad part of the bistoury begins to cut the tightened orifice before the point reaches its proper destination; these are no mean objections in an operation so trifling as to be hardly worth while putting the patient under chloroform. And, furthermore, the two instruments require both hands of the operator to be employed with them, whereas one might, with more advantage, hold the penis in order to steady it. The knife I have latterly employed, and which I found so efficient, that I venture to recommend it to my professional brethren, is one invented by "Blandin" for section of the sphincter ani muscle. The blade is fitted to the sheath, so that it may be introduced completely masked. The sheath is movable, not the blades, which has the advantage of permitting the knife to be introduced to the proper position before unmasking its edge. When sheathed it is not larger than a common director, it is as easily introduced as a probe from its shape, and when passed to the corona glandis with the forefinger of the right hand placed on the bottom, the sheath can be drawn back into the handle, and the blade thus exposed may, in a moment, be pushed through the integuments, and the inflamed prepuce slit forward with the greatest rapidity. The knife can be managed altogether with one hand, whilst the other is left free to hold the penis in a proper position for the operation.

DR. FLEMING wished to ask Mr. Porter whether his remarks had reference to acute inflammatory, or to congenital phymosis.

MR. PORTER said it was to inflammatory phymosis he altogether referred.

DR. FLEMING would ask whether in the majority of the cases of acute inflammatory phymosis, the mere section of the prepuce is sufficient to effect a cure. Whether there be ulcerations or matter confined from the contraction of the orifice, he thought if they reflected one moment they would see that it would require more than a mere section of the prepuce to answer the purpose. He approved of this simple section of the prepuce in those cases where there was contraction of the orifice and inflammation to a certain extent; but in many of the acute cases in hospital practice, the mere section of the prepuce would not answer, and it was often necessary to remove a considerable portion of the prepuce itself.

MR. MACNAMARA:—The point before the Society is simply a knife to divide the prepuce, and not the general treatment of phymosis.

The PRESIDENT ruled that the subject of phymosis generally could not be entered upon. The matter before the Society is merely a simple mode of dividing the prepuce in inflammatory phymosis. The knife exhibited by Mr. Porter they all had in their instrument cases. It is generally used for opening sinuses in the neck, and in situations where there was a difficulty and danger in introducing an ordinary instrument. The knife is a beautiful one, exceedingly applicable to the cases in which Mr. Porter had used it, and particularly to all those cases where there was terror created by the use of large instruments.

MR. PORTER said that the President had exactly explained the object which he had in bringing this instrument before the Society. He claimed nothing new for himself in the matter.

#### SALIVARY CALCULUS.

DR. LEECH thought it might be interesting to exhibit to the Society a salivary calculus which he had recently extracted. Ranula was a common disease, but calculi were not common even of this size. In Wharton's duct they were rare, and in Steno's duct still rarer. The person from whom this specimen was taken was a farmer aged about forty, and of healthy ap-

pearance. He came to him (Dr. Leech) on the 12th of December last, stating that for three weeks previously he had had sore throat, and for the last few days had found it difficult to swallow any food. He also said that for some time he had had a swelling under his tongue, but that it gave him very little trouble till the last fortnight. On looking into the man's mouth he perceived a large tumour under the tongue pressing that organ upwards and backwards, and presenting all the appearance of a common ranula, but on examination it was found to be much more dense and inelastic than those tumours usually are, and on pressure there was a very slight oozing from the orifice of the Wharton duct at the right side of a white matter resembling pus. He (Dr. Leech) at once proceeded to lay open the tumour with a sharp bistoury, when the point of the instrument struck against a hard stony body, which immediately revealed the nature of the case, and after some little difficulty, a calculus about the size of an almond was removed, the top sharp portion being separated from the larger end. The patient got immediate relief, and next day reported himself well. This man had no tartar on his teeth. Dr. Mapother had made an analysis of the calculus, and found it was composed of 60 parts of carbonate of lime, 30 of phosphate of lime, and 8 of organic matter. The analysis made from time to time of these calculi differed very much as to the ingredients of which they were composed.

Mr. E. HAMILTON asked whether there was found any trace of sulpho-cyanide of potassium.

Dr. LEECH said Dr. Mapother informed him that there was no trace of it whatever.

Dr. MAPOTHER observed that the quantity of the calculus which he examined was very small, not more than two grains and three-tenths, so that his analysis might not be as satisfactory as might be desired. He could find no trace of sulpho-cyanide of potassium. Claude Bernard had never found that salt in saliva except under diseased conditions, when the breath was very foul, and a great deal of tartar on the teeth. Bernard thought it was the result of decomposition, but at all events he had never found it in any healthy young person with clean teeth. Six years ago a patient sent him a calculus larger than that extracted by Dr. Leech, and there was not the slightest trace of carbonate of lime in it, whereas, in this instance, more than one half of the quantity he examined was carbonate of lime, the remaining ingredients being phosphate of lime, and organic matter. The organic matter seemed to be dried mucus, and had the burnt feather smell when heated.

Mr. E. HAMILTON. As to the statement that sulpho-cyanide of potassium is not a constituent of ordinary saliva, he was prepared to contradict it from his personal experience. He had obtained it in perfectly healthy saliva.

The PRESIDENT observed that as there was some doubt as to the analysis, he thought it would be well if a larger portion of the calculus were examined, and the result reported to the Society. He suggested, therefore, if Dr. Leech would devote the calculus to this purpose, that Mr. Hamilton, Dr. Mapother, and Professor Macnamara be requested to undertake the analysis and report to the Society at its next meeting.

The gentlemen named undertook to make the analysis.

#### THE CIRCUMSTANCES WHICH CONDUCE TO THE SPREAD OF CHOLERA.

Professor MAPOTHER read a paper on the circumstances which conduce to the spread of cholera. The disease was imported into Dublin from Liverpool on the 26th of July last, and spread to three other houses on City-quay. Several other cases were traceable to communication with this case, directly or indirectly, but, as in other maladies, the contagion cannot always be traced. An abstract of meteorological observations was also given, from which no positive result could be deduced. Dr. Mapother endeavoured to show that three conditions should concur for the origin and spread of cholera; 1st, the germ; 2nd, a porous undrained state of soil; and 3rd, a peculiar kind of receptivity. In discussing the former, he controverts the doctrines of the Commissioners of Health of 1849. He dwelt particularly on the influence exercised on the spread of cholera by a bad and deficient water supply, and cited two instances mentioned by Dr. Snow to show, in one case, the decrease of cholera following improved water supply, and in the other, its increase when the quality of that necessity was deteriorated. The cases of cholera in Exeter in 1832 exceeded 1000. The water supply was by carriers from the river, into which all the sewage flowed. Before the next visitation, which devastated the country, the water was taken from two miles above the town, and in 1849 but 44 cases

occurred, and in 1854 hardly one. Hull, in 1832, was supplied with pure pipe water, but so scantily that the poor had to resort to other means to obtain it; 300 people, mainly the poorest, died of cholera in that year. In 1844 a supply was abundantly procured for all classes from the river, and accordingly, in 1849, 1834, persons from all ranks fell victims to this ignorance or negligence of the poisonous effects of contaminated water. In Swords, a little town of some 1400 people, 65 cases of cholera occurred in seven weeks. The water supply was from an unprotected well, subject to great defilement. In the village of Crumlin, out of 165 inhabitants 46 were seized with cholera and choleraic diarrhoea. A single and most superficial pump was the sole water supply, and its produce was often stinking and muddy. Kingstown suffered far more than Dublin in proportion to population, and at least one of the promoting circumstances was a wretched supply of water, exclusively supplied by wells. After two cases of cholera, one of which was fatal, had occurred in the house of a friend of his (Dr. Mapother), which was situated in one of the best parts of the town, he poured a quantity of carbolic acid into the sewer, and found that the water of the adjoining well tasted of that substance for many weeks afterwards. It was almost certain that the sewage had in the same way percolated before the appearance of the cholera. The rate in Kingstown was over twice that of Dublin, and higher than that of East London. Although the disease began two months later than in Dublin, the weeks of greatest mortality were the same—the 20th and 27th of October. Dr. Mapother thought there could not be a reasonable doubt that cholera was a malady produced by the entrance of a poison into the human body, the digestive canal being the site upon which it specially fixes. Whether such poison was gaseous or suspended in the atmosphere; whether it was an organized body, vegetable or animal, they knew not; but if the latter supposition be true, we might believe that it could be carried through the air without injury to its communicable power, and that if dried, like vegetable germs, it might regain its power by moistening on our mucous surface. If caught by the surface of the mouth or nostrils it would be swallowed, and thus reach the digestive canal, if that be the only habitat where it can develop. The aerial diffusion of the specific germ will account for the wide-spreading of a diarrhoeal tendency at cholera periods, and the dilution which such a mode of conveyance necessarily implies, accounts for its impotence or mildness in the vast majority of cases. The diffusion of the same germ in drinking water secures the impregnation of the system with a much larger dose of the poison than can ordinarily be inhaled by the lungs from the surrounding air, and in this way can be explained, by the light of Pettenkofer's views, the enormous fatality which has followed upon such contamination. The second concurrent circumstance is terrestrial. As far as Dr. Mapother had been able to ascertain, the same streets in this city, which had been lately attacked, were those which suffered in the two previous epidemics. The local miasm-producing condition, according to Pettenkofer, is the existence of a porous soil impregnated with human excreta, not necessarily choleraic, and over-lying springs at no very considerable depth. The most favourable time for the specific excitant germ to be received into such a locality is, when the springs have just sunk unusually low after having been unusually high, or when hot dry weather succeeds rainy weather; the rain would raise the sub-soil water, and when it sunk during the drought, the high temperature would promote the decomposition of the organic matter it left behind.

The two best cases in illustration of the indispensable presence of a porous, moist, and impure subsoil which Pettenkofer gives are as follows:—The transport ship *Carnatic* was lying off Madras waiting to embark troops, whilst an epidemic of cholera was raging there. In the mean time, the sailors were as usual allowed their liberty days ashore, on a soil predisposed and amidst a population succumbing to this disease. The troops for which the transport was waiting, on coming down to Madras from an uninfected inland country, were, by a well-informed commanding-officer, marched right through the town, without halting in it, and the ship put to sea. After seven days the cholera broke out among the sailors, but, though they were nursed by the soldiers, they communicated the disease to none of them, the contagious factor of cholera being present in abundance, but the peculiar soil for the production of the miasmatic condition being of course absent. In like manner, the sailors in Admiral Dundas's flag-ship *Britannia* fell ill, sixteen days after leaving Varna, with cholera of a most virulent type, and though so great a mortality took place on board

that they were compelled to supply themselves with additional hands, from an uninfected ship which they fell in with at sea, and to transfer some of their own sick to it in return, not the least communication of the disease to the fresh ship's crew took place.

Suspecting that there was a close relation between the prevalence of cholera and the presence of water-courses in a neighbourhood, Dr. Mapother marked on a modern map of Dublin the streams which are traced on Speed's map (A.D., 1610), and Rocque's map (1756), afterwards dotted in the spots where all the deaths by the late epidemic ensued. The result surprised him, for there is the closest correspondence between these circumstances. Three-fourths of the deaths occurred within 200 or 300 feet of these water-courses, and the remainder are scattered singly over the city. There are few cities more completely encircled and intersected by water-courses than Dublin. The Royal and Grand Canals are ditches of stagnant water, and form a circle very nearly complete round it, the only break being between the docks at James's-street and Broad-stone, a distance of about a mile—along high ground, too, which would throw water back.

The Liffey runs through nearly the centre of the city, and if its low level makes it improbable that it induces an understratum of water in its neighbourhood, it contributes to the production of cholera by the stagnation and rotting of the sewage cast into it. The returning tide carries back any sewage which may have flowed seaward, and salt-water encourages its putrescence. The minor streams are—the Poddle, which, entering the city at Dolphin's-barn, divides into many branches, and flows through the entire of the south-western quarter of the city, and communicated with the ditch around the old walls of the city. Another stream, probably the Tongue, which Provost Baldwin directed from the Dodder at Clonskeagh, flows through Camden-street, Upper Mercer-street, and Clarendon-street, to open by a smaller branch into the Liffey at Aston's-quay; and a larger one runs across Grafton-street (where, by its bursting, a woman was drowned in a kitchen) towards Townsend-street and George's-quay. Another water-course is traced on old maps at Baggot-street, Hamilton-row, through the College-park (where it is remembered as the Haha), and Shaw-street, to join the Liffey at City-quay. The Camac, arising near Rathcoole, courses through Kilmainham, Bow-lane, and Watling-street to the Liffey. The sewage of the Richmond Barracks flows into the river, and the nuisance thus created is at present the subject of litigation. It formerly bounded Usher's-island on the south. On the north-side, the Bradogue entering at Grange-gorman, passes through Bolton-street, Boot-lane, and Arran-street, to open at Ormond-quay, and a stream is traced in Rocque's map passing from Phibsborough, across Eccles-street and Dorset-street, to join the river just named. On the same map, there are pools figured at Gregg's-lane, Mabbot-street, Earl-street, Ellis's-quay, Island-street, and City-quay, just where cholera lately raged. Dr. Mapother gave a list of cholera fields along these water-courses, each having a radius of 440 feet; and said that there were, in fact, very few cases of cholera in Dublin, except in houses built over forgotten streams and pools imperfectly drained. The streets which stood highest above water-mark were notably free from cholera, or what to his mind more fully demonstrated their salubrity—it was introduced, and did not spread, but this rather depended on the concurrent absence of water-courses. A sudden fall in the city, by the gravitation of sewage and sub-soil water, promoted the disease notably; for instance, Cook-street runs along the river Liffey, only 300 feet from it, and 24 above high water-mark, while southwards the ground rises so fast that the parallel street, High-street, which is about 200 feet distant, is 36 feet higher. The district near Ballybough-bridge, or as it is classically called, "Mud Island," and that around St. Laurence O'Toole's Church, is reclaimed land, where drainage is necessarily imperfect, and in which the houses are so wretchedly constructed, that the mere earth, or at most, boards laid directly on it, forms the floor. To the same character of soil the prevalence of the disease in the neighbourhood of Montgomery-street may be assigned. Hanover-street, East, around which many deaths occurred, was also built on reclaimed land, and the drainage of that district had been much obstructed since the Grand Canal Docks were constructed. Without the utmost care being taken in draining land reclaimed from the sea, and in building houses thereon, it can never be salubrious. With regard to susceptibility or receptivity, it is incident to all that the humbler classes suffer most from a cholera outbreak. Scarcely a person in comfortable circumstances died within the City of Dublin during the

last visitation of the disease. Pettenkofer considered that a watery condition of the blood, with a superabundance of imperfect fibrin, was favourable for the taking of cholera, and this condition which existed normally in the child, and in the aged, could be produced artificially in ourselves or in the lower animals by overwork, and by the partial deprivation of the animal and other nitrogenized articles of diet, which are so essential to vigour and firmness, and to resistance to all catching diseases. Experience has shown that cholera is most fatal to the very young, to the very old, and to the very poor, to whom animal food is such a rare luxury. The striking immunity of the Whitechapel Jews in the last, as well as all former epidemics, was due to the timely distribution of animal food, and to their excellent hygienic observances, which has made longevity of this race one-third greater than that of most European people. In India, the outbreaks so often follow a failure of the rice-crop, that some have attributed the malady to some fungus from that grain. The want of free air to oxygenate the red-cells of the blood, and the neglect of cleanliness of the skin, may be other predisposing causes amongst the poor. Intemperance by depressing health, and especially by checking the removal of carbonic acid and other excrete matter, was also referred to by Dr. Mapother as a predisposing cause of all catching diseases. It was recorded that thirty cases of cholera occurred on New Year's morning, 1832, in Gates-head, no case having been previously seen. Nearly all the victims had been intemperate the night before. It was probable, however, that some antecedent conditions of the alimentary canal existed. Dr. Mapother concluded by describing the preventive and curative measures which, he thought, should be adopted, and advocated the establishment of refuges for the families of those attacked, while their houses were being disinfected.

The PRESIDENT said that Dr. Mapother's paper was a most interesting and valuable one, containing as it did facts in connection with the cholera epidemic down to the latest moment. The Society owed a debt of gratitude to Dr. Mapother for bringing before them that interesting communication, which exhibited so much labour and research.

The Society adjourned to February 15th.

#### HARVEIAN SOCIETY OF LONDON.

JANUARY 18TH, 1867.

Dr. POLLOCK, President of the Society, in the Chair.

Dr. C. DRYSDALE related the case of a man, aged 36, a cab-driver, who had suffered from cyanosis and heart disease as long as he remembered. The patient's nose and cheeks were purple; his finger-ends were livid and clubbed; a systolic, blowing murmur was heard, loudest at the apex, but also loud at the base of the heart. There was much crepitant rale and high-pitched percussion, not below the left clavicle. The patient was always very cold, even in summer, but was able to work.

In another case now under his care at the Metropolitan Free Hospital, in a man aged 60, the rate of the pulse was only 36 in a minute. This man, too, suffered from great chilliness. He had had rheumatic fever some years ago. No heart disease was perceived in this case. Dr. Drysdale had recently had another patient whose pulse was only 32 in a minute.

The PRESIDENT had never seen clubbing of the fingers in any case where phthisis was absent, except in one or two rare cases of empyema. Cyanosis, contrary to Rokitsansky's assertion, was, as in the case above mentioned, by no means unfrequently followed by phthisis.

Dr. CHAPMAN remarked that in cases of slow pulse the temperature of the body was usually very low. Dr. Fergusson, shortly before his decease, had suffered from a very slow pulse.

Mr. WEEDEN COOKE mentioned the case of a lady from America who had consulted him for cancer of the breast, and whose pulse was only 26. Her fingers were often frozen. Another lady was obliged to use warm water in the morning to make her fingers bend, and in winter time or cold weather they remained frozen all day long.

Mr. ADAMS mentioned the case of a surgeon whose pulse was habitually 28. He had suffered from fever in the Crimea, and was always cold—sometimes very cold; but, on the whole, had good health. He could not use stimulants, as they proved hurtful to him. There was no disease of the heart in this case.

Mr. HOLTHOUSE thought that slow pulse was to be attributed to some affection of the organic nerve centres. In syphilitic disease of the brain and in injuries to the brain the pulse was often very slow.

A paper was read by W. ADAMS, Esq., F.R.C.S.,

ON THE TREATMENT OF HIP-JOINT DISEASE.

The author divided hip-joint disease, in its ordinary form, as it usually occurs in children, from four to fourteen years of age, into three stages—the *first stage* extending from the commencement of the symptoms to the formation of abscess; the *second stage* extending from the formation of abscess to the bursting or opening of the same; the *third stage* the complete destruction of the joint, after the bursting or opening of the abscess, more or less extensive disease of the bone, dislocation, &c.

After adverting to the symptoms and progress of the disease in its different stages, the author referred to the different views entertained of the pathology of the disease, with respect to its commencement as a primary affection in the cancellous tissue of the bone, the view entertained by the late Sir B. Brodie, or in the articular cartilage, and alluded to the difficulty of determining this point, from the absence of post-mortem examinations at this period, as such examinations could only be made when death occurred from some other cause during the early progress of hip-joint disease. One such opportunity had occurred to Mr. Adams, and the details were, he said, recorded in the first volume of his "Translation of Chelius' Surgery." The appearances in this case corresponded with those observed by the late Mr. Acton Key in a similar case, in which death occurred in the first stage of hip-joint disease, and proved that in these cases the disease commenced, as Mr. Acton Key had remarked, in the round ligament, which, in both instances, was proved to be the seat of chronic inflammatory changes, extending to the adjacent synovial membranes, and in Mr. Adams' case, to the commencement of ulceration of cartilage in the neighbourhood of the ligaments. Essentially, however, the articular cartilages and bones were healthy in both cases. From the clinical history of these cases, supported by the post-mortem examinations referred to, Mr. Adams believed that hip-joint disease usually commenced in the round ligaments as the result of an accident in which this ligament was violently strained or partly torn, and that from this spot, as a centre, the disease extended to the rest of the synovial membrane, the articular cartilage, and, at a later period, to the bone. This Mr. Adams believed to be the ordinary course of events, although in some cases other structures might be primarily involved.

As to treatment, Mr. Adams' observations referred principally to the first stage of the disease, during which it is alone possible to cure the affection.

Regarding this disease as a slow form of inflammation, essentially chronic in its character, and associated with a condition of constitutional debility, and generally a strumous diathesis, Mr. Adams was opposed to the application of leeches and all severe counter-irritation, such as blisters, moxas, issues, the actual cautery, &c., as tending to exhaust the powers of the patient rather than to benefit the disease. Essentially he relied upon rest to the joint, with warmth and moisture constantly applied. Mr. Adams also opposed anti-phlogistic treatment internally, and especially the use of calomel, or what is called the alterative treatment, as tending to lower the constitutional powers of the patient, and relied upon the exhibition of tonics, with cod liver oil, hypophosphites of lime and iron. With regard to the means of securing rest to the joint, a paramount necessity, Mr. Adams was opposed to long-continued recumbency by confining the patient to bed or to his couch. Complete recumbency he thought necessary only for a short time during the more acute symptoms, with severe pain, when he used either the straight splint, or the more modern plan of extension by weights attached to the leg. Of the latter treatment he gave several examples, and alluded to an able paper by Mr. Marsh in the Bartholomew's Hospital Reports. Generally Mr. Adams employed a leather or gutta-percha splint, of larger size than ordinarily used, and moulded to the side of the body and limb, whilst the latter was held in the straight position, so as to overcome all muscular contraction, chloroform being administered in some instances. The first effect of such a splint, when properly made, was usually to relieve pain and enable the patient to move about with the assistance of crutches, thus materially benefiting the health and doing good to the disease. In the second and third stages Mr. Adams relied chiefly on the same principles of treatment, and preferred to open abscesses rather than allow them to attain a large size.

Dr. ANDERSON did not agree that abscesses of this kind should be opened early. He believed that the disease commenced in the capsule of the joint. In a few cases in adults he thought that leeches, counter-irritation, and tincture of

iodine proved very serviceable. He thought that in all probability the bone did not go so deeply into the cavity as in health. The splint recommended by Mr. Adams was of great service. Children feel much comfort from it. He would feel inclined to use more active treatment at first than that recommended by Mr. Adams.

Mr. OWEN thought that the local application of the splint was not quite necessary at first. Mr. Adams' first stage, too, was a very long one. Occasionally the disease occurred in strong persons, and the inflammation was sometimes very acute.

Mr. HOLTHOUSE said that the diagnosis of hip-joint disease was usually very clear. It could only be confounded with psoas abscess. Acute cases were rather exceptional. As to treatment he must protest against the administration of two or three glasses of port wine, and he thought stimulants were rarely indicated, though they *sometimes* were, and in such cases the pulse fell on giving them. Local treatment was of no use. Blisters were injurious. Hot linseed-meal poultices were the only application likely to prove useful. Splints should be put on as soon as possible, although they never had the effect of drawing the head of the bone out of the socket, which was impossible, since it was held therein firmly by atmospheric pressure. The shortening was usually more apparent than real, as might be ascertained by measuring. Dislocation was rare. Special apparatus like those described by the author were sometimes very useful. It was not advisable, he thought, to open the abscesses in all cases.

Dr. DRYSDALE thought the treatment for all strumous diseases consisted in the attainment of good food and open air exercise, as far as possible, for the patient. He could not believe that so much wine could do good in cases of hip-joint disease in children, and he was certain that calomel and counter-irritation and leeches were extremely injurious in all diseases of true scrofulous. Mr. Hilton's plan of physiological rest for the part affected seemed to him to be the wisest plan of treatment, accompanied by good nourishment and fresh air, &c.

Mr. WEEDEN COOKE said that counter-irritation should rather be termed irritation in the treatment of hip-joint disease. He questioned whether any case recovered without some shortening of the limb. In a great number of cases of recovery the patients limped afterwards. It was very gratifying to him to hear that Mr. Adams so strenuously advocated the anæsthetic means of treatment for this disease, and opposed the middle-some treatment by means of calomel and opium, leeches, &c., which were formerly so much recommended. The lectures of Mr. Hilton on physiological rest, and the ideas therein expressed, were, in his opinion, the most important of all the late accessions to the scientific practice of the art of surgery.

Dr. ANDERSON could not sit still without protesting against the idea of the non-utility of counter-irritation, and of calomel and some cases of hip-joint disease. Calomel and opium, which was given for two or three days, he had found of great use in case of the disease occurring in adults.

The PRESIDENT said it was a remarkable fact that so great a change seemed to have come over the ideas of practitioners on the subject of the administration of calomel. Was the profession ready to come to the conclusion that calomel and opium were of no use in acute inflammation? Without going so far as this he would observe, that as hip-joint disease almost always occurred in persons whose vitality was low, or who were of a strumous constitution, he thought it should be treated on the same principles by which other diseases of the tuberculous kind were treated—namely, by supporting as far as possible the constitution by means of all the most invigorating and nourishing means in our power, and he entirely agreed with Mr. Adams that all violent counter-irritation or local means should be laid aside.

CURRENT LITERATURE.

A TRANSLATION of Liebig's *Food for Infants*, by the Baroness Lersner-Ebensburgh, has been published by Mr. Walton, of Gower-street. It furnishes full information as to Liebig's substitute for Breast Milk, and the original is rendered into very good English.

The translator, induced by the difficulty of inducing the poor to carry out the directions with sufficient care, has arranged for a company to supply the food in a liquid, milk form, fresh every day, in any part of London and the suburbs, at the low price of sixpence per quart. The effort is one which

must depend for support on the medical profession. This will not be wanting, since only good could result from the general use of better food for infants than they now usually obtain.

Dr. Alexander Robertson has published a valuable contribution to the *Pathology of Aphasia*. His pamphlet consists of a paper, read at the annual meeting of the Medico-Psychological Association at Edinburgh, and afterwards printed in the *Journal of Mental Science*. It is an able clinical review of the present state of the subject, founded on three cases that came under the author's care in his official capacity as Physician to the Glasgow Hospital. We have much pleasure in extracting Dr. Robertson's conclusions on the subject, as follows:—

"There is a lesion usually in the left hemisphere of the brain, of efferent fibres passing between the convolutions and the great co-ordinating centres, probably at some point of a line extending from the external frontal convolution to the corpus striatum, so that voluntary motor impulses for the articulation of language cannot be transmitted. The *essential* morbid change is, therefore, *motor*, and not *mental*. However, there is in most cases an accompanying degeneration of the powers of the mind, which varies in degree in different persons, but in the majority distinctly involves the general faculty of memory. The condition of the intellect does not differ from that which is associated with non-aphasic hemiplegia; but it would seem that the emotional powers are less frequently disturbed. It follows that there is no necessity for supposing the existence of an organ for language, as a defect in transmission along with general weakening of the mental faculties is competent to account for the various phenomena hitherto observed in the sufferers from aphasia.

"At present there is no sufficient explanation of the almost constant occurrence of the lesion in the left side of the brain. Theories have been advanced which either involve the belief in a departure from the general plan of nature in the quality of our "organs of relation," or suppose, what seems inconsistent with the wisdom of Divine arrangement, that organs have been created which never discharge the special functions with which they were endowed. It is suggested that it would be well, in the first instance, to establish beyond doubt that the absence of aphasia in morbid states of the right hemisphere is not to be accounted for by the escape of parts usually implicated on the left side, owing to some slight anatomical difference, such as is known to exist between other bilateral organs. Failing this hypothesis, let us search anew for some more satisfactory solution of the difficulty than has yet been proposed."

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 20, 1867.

### THE POOR-LAW BOARD AND THE METROPOLITAN POOR.

MR. HARDY, the President of the Poor-law Board, has lost no time in announcing his intention of bringing in a measure for the relief of some of those flagrant abuses which have long been known to exist in connection with the treatment of the sick poor of the metropolis. We say that these abuses have long been known to exist, but it is only at a comparatively recent period that they have attracted the notice of the several newspapers, and have thus been brought

before the public. The system of local government, excellent as it is in theory, has been carried to such lengths in the management of the sick poor, that no one dared to expose any misconduct, however flagrant, on the part of the authorities; and the Poor-law Board, which alone had the right to inquire into and control the proceedings of the Guardians, was content to perform its duties with its eyes shut, and its so-called inspectors degenerated into a mere routine. If any Medical Officer dared to advocate the cause of the sick poor who were placed under his charge, he was snubbed by his superiors or dismissed from his post, and his place was soon supplied by persons of less scrupulous character, or endowed with more worldly prudence. As there was, practically speaking, no appeal from the decision of the Guardians, it became with the Medical Officers a mere matter of common precaution to let things in general take their course, inasmuch as any unseemly zeal on their part would only expose them to insult, while the wretched salaries doled out by the Guardians deterred many of the most active and distinguished members of the Profession from entering the Poor-law Medical Service at all. Hence, one very important case to which the Workhouse Infirmaries might have been made subservient—namely, the instruction of the rising generation of medical men, has been almost completely ignored; but we are glad to find that Mr. HARDY contemplates the partial application of these institutions to the purpose in question.

The writers in the medical journals, and ourselves among the number, have so often pointed out the distinction existing between the ordinary pauper and the unfortunate disabled victim of accident or disease, that it is quite unnecessary for us to dilate upon this part of the subject, and we are rejoiced to find that the President of the Poor-law Board has at last opened his eyes to view the matter in this light; and this distinction, in fact, is the basis of his proposed legislature, so far as it concerns the affairs of the Medical Profession. What we have so repeatedly urged in the interests of humanity—namely, that disease and infirmity are not the same things as ordinary pauperism, is now acknowledged as an axiom, and the care of the sick, the helpless, and the imbecile will henceforth, if Mr. HARDY's plan should be adopted, be transferred to more competent hands, we earnestly hope, than those to which this important task has hitherto been confided.

The absurd distinction still existing between the parishes placed under the control of the Poor-law Board and those which are governed by local Acts is to be abolished, and by the repeal of those Acts, the mischievous conflicts between the central authority and the Guardians will cease to occur. The whole of the Metropolitan districts are to be placed under the absolute control of the Poor-law Board,

and whatever might have been the murmurs which such a step would have caused in former days, it seems that the bugbear of centralization has lost its terrors, and people seem now to welcome the new Poor-law scheme as if it were the harbinger of liberty rather than an offshoot of despotism.

The new Bill proposes, then, that a line shall be drawn between the ordinary paupers, who are still to be dealt with by the respective parishes and supported out of the local rates, and the sick and insane paupers, who are to be maintained at the expense of the whole metropolis. Assuming the whole number of persons brought thus under the superintendence of the Poor-law Board to be about 34,000, including children, Mr. HARDY proposes to place all the lunatics, estimated at 2000, and 700 or 800 fever and small-pox patients in separate establishments to be provided for the purpose, thus leaving the ordinary workhouses in their present condition, *minus* the fever and small-pox cases, the imbecile, and the children above the age of two years, who are also to be removed to separate schools. The ordinary sick poor, who are not included in the above category, would be lodged in infirmaries placed under separate Boards of Management, and of these Boards one-third of the members are to be nominated by the Poor-law Board from persons resident in the district, rated at not less than £100 a-year. The obvious meaning of this provision is to take a part of the local management out of the hands of the small shopkeepers who at present are often exclusively chosen as Guardians, and to transfer the trust to persons of position and property, and who would be, moreover, under the direct eye of the Board at Whitehall.

It is proposed to establish four Fever and Small-pox Hospitals for the whole metropolis, supported out of a general rate, and this feature of the scheme is one worthy of the greatest approbation. The great danger arising from the existing system of sending fever patients to or keeping them in the workhouse infirmaries has been so often exposed that it needs no comment, and the establishment of such hospitals has been so long and so urgently demanded that it is only extraordinary that they have not been erected long ago.

Another important feature of the new Bill is that the salaries of the medical and other officers will be paid out of the general rate, and thus a great amount of local jobbery will be prevented, and the Medical Officers will occupy a more independent position than they have yet enjoyed.

### Notes on Current Topics.

THE CITY DISPENSARY, LONDON.—This useful charity was instituted on the 1st day of January, 1789, professedly for the relief of the sick and diseased poor, and since that

date has been entirely supported by voluntary contributions. The anniversary festival was celebrated by a dinner at the London Tavern, on Tuesday, the 12th instant, when the Lord Mayor presided. From the report we learn that the premises now occupied will be almost immediately required by the Metropolitan Board of Works for the formation of the new street from Blackfriars to the Mansion House, and as the lease has expired no compensation will be granted. The great rise in the value of property in the city will necessitate a large increase of expenditure, so that the committee feel called upon to make an urgent appeal. Surely such a city as London cannot let one of its oldest charities want for funds. An institution of this nature ought certainly to be rent-free. Considering the time it has been established, money ought to have been accumulated to purchase a suitable site and build a dispensary. We would recommend the committee at once to start a building fund, and so see whether the citizens will not soon endow the charity with a freehold.

The following figures from the report presented at the dinner show what has been done during the year:—

#### REPORT OF PATIENTS.

Patients on the Books 1st January, 1866, 1010; admitted during the year, 11,600; total, 12,610. Discharged, cured and relieved, 11,314; discharged for irregularity, 31; died, 56; remaining on books 31st December, 1866, 1209; total, 12,610.

Upwards of 3000 visits have been made to patients at their own houses, and 860 cases of emergent disease attended without letters, besides choleraic cases—as under:

THE OBSCENE QUACKS.—We are glad to find that the practices of the obscene quacks in thrusting their filthy bills and pamphlets into the hands of the passers-by in our great metropolitan thoroughfares is again beginning to attract attention. In a letter addressed to the *Pall Mall Gazette*, Dr. Forbes Winslow has offered some very sensible remarks upon the indecency of the proceeding, and upon the injury which must be inflicted upon the rising generation by the perusal of the contents of these prurient and mendacious productions, the real object of which is of course to allure the unwary into the dens of the advertising quacks for the purpose of extortion. It is to be hoped that the *Pall Mall Gazette*, which has already done so much for the interests of the honourable practitioners of medicine, will continue to agitate this subject, and the more so, as we learn that legal steps are now being taken in order to put a stop to the distribution of the circulars and pamphlets to which we allude. It is quite disgraceful to our civilisation that the minds of youth should be contaminated by the medium of this moral poison, and it is an anomaly in our system of police that while any obscure and miserable shopkeepers who sell indecent books are punished with imprisonment, the rascals who are gaining large incomes by trading on the vices, the follies, or the fears of the ignorant are allowed to escape with impunity.

**CHOLERA AT JERSEY.**—We regret to hear that this disease has broken out in the Channel Islands. The first cases reported took place on Sunday, the 10th instant. By Tuesday evening, fourteen cases had been reported. The next day eleven new cases occurred, all of which were fatal. Although the majority of the cases have taken place in the worst parts, yet the disease has not been absolutely confined to these. Among the measures adopted to arrest the progress of the epidemic, we may mention the erection of tents by the military, in a healthy locality, to which the families of those attacked can be removed, while their houses are thoroughly disinfected, and the setting apart of a portion of the General Hospital for the reception of the victims of the disease.

**LIFE ASSURANCE AND TRAVELLERS.**—Every young man who has entered the married life and has prospect of a family may have recourse to an Assurance Company, as one means of making provision for those dependant on him. In any respectable and well-established office he may be sure of ultimately securing his object in cases in which he could not do it himself, and at the most moderate expense. The rate of premium for life assurance in these Institutions is based, as everyone knows, on an average of human life, the correctness of which has been tested by a series of years; so that while securing the interests and permanence of the Society, the annual payment of the insurer is not in excess of what it ought to be. But there are certain companies who exact an additional premium if he cross the sea to America, or to any other part of the world except Europe, and fix certain bounds beyond which he is not to pass. The Sun Life Assurance in its directions as to foreign residence, says, "on payment of a small extra premium for the risk of the voyage only, the assurances will be extended to cover the risk of proceeding to and residing in British North America, the United States (east of the Mississippi, and not further south than the latitude of Washington), parts of Australia, New Zealand, the Cape of Good Hope, and Natal." The amount of additional premium is not stated, but we learn from another source, that in the Equitable, the London Assurance, and the Atlas, it is ten shillings per cent.; in the Sun, the Law Life, and the Economic, it is five shillings per cent., while others require no additional premium at all. Now, the question is, on what ground do these officers found their claim to additional indemnity, and impose their restrictions? The premium in every kind of insurance is always considered to be in proportion to the risk. But is there more danger in crossing the Atlantic than in a railroad journey from London to Edinburgh? or, is there more risk in a trip to America, or the Cape, than men are often exposed to in some of the ordinary professions and employments, and amusements of life? Again, as to place, is a man safer in North America, or part of Australia, or Natal, than he would be in the Southern States? or is his life in more peril on one side of the Mississippi than it would be on the other? There seem to be in these matters no certain data, no ascertained facts, no logical conclusions on which these societies can proceed, and the difference in their regulations implies as much. Why should one demand ten shillings per cent. extra premium, and another nothing at all? Whether things should remain as they are, and what effect such uncertainty and disproportion may have upon their Institutions is for them to consider.

**THE ARMY.**—From the Appendix to the Report of the Recruiting Commission, we learn that there were on Jan. 1st, 1866, 77,701 serving at home, 48,806 in the colonies, and 68,042 in India. The casualties in a single year amounted to 23,008—viz., 16,086 discharged, 3519 desertions, and 3403 deaths. Of the 16,086 discharged, 6088 had completed their service, 2276 purchased their discharge, 4950 were invalided, 1960 were permitted to leave by indulgence, and in 812 cases the cause was not stated. To supply this deficiency from casualties in the year, only 14,430 recruits joined the army, and 1010 men rejoined it after desertion; 17,122 of the casualties occurred in the army at home, 3569 in the colonies, and 2317 in India. Taking an average of five years, 1861-5, to 1000 strength, the total casualties were 94—viz., net loss by desertion, 11; death, 17; invaliding, 25; discharged by indulgence, 11; completion of service, 15; purchase, 9; other causes, 1.

**SURGEONS FOR THE NAVY.**—We believe the recent scheme of the Admiralty for subsidising medical students, which called forth such a storm of just indignation, may be considered to be definitively abandoned. The students have proved themselves worthy the noble profession they have chosen by repulsing the insult offered. We know that large numbers would be very glad to enter the navy could terms acceptable to a gentleman be obtained. The Lords of the Admiralty both insult and deceive the members of a liberal profession, and then wonder at the dearth of candidates for appointments in the navy. Let any one of them subject his domestic servants to the same indignities that Assistant-Surgeons have had to endure, and he will soon have the pleasure of waiting upon himself. To say nothing of Jeames and others of equal importance in the household, the youngest errand-boy and poorest scullery-maid would very soon "give warning," and quite right, too! While the Admiralty withholds bare justice the profession must decline to enter the naval service.

**INDUSTRIAL DWELLINGS.**—Labourers and artisans—that is, the working classes, as distinguished from the rest, form a large and important part of the population, to whose health, and convenience, and comfort we are bound to pay attention. They, as a class, ought not to be overlooked, because, though occupying inferior grades, the relation they sustain to the great whole cannot be dispensed with. Take them away, their skill and their toils, and the social chain would be snapped asunder. They have their claims, therefore, as well as the rest of the community, and those claims cannot be disregarded without danger to those around them. Hitherto, we cannot but think, they have been sadly overlooked with regard to their dwellings. While houses have been built in every direction befitting the condition of almost every rank above them, their necessities, for a long time past, seem to have been entirely unheeded. Their very habitations have been pulled down, and they have been left to seek shelter where they best could. Latterly, attention has been aroused to this state of things, by the misery, the disease, and the mortality, which have followed, and which have endangered the neighbourhood. We are glad to notice that in the House of Commons Mr. McCullagh Torrens moved for leave to bring in a bill on this subject. From the information he had received, he considered "matters were getting worse," and that no voluntary efforts could possibly remedy "the want of accommodation

and the amount of misery which resulted from it." He asks the Government to advance one million at three and a half per cent. out of the forty-six or forty-seven millions, the savings of the working classes. This would provide 35,000 dwellings, and the "sum advanced would be charged by way of mortgage on the buildings so erected." From the remarks of Mr. Walpole we hope the Government will encourage the measure, and that ere long we shall see those "fever nests," which now surround our metropolis, destroyed; and instead of them comfortable cottages or lodgings erected, where the industrious, at means within their reach, may live in comfort and cleanliness, near to their employments, and not forced away into the suburbs as they now are.

**KEARNS v. STORKS.**—This case having ended in a compromise, it has been announced by the solicitors of Mrs. Kearns that they will shortly prosecute Sir J. Olliffe, Physician to the English Embassy at Paris, and one of the medical men who signed the certificate that Mrs. Kearns was insane. Here is another illustration of the dangers to which our profession is exposed. If Mrs. Kearns or her lawyers failed to show that Mr. Storks improperly confined her in a lunatic asylum, what possible ground can there be for an action against the physicians who gave their opinion that she was a fit person for such restraint?

**HUNTER'S DAY AT THE COLLEGE OF SURGEONS.**—The forty-third Hunterian Oration at the Royal College of Surgeons of England, was delivered on Thursday, the 14th inst., by Professor Hilton, and those who had the pleasure of listening passed a very profitable hour. There are, perhaps, few men in the profession who might be expected more thoroughly to appreciate the greatness of Hunter's mind than Mr. Hilton, and we can only say that on this occasion he fully came up to the expectations that had been formed. One of the most beautiful illustrations of the value of Hunter's patient truth-seeking spirit was selected by Mr. Hilton to show how immeasurably he was in advance of his contemporaries, even in points on which we have since learned much. We allude to Hunter's doctrine on sympathy, which, in several of its ramifications, was shown to have been but the rough expression of what has since been worked out, or the accurate clinical records of what has since been explained. Mr. Hilton half apologized for the dryness of some of the details he introduced on this point, especially the reproduction of Hunter's diagram of sympathetic action, and the quotation of its explanation. For our part we consider it one of the most valuable parts of the oration, and scarcely less interesting, although naturally less exciting, than the eloquent peroration which drew forth the applause of the crowded theatre.

**THE LUNACY LAWS IN FRANCE.**—A case was lately heard in part at Westminster, but arranged by mutual consent, in which a middle-aged female sought to recover compensation for having been consigned to the Lunatic Asylum of Charenton, near Paris, at the instance of a gentleman who was the son of the late Mr. Sergeant Sterles. As the case terminated somewhat abruptly the defence was not heard, and hardly any medical evidence was adduced. As it is understood that the plaintiff in the above case is to receive a pension for life (a proposition to that effect having indeed been made long before the action was brought) it might have been supposed that the matter

would have been allowed to rest, but it seems by a letter published in the *Times*, that further proceedings are to be instituted against Sir Joseph Olliffe, the Physician to the British Embassy in Paris, who signed one of the Lunacy Certificates. The *Daily Telegraph* expresses its joy that this course is to be taken, but we, in common with most other respectable journals, learn the intelligence with regret. Considering that Sir Joseph Olliffe, Foville, and Calmeil, are all concerned in the case, there can be no doubt, even before the action is brought, of the perfect *bona fides* which must have actuated those gentlemen, but in the present aspect of the matter we can make no further comment.

**CHINESE SUGAR GRASS.**—A letter appeared in the *Times* of Saturday, complaining that the person who offered to send a few grains of this seed for a stamped envelope has not replied to the letter sent by a correspondent; and the *Times* adds a note to this effect:—"We have received at least a hundred letters telling the same tale." Under these circumstances, as we informed our readers of the offer, we think it right to add the "caution."

**PATHOLOGY v. CHEMISTRY.**—An inquiry was held on the 5th inst., at Belfast, into the death of a servant girl who had died suddenly in the house of a solicitor in that town. It appeared that suspicions were entertained that death had been caused by an effort to procure abortion. Dr. Hodges, Professor of Medical Jurisprudence in the Queen's College, reported as follows:—

"Separate examinations were made of the substance of the stomach and portions of liver, of the spleen, of the contents and washings of the intestines, for mineral poisons; but no trace of mineral or saline poison was discovered.

"The stomach and also the contents of the intestines were treated by alcohol and water, and also submitted to examination by dialysis, and to Sta's and other processes, for the detection of the poisonous alkaloids and other organic poisons, but no trace of oxalic acid, aconitine, or other organic poison was detected. The parcels received on the 17th inst. consisted of a large tea-cup. The tea-cup contained two ounce by measure of a slimy, dark-coloured, sour-smelling liquid, stated to consist of matters vomited by the late Ann M'Grady. I found it to contain pieces of wool, lumps of bread, or cake, a common pin, a feather, a strip of black ribbon, and some black thread. The contents of the cup were examined by the microscope, and also by chemical processes, for both mineral and vegetable poisons, but no trace of poison was found to be present.

"The red-coloured liquid contained in the bottle measured one ounce and a-half. It had a fragrant, somewhat aromatic, odour and bitter taste. One half ounce of it was found to contain eleven grains of a yellowish-red extract dissolved in dilute alcohol. The results of a series of examinations of its properties showed the absence of strychnine, aropine, aconitine, &c., and proved that it was not poisonous.

"To confirm the accuracy of the conclusions afforded by the chemical analysis, some physiological experiments were made on rabbits with the extract of the red liquid, and also with the concentrated solution of the matters dissolved from the stomach and intestines of Ann M'Grady. Portions of the extracts were applied to the eyes of rabbits, and also introduced into their stomachs, but no poisonous or other effects such as the poisonous alkaloids produce were observed.

"My opinion, therefore, is that no one of the substances examined by me in this case afford any indication that the deceased died from the effects of poison."

Dr. Hume (Crumlin) was examined, and said that the

deceased was a patient of his in the month of April 1866. He found by his dispensary-book that he had treated the deceased for anasarca, principally swelling of the legs and red spots. The legs were tender and painful. So far as he recollected, she was in general bad health, and there was an absence of the periodical ailments of women. She got better under his treatment.

Dr. Angus M. Porter was examined, and deposed that he made a post-mortem examination of the deceased on the 5th of January. The brain was quite healthy, but there was a slight congestion of one of the membranes. There was a slight diffusion of the investing membrane of the lung; liver congested; lower part of the gullet and stomach inflamed, especially pylorus; duodenum highly inflamed, and containing kyle; large intestines, slightly congested; heart perfectly healthy; spleen congested. The witness was further examined, and swore to the best of his belief that some time previous to her death deceased had been pregnant; but, from the inflamed state of the womb, and other indications, he believed that the womb had been prematurely discharged of its contents.

The Coroner—What do you believe was the cause of death?

Dr. Porter—My belief is that death was caused by an irritant poison.

The jury found—"That the said Ann M'Grady, having received into the system an excessive quantity of some unknown irritant drug, came to her death from the effects thereof, and the jury do say that the said Ann M'Grady, from the effects of the said irritant drug, and not from any other cause, to the knowledge of the jury, did die."

It is probable that the verdict of the jury may open up in a higher tribunal the question of the relative confidence to be placed in pathological and chemical investigation. The evidence of Dr. Hodges is extremely explicit, while that of Dr. Porter as to the post-mortem appearances is equally distinct, and if the observations of both gentlemen may be accepted as equally reliable, the question will not prove easy of solution.

#### HOSPITAL RULES FOR RESIDENT MEDICAL OFFICERS.—

There are three resident Medical Officers in Sir Patrick Dun's Hospital; one for the Apothecary, and two Medical Scholars of Trinity College, Dublin, who discharge the duties of resident pupils. The following are the Rules of the Board of Governors respecting the Resident Medical Officers, passed on the 22nd of January, 1867:—1. One only of the three Resident Medical Officers may be absent from the Hospital at the same time; and such absence shall not exceed three hours in each day. 2. No Resident Medical Officer shall absent himself from the Hospital for more than three hours without reporting the cause of such absence to the Board, or without their special leave obtained beforehand. 3. It shall be the duty of the gate-porter to report the hours at which the Resident Medical Officers return to the Hospital at night. 4. The Resident Medical Officers are not permitted to entertain their friends in the Hospital.

MR. HUMPHREYS held an inquest recently on the body of a child about two years old. The jury returned a verdict of "found dead from blood-poisoning—from want of proper space wherein to live." A man, his wife, and four children had been accustomed to live in a room at a rental of a shilling a-week, and which did not contain sufficient cubical space for the breathing of one adult. The husband and one of the daughters died there within the last two years, and when the cholera appeared in the neighbourhood some time since, it selected the house to which this room belonged for its earliest display.

#### HEALTH OF THE UNITED KINGDOM.

From the Registrar General's quarterly return we select the figures which we think will be most generally interesting to our subscribers.

In the three months of the past year ending the 31st December, the births of 246,519 children, and the deaths of 157,660 persons of both sexes were registered in the United Kingdom. The corrected death-rate of the quarter is 2·163 per cent., which is less than the proportion obtaining in England and Wales alone.

The return for England and Wales shows that the number of births in the same period was 185,010, which exceeded those in the last quarter of 1865 by nearly 6000. This increase was spread more or less over the whole kingdom; the only exception being Cornwall, where there was a striking decrease, caused it is supposed by emigration. The annual birth-rate of the quarter was high, being 3·447 per cent. against 3·322, the mean of the corresponding quarters of the last ten years.

The deaths in the 92 days of the last quarter were 117,187, leaving an increase in the population in England and Wales alone of 67,823, and showing a mean death-rate of 2·184 to 100 of the population, which is lower than the previous ten years' average by ·021, and not higher than the last summer quarter, the prevalence of cholera in East London and different parts of the kingdom notwithstanding.

London and twelve other large towns are thus classified according to the rate of mortality per 1000:—Bristol 21; Birmingham 22; Hull 23; London 24; Sheffield 24; Salford 26; Leeds 28; Glasgow 29; Manchester 30; Edingburgh 30; Liverpool 33; Dublin 34; Newcastle-on-Tyne 37.

The mortality in the country districts of England was lower than in the town districts, the rate of the former being 19, and that of the latter 24 in 1000, but in both below the average in nearly an equal degree.

The Registrar-General remarks that, "the chief characteristic of the season is the diffusion of cholera over the remotest parts of the kingdom, and its restricted ravages everywhere except where the people are living in the open violation of the laws of health." This is saying in other words that, if the recurrence of the evil cannot be wholly prevented, its ravages by proper care may be kept within very limited bounds; but if sanitary measures are foolishly neglected, the consequences to a neighbourhood may be fearful in the highest degree. He mentions various places where the epidemic occurred, in connection with their hygienic peculiarities, and a selection from these will show the justness of his remarks. In London the deaths from cholera were 834, and it is an open fact, of which we need only remind our readers, that the greater number occurred at the East end where the dwellings are overcrowded and unwholesome, and where considerable impurity was found in the water supply. There were 8 deaths in St. Leonard, close to the river Exe, which receives all the sewage of Exeter, and is dammed up by a weir at the fatal point. Brixham, the fishing town at the entrance of Torbay, supplied with bad water, had 30; a small parish in the Crediton district 15; St. George in Bedminster 12. These isolated outbreaks were rendered fatal by local causes. In Chester (Great Boughton) 83 deaths from cholera, 42 from diarrhoea, occurred—the water with singular irrationality having been for some time taken at a point in the river

immediately below the inflow of several of the town sewers. The epidemic caused 30 deaths in the township of Ince, where the water was bad. There were 107 deaths from cholera in Tynemouth, and 27 of diarrhoea, where the hygienic conditions are of the worst description, and the authorities often appear to slumber in the presence of danger. So of Wales, its sanitary condition is rapidly deteriorating, and the deaths by cholera are proportionally great. In Tredgar district 82 died from cholera; in Ystradyfodwg 24; in Aberdare 29; in Ystradgunlais 50; in Llangafelach 31; in Swansea 55; in Holyhead 25.

These are instances of the sad consequences of indifference and neglect, while, on the other hand, as is remarked, "the returns contain many examples of the efficacy of hygienic measures, and afford strong proofs of the doctrine, that if England has suffered less from cholera in the present year than the Continent, or less than England herself in former years, it is mainly due to changes which all Europe can appreciate and adopt. Among other instances, the Black country as it is called, about Wolverhampton, may be cited. The epidemics of 1849 and 1854 destroyed in five districts more than three thousand lives, while in 1866 the mortality has been inconsiderable. The water was formerly impure, and could only be obtained with difficulty in a country covered with pits and works. But the people with commendable energy have brought good waters from a distance, and are reaping the advantages of the change in Wolverhampton, Bilston, and the other towns."

A reference to the "Registrar's Notes," from which we might make some striking selections, would further corroborate these facts, which he presents to the whole nation. We shall simply remark, as we have done before, the wisdom of immediately paying prompt attention to his suggestions, and the folly of disregarding them until aroused by the scourge which our negligence may be instrumental in bringing upon us.

We quote as follows from Mr. Glaisher's remarks on the weather during the quarter at the Royal Observatory, Greenwich:—"In October the mean temperature was  $51^{\circ}3$ , which was higher than any year since 1863. The mean temperature of November was  $44^{\circ}3$ , being  $1^{\circ}5$  below that of last year. That of December was  $42^{\circ}9$ , being higher than any year since 1863, when the temperature was  $43^{\circ}2$ . The mean high-day temperature for October was below the average to the amount of  $0^{\circ}5$ , and those for November and December were above the averages to the respective amounts of  $1^{\circ}3$  and  $2^{\circ}3$ . The mean low night temperatures for the three months were above the averages to the respective amounts of  $1^{\circ}6$ ,  $0^{\circ}5$ , and  $1^{\circ}7$ . Consequently the days were cold and the nights warm in October, but the days and nights were both warm in November and December.

## Correspondence.

### THE PURIFICATION OF WATER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the review of Dr. Saunders' "Report to the Diseases' Prevention Committee of the City of London Union on the Causes and Prevention of Cholera," which appeared in the number of the *THE MEDICAL PRESS AND CIRCULAR*, of 6th inst., I read the following sentence:—"He, Dr. Saunders, examines both the water and the air theories, evidently leaning to the former; and he expressed a fear that we must abandon the hope of rendering impure water fit for drinking by any of

the common processes of filtration through charcoal, boiling, or the use of Condry's Fluid."

Having referred to the report in question, it seems to me that you have misinterpreted Dr. Saunders' meaning. The terms in which he refers to the subject are these:—"It has been alleged that the process of boiling renders these germs (of disease) inert, and such was my own impression when, in a former report, I recommended that the poor should be so instructed; but we are assured by Dr. Frankland, that such a proceeding is not sufficient to destroy them. . . . I fear, therefore, we must abandon the hope of rendering impure water fit for drinking purposes by the simple and inexpensive process of boiling, although, perhaps, this in addition to filtration through animal charcoal may suffice to remove many of the grosser impurities caused by the suspension of organic matter; and the potability of such water may be further guaranteed by the addition of a few drops of Condry's Fluid"—pp. 15-16. And again, (pp. 22-23):—"With organic matter held in solution by water in a state of decay it is different, for there can be no doubt that we possess the means of at once oxydising and rendering it inert; and the simplest mode of accomplishing this on a small scale is by filtration through a layer of animal charcoal and the use of permanganate of potash (Condry's Fluid.)"

It is, therefore, evident that Dr. Saunders, so far from throwing doubt on the efficacy of Condry's Fluid for the purification of water contaminated with organic matter, has stated in his Report, that although the mere boiling of water cannot be relied on to render innocuous water tainted by organic impurities, the use of Condry's Fluid effectually frees water from decomposing organic matter in solution, and at the same time affords the best means known of guaranteeing the potability of water containing suspended organic germs, which filtration may have failed to remove.

I may add that the proof of the soundness of those views is every week placed before the public in the shape of the analysis of the metropolitan waters which appears in the newspapers, for the substance used to determine the amount of organic matter is permanganate of potash, which if ineffectual in destroying organic matter could not be relied on as a test. Every operation of testing water for organic impurities by means of permanganate of potash implies the destruction of such matter, and hence the purification of the water operated upon; and consequently constitutes a demonstration of the efficacy of Condry's Fluid, which is a solution of alkaline permanganates, and the form in which the permanganate water-test was first introduced, ten years ago, by, yours obediently,

H. B. CONDY.

### ON NATURAL AND ARTIFICIAL ELECTRICITIES AS THERAPEUTIC AGENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a recent article inserted in the fifth number of your journal, Mr. Sandham invites the co-operation of gentlemen acquainted with the science of medical electricity, in order to elucidate the subject, and communicate to the profession the result of their experience and researches. I quite coincide with the author in thinking that professional men should by all means assist each other in the diffusion of every kind of knowledge which may contribute to the relief of suffering humanity.

Acting upon this principle, it is now more than ten years since I invited, in some 10,000 copies of various publications, the members of the faculty to visit my establishment, offering at the same time to initiate them into my mode of practice. I also contributed several articles to the *Electrician*, but the editor thought well to curtail my articles of those portions which did not meet his own views on the subject. That gentleman tried to form a special establishment in which he should have obtained the first rank: but the journal and the establishment have both failed long since. So it is, and so it will be, as long as we are content to follow the beaten track of our predecessors. I have now been engaged for about thirty years in the study of medical electricity, during the last fifteen of which I have made a special practice of its application. At the outset I was in the same position as Mr. Sandham—i.e., ignorant of its proper mode of application. I searched, I read, and consulted wherever I could, but found nothing but uncertainty and confusion upon the subject.

Even now, when the science has made great progress, through the labours of eminent men of merited reputation, the student is embarrassed in his choice among the conflicting opinions of so many different masters.

For example, Dr. Duchesne de Boulogne, a surgeon of acknowledged skill and ability, the author of a very elaborate work of nearly 1000 pp., who has discovered the action of certain muscles, and obtained many cures, by the means he employs, confines himself to what he terms "faradization," as the only agent to be used. When I spoke to him of other applications, he ridiculed the idea. On the other hand, M. Beckensteiner (whom I visited at Lyons), has adopted, as a special means, the static electricity produced by the electric machine. I have seen him operate, and have conversed with his patients. Many of them had benefited by his treatment, and some had been cured. This gentleman has also written a very able work upon his system; but he admits of the application of no other electricity than that obtained from the wheel.

Other professors again have chosen the continued current from the pile, while others adopt the single current of the electro-magnets, and some the magneto-electric, the reverse of the former, as the only rational mode of practice. Thus it happens, that there is no canon or law to guide the student in the study of electric science, unless he follows the advice of Dr. Bover Dodds, of America, the author of a treatise on Psychology, and Animal Magnetism, who says that the only safe system to be adopted is the electric, or one composed of the best portions of all other systems. This is the course which I have followed myself.

As every kind of electricity has a peculiar action, and each possesses a distinct physiological virtue, it becomes necessary to apply them accordingly to the nature and character of the disease which we have to treat, and the various effects which we desire to produce.

This agent, however, which is the active principle of all the vital phenomena of nature, and whose immense powers are incalculable, may be converted into a dangerous weapon if not properly applied. It would, therefore, be most desirable that electricity should be included as a *sine quâ non* in the programme of medical studies; and, better still, if it were introduced into hospital practice. To effect this we require a public school where students could be instructed in the principles of the science and in its practical application.

There are many in the profession who, though they have not studied the subject themselves, are aware that electricity does afford the greatest resources as a therapeutic agent, and would be desirous to apply it as such, if they only knew how. As it is, they are in the position of a person in whose hands you place promiscuously a variety of remedies, telling him that he possesses therein the cure for many diseases, to go therefore and heal the sick.

It may be said, however, that electricity has been employed successfully by many who were not acquainted with its therapeutic properties or physiological action. This may be so, and it is to a certain extent true of all empiricism; though we must not forget the larger proportion of patients who suffer from misapplication and maltreatment at the hands of the unskilled and ignorant.

Of these many have passed under my own treatment, and they ask me why has electricity failed with them? Electricity is produced by natural laws, and is, the same in the hands of every one. It is not the agent itself, therefore, which fails, but the mode in which it is applied.

What is that mode, and what knowledge is requisite for its correct administration?

This knowledge is clearly two-fold; first of all, he must be able to diagnose the pathological condition of the organ which is diseased, and be conversant with anatomy, splanchnology, and physiology. Secondly, he must have made himself familiar with the characteristics, the properties, and *modus operandi* of the two species of electricity, and have acquired a practical knowledge of their various modes of application, for these constitute, so to speak, the *materia medica* of the electrician. The effects of electricity are so manifold that it may be said to be an armoury in itself against every disease, and, in a word, a universal panacea. It is an incomprehensible power, but, like the sun, we cannot comprehend it. It is the vivifying principle of the universe, but we know both only by their effects. If it would not occupy too much space, I would, with pleasure, give, as an illustration, the record of a series of cases successfully treated by electricity, the various methods which I have adopted for its application, and the implements also requisite for its application. These are—the copper bath, with various conductors for local applications; an electric machine, with all its appendages; electro-magnets, single and double currents; electrodes appropriated to the various organs, such as the eyes, ears, mouth, and all other parts of the organism;

which, with other appliances, form an arsenal thoroughly furnished to meet every kind of foe in the shape of disease.

Perhaps Mr. Sandham will pardon me if I take the liberty of observing that he himself omitted to describe the manner in which he applied the electric current in the interesting cases which he gives. I beg, also, to differ with his opinion with regard to the nature of the hemiplegia which he treated. I should certainly classify it as a case of *paralysis*, as paralysis signifies the loss of action or motion, whatever may be the cause which has produced it. The causes may, indeed, be various, and present diverse phenomena. It is essential, of course, to discover what those causes are, as the cure depends entirely upon their removal.

J. F. CAPLIN, M.D., F.A.S.L.

## MEDICAL ACT'S AMENDMENT BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reading over the proposed Medical Act's Amendment Bill, one cannot help thinking that it is still very inefficient for the thorough and legal protection of the rights, privileges, and interests of the members and students of the medical profession.

*In the first place*, Clause XVI. of the new act is still very ambiguous. It appears from reading it that any person may practice medicine and surgery still, providing he assume not the title of physician, surgeon, &c.; at least, I fancy the law would try to make it so in case of prosecution under this said Clause.

*Secondly*, Should Clause XVI., though after all, prove in reality so thoroughly effectual, that all persons practising medicine and surgery, not registered, can be prosecuted and convicted, what is to be done with artied pupils and assistants engaged in the treatment of diseases for the interest of their principals and students, on account of the hospital or dispensary to which they may be attached; also in the cases of midwives, qualified or not, rendering assistance in child-bed to the poor who cannot fee a duly qualified medical man? I repeat, what is to be done in any of the above cases? for should Clause XVI. prove all that can be desired, then assistant, student, and midwife will all be open to prosecution alike. Surely a special clause must be added for their protection.

*Thirdly*, It is scarcely fair to British (by British I mean English, Scotch, Irish, and Colonial) qualified medical men, that foreign graduates in medicine should be entered on the Medical Register, and allowed to practice in any part of the British empire, and to enjoy equal rights and privileges with the British practitioner without first being examined by a Board of examiners appointed by Government, and then, if passed, such foreign graduates to agree to practise medicine and surgery, subject to certain bye-laws—say those as the Royal College of Physicians of London require their licentiates to observe.

I do not think the above hard or interfering with the liberty of the subject, as it is a fact on the Continent that Englishmen before practising there must obtain not only permission of the Government to do so, but in some cases they must also possess the M.D. of certain Continental Universities. In conclusion, let me observe—using an old adage—"that what is worth doing at all is worth doing well." So it becomes the duty of those to whose lot the framing of the Medical Act has fallen to make it as stringent and as efficacious as possible for the thorough suppression of quackery, and the illegitimate practice of medicine and surgery in all its branches. It is high time that the public should be able to distinguish and know the difference between the qualified and unqualified practitioner; or rather that a certain portion of the public should not have it in their power to consult the knave in the garb of the honest man. Let an act be obtained that can bring the quack and impostor speedily to account and conviction, and the public will be quite as thankful for it and reap as many benefits as the members of the medical profession themselves.

HENRY W. WILLIAMS, L.R.C.P. Edin.

QUARANTINE on arrivals from Ireland with clean bills of health has been abolished at Malta.

THE Board of Guardians of the Ennistymon Union, Co. Clare, have increased the salaries of their medical officers, Drs. Shannon, Coleman, and Ryan, from £80 to £100 per annum; and the Poor-law Commissioners have sanctioned the increase.

## MEDICAL GLEANINGS.

(From the British and Foreign Medico-Chirurgical Review.)

## ON THE INJURIOUS EFFECTS OF DRESSINGS AFTER AMPUTATIONS.

DR. BUROW brought this subject before the profession in 1849, with the object of showing that much of the mortality that follows operations is really due to the employment of dressings. He adduced the slight mortality that had attended his own cases in which these were abstained from as compared with that exhibited by Pauli's statistics. He is now enabled to refer to an additional number of his own cases, making ninety-four altogether, in which the mortality has proved quite trivial. And yet these include numerous cases of amputation of the thigh, leg, arm, &c., many of the patients upon whom the operation was performed being very poor, and treated under disadvantageous sanitary conditions. The stumps in all, however, were left freely exposed to the air, unincumbered with dressings.

As to the execution of the operations, Dr. Burow, when possible, always prefers the tourniquet to manual compression, and performs flap operations whenever the condition of the soft parts admit of this. He disapproves of shaving off the periosteum before dividing the bone, and is very particular in tying every bleeding vessel, believing it far better to tie some of these superfluously than to have the stump disturbed by subsequent bleeding. The surface of the stump is to be left quite exposed until a serous exudation begins to issue, which is generally the case within half an hour, although in some cases we may have to wait some hours for this. The flaps are then brought together by means of two or three sutures and three or four strips of adhesive plaster, these last sufficing without the sutures in amputation of the arm. After the patient has been placed in bed the stump is only covered with a piece of linen to protect it from the flies, and in the case only of there being much pain ice is resorted to. The very great swelling which takes place in the stump during the second and third days is evidence of the mischievous effects which must result from its confinement by dressings. By Dr. Burow's plan nature is left unimpeded in her process of restoration of collateral circulation of the divided vessels, and emboli with pyæmia are far less likely to occur. If the swelling of the edge of the stump be very great, the threads may be divided at their points of insertion and left to be discharged, the adhesive plasters being renewed when they become loosened. The discharges are to be gently pressed out from the deeper portions of the wound, and the greatest attention must be paid to cleanliness. How much less reaction follows this simple procedure is seen by the rapidity of the recoveries, patients who had undergone amputation of the thigh having repeatedly left their beds on the eleventh day, the stump being guarded by a small pledget kept on by adhesive plaster. For some years past Dr. Burow has been in the habit of applying to wounds attended with abnormal discharges the acetate of aluminum lotion, which is a cheap and excellent preparation for hospital practice, removing all bad smell. So after amputation, when the discharge is considerable he resorts to it.—*Deutsche Klinik*.

## ON CATARRHAL INFLAMMATION OF THE CAVITY OF THE TYMPANUM OCCURRING IN YOUNG PERSONS.

DR. ROOSA in this communication refers to one of the forms of catarrhal inflammation of the tympanum which proves very amenable to treatment. It may come on without any positive exciting cause, more or less impairment of hearing gradually taking place, with little or no pain.

"Objectively, the following symptoms are observed:—The pharynx is found in a state of inflammation; little elevations, like granulations, are seen on its surface, and the secretion is in excess. The tonsils may or may not be hypertrophied. The membrana tympani, instead of having its normal 'neutral grey' colour, is of a pinkish hue, with an exceedingly brilliant appearance. The vessels are not generally to be distinctly traced on any part of it. The triangular light spot is either entirely absent or is smaller than normal, indicating that the position of the drum is changed.

"The observance of hygienic rules, the exhibition of various therapeutical agents, and due attention to the condition of the mucous membrane of the pharynx, will in time bring relief in

these cases, but the impairment of hearing is a symptom which long remains troublesome. We have, however, the means at our hands, in Politzer's method of rendering the Eustachian tube pervious, of instantly improving the hearing, thus removing the most embarrassing symptom, while we go on with the proper general treatment, curing the disease on which this symptom depends. It may be supposed that the impairment of hearing in these cases is due to a plugging up of the faucial orifice and the calibre of the tube by mucus, which is suddenly expelled by the column of air driven in. . . . It is confidently asserted that the use of Politzer's method in the treatment of this class of patients will render the progress of the case highly satisfactory, which under the old method could hardly be said to be the case. After the first use of the instrument the improvement which occurs will probably only last a day or two, but I have never known the hearing to have become worse, and the repeated (say three times a week) practising of the method will render the improvement permanent. It is only an adjuvant, a fact carefully to be kept in mind; and the necessary general treatment should never be lost sight of. I was led to the attachment of a bulb or inhaler containing tincture of iodine to the simple apparatus of Politzer, from the need felt of introducing some substance into the cavity of the tympanum which should promote absorption in the mucous membrane of the tube and middle ear. This want is supplied by the introduction of the iodized air; and my experience serves to show that the combination produces a more powerful and permanent effect than is produced by the use of simple air."—*American Journal of Medical Science*.

## ON REDUCING DISLOCATIONS BY MEANS OF CAOUTCHOUC.

M. ANGER observes that, having for some time employed this substance in the treatment of ankylosis, fractures, spontaneous dislocations, &c., the good results derived from it induced him to extend its application to traumatic dislocations. A man was brought to the clinic with dislocation of the shoulder, which the ordinary procedures failed to reduce. The trunk being secured, extension was applied by means of a tube of caoutchouc, the thickness of the little finger and sixty centimètres in length. Gently employed at first, the traction was gradually increased until the tube had been wound four times around the bed-post, thus making four traction cords of fifteen centimètres each. The extension was kept up for nearly half an hour, the patient by that time feeling quite exhausted; and the muscles which had resisted the reduction having become relaxed this was easily accomplished. This mode of making the extension by its gradual and gentle, though efficient, character, M. Anger considers as very superior to any of the ordinary procedures. The amount of traction employed must be proportioned to the resistance offered, which varies by reason of strength, sex, and age. In the present case, the subject of which was athletic and the dislocation complicated, four tubes, fifteen centimètres in length, extended to double their length, amply sufficed. The extension should be regulated in ordinary cases so as to obtain complete muscular relaxation in fifteen or twenty minutes.—*Gazette des Hôpitaux*.

## ON AMPUTATION OF THE HIP-JOINT.

DR. MORTON in this paper gives the histories of the eleven cases of this operation which have been performed at Philadelphia. Of these, seven recovered and four died. He terminates it with the following conclusions:—

"1. In cases of long standing disease, tumours involving the bone, soft parts, or both, necrosis following gun-shot wounds, reamputations, or where suppuration has existed for a long period, the constitution being more or less accustomed to the drain and irritation, a more favorable result after amputation may be expected than in those cases where the operation has been performed for recent injury, where it has almost invariably proved fatal.

"2. In regard to the choice of operation, the integumentary flap operation, with a circular division of the muscles close to the pelvis, may be considered a safer operation, and is preferred to all others by Professor Pancoast. By this there is not so much muscular tissue left to suppurate, and we have more reasonable hope for primary union to a considerable extent. In small shrivelled limbs, where there is hardly any tissue about the joint except skin, the flap operation is probably as good.

"3. The loss of blood during the operation being primarily the chief source of danger, we find the abdominal tourniquet absolutely required, and no operation at the joint should be undertaken without it. Having the control of the circulation throughout the extremities, we are able to guard against all loss of blood, which otherwise might tend to develop pyæmia, or even immediately to allow of a fatal collapse.

"4. The after treatment of the stump by the application of *pure laudanum* (the parts being constantly wet with it) was first used by Dr. Pancoast in 1860, and answered admirably. In his second case he was able to put the patient asleep at any time by increasing the quantity used, more than a gallon being used in his last case. This dressing was employed in the case which came under my care, and answered every indication."—*American Journal of Medical Science*.

#### ON SPRAINS IN CHILDREN.

M. GUERSANT recommends that cases of slight sprain should be treated either by binding wadding around the joint, or by methodical kneading or shampooing (*massage*). This last may be resorted to either immediately or some hours after the accident, provided always that there be tumefaction and infiltration of the soft parts, a bandage moistened with a spirit lotion and a little extract of lead being afterwards applied. The hands having been greased with lard, gentle and prolonged pressure should be exerted on the limb from below upwards, the *séances* being repeated more or less often according to the severity of the sprain. In slight cases the patient is enabled to walk after one or two of these; but when the sprain is more severe, the shampooing may have to be repeated for several days. Where there is great swelling and severe pain leeches should be resorted to; or cold may be kept applied by means of wet compresses or continuous irrigation. At the end of a few days a bandage should be lightly applied, to be followed when the swelling has all subsided, by a starch bandage, which may be retained for a fortnight, month, or even longer.

M. Guersant especially alludes to the sprains produced in children by the mischievous practice of suddenly raising them by a single arm, the limb always being more or less twisted into a state of pronation or supination, with distension or stretching of the joints at the wrist and elbow taking place. It is very rare for fracture or dislocation to be produced in this way, but the appearances may be such as to cause alarm to the friends of the child, and sometimes even to the medical attendants. In ordinary cases, there is no appreciable deformity present, but the movements of the parts give great suffering to the child, and on the execution of these a sound is sometimes heard, without seeming to proceed from any precise spot, such as might be produced by the sliding of articular surfaces on each other. Quite suddenly, after the execution of some of these movements, the child ceases to complain; and without our seeming to have done anything to remedy the defect, he becomes enabled to move the arm as before the accident. Sometimes, however, the pain persists, and there may be great tenderness around some one of the articulations. It is not always possible to make a correct diagnosis in these cases; but when neither fracture or dislocation can be detected, a sprain may be said to have been produced—*i.e.*, a sliding of the articular surfaces with distension of the ligaments; or, in other words, a tendency to a dislocation which has not been effected. The accident is not always confined to the wrist or elbow, and may implicate more than one joint. The arm should be kept at right angles, either in supination or pronation according to the preference of the patient. The child then complains no more, and in three or four days is cured. If at the end of this time pain persists, a starch bandage may be applied for eight or ten days.—*Bulletin de Thérapeutique*.

#### THE ST. PANCRAS WORKHOUSE.

At the weekly meeting of the St. Pancras Board of Guardians, Dr. Markham, Medical Poor-law Inspector, attended in consequence of a communication which had been made to the Poor-law Board on the subject of small-pox cases in the wards of St. Pancras Workhouse. He had just examined those wards, and he scarcely ever saw wards in a more unsatisfactory state, more calculated to spread the disease. He understood there had been not less than sixteen cases in the house since the 9th of November last, and he found that, with regard to clothing, not only had no steps been taken for its disinfection, but they were tucked under the beds of the patients, and allowed to remain

there till the patient recovered. They were then given them to put on. He found that the sheets and blankets were not changed, and the nurse had informed him that very often patients were put under the sheets and blankets that had just been used by other patients, and that she had to get the sheets and blankets as best she could. The same remark applied in cases where persons had died. The things they had used were used again without being disinfected. He had ascertained that there was only one nurse in the wards during the day, and during the night only one old woman, who was 71 years of age. There was only one night-stool for each ward, and if more than one patient required it at once they had to go across a stone yard. He could not help saying that this state of things was most dangerous, and he could not tell to what extent the disease had been propagated in the wards by it. That day there were thirty-seven cases in the wards. He thought it would be better for the Board to take immediate steps to remedy this state of things than to wait for any direct application and investigation by the Poor-law Board. The chairman, Mr. Watson, and other members of the Board called Dr. Markham's attention to the fact that by deputation and otherwise they had frequently urged upon the Poor-law Board the necessity of providing hospital accommodation for small-pox cases. Dr. Markham said he had understood that was the case, and he had no doubt they gave all the accommodation in their power. What he complained of was the system which allowed the wards to run into the condition in which he had found them. Mr. North said if he was ever surprised at anything in his life, it was at the statement with respect to their sheets and blankets, for they were articles of which there was a superabundance at the disposal of each ward. He was equally astonished at the statement that the clothes were allowed to remain under the beds. It was only another instance of the shocking weakness of the present management of their workhouse. Other members of the Board expressed their surprise at the statements that had been made, of which they had no previous experience. Dr. Markham said if gentlemen doubted his word they should accompany him to the wards and he would show them that what he had stated was correct. A resolution was then passed to at once appoint more nurses and refer the whole matter to the House Committee to remedy the evils complained of by Dr. Markham.

### Parliamentary Intelligence.

HOUSE OF COMMONS.—FEB. 12TH.

SCURVY IN THE MERCHANT SERVICE.

Mr. TRACY asked the President of the Board of Trade if his attention had been called to the circumstance that on the 9th inst. eleven seamen were hoisted helplessly on board the *Dreadnought* Hospital Ship in a state of utter prostration, from the easily preventable disease of scurvy, whilst others had been received the same day suffering in a less degree from the same malady. And whether steps had been taken to ascertain the number of British seamen suffering in a greater or less degree from scurvy at the home ports, who had taken refuge in sailors' homes, and in lodging-houses apart from the seamen's hospitals; also at the colonial and consular ports, and in the Indian and Pacific ports.

Sir S. NORTHCOTE said the attention of the Board of Trade had been directed to the case of these men, and he might mention that it had been the practice of the Board of Trade for some time past to direct the shipping masters at the different ports to report to them the cases of seamen landed ill of scurvy. They had no special information as to the number of those sailors who became inmates of refuges or sailors' homes and lodging-houses. In many places inquiries had taken place, and the result of several of them had been laid before Parliament during last Session, and some further papers on this subject which were being prepared with reference to more recent inquiries would shortly be laid before Parliament. With regard to colonial and consular ports, they had not the same means of obtaining information, but there had been a great deal of correspondence with the Indian Government upon the subject, and

papers with reference to it would be laid before Parliament, and the Government hoped before long to introduce provisions to meet these melancholy cases, and apply a stronger control over the causes which led to the prevalence of scurvy.

## Medical News.

**APOTHECARIES' HALL.**—The following are the names of the gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, February 7, 1867:—

Hebert William Fagge (Guy's Hospital), Hythe, Kent.  
On Thursday, February 14:—

William Davies (University College), Llanpumsaint, Carmarthen, Charles Henry Fernivall, Westminster Hospital; John Latham Rushton (Manchester Medical School), Macclesfield; Richard Careless Sanders (London Hospital), Moulton Vicarage, Northamptonshire; Frederick William Fowke (Guy's Hospital), Byfield, Northamptonshire.

As Assistants:—

William Jones, Whitehouse, Lyth-hill, near Shrewsbury; Alfred Henry Buckett, 5, Liverpool-street, E.C.

The following gentlemen also on the 7th of February passed their first examination:—

Charles Lewis, Guy's Hospital.

On the 14th of February:—

Charles Howard Orfeur, King's College Hospital; Walter Williams Godfrey Stables, St. Bartholomew's Hospital; George Andrews and Charles Higgins, Guy's Hospital.

**ARMY MEDICAL DEPARTMENT.**—The Director-General of the Army Medical Department presents his compliments to the editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the candidates of her Majesty's British Service who were successful at the competitive examination in August last, and who have passed through a course at the Army Medical School, showing the combined results of the examination:—

16th February, 1867.

**THE HUNTERIAN ORATION.**—The Hunterian Oration was delivered to a crowded audience, at the College of Surgeons of England on Thursday afternoon, by Mr Hilton, F.R.S.

The forty-sixth annual meeting of the Seamen's Hospital Society was held on Wednesday week, at their offices, 86, King William-street, London, under the auspices of Sir William Bowles, K.C.B. From the report of Mr. Kemball Cook, it appeared that 1500 cases of scurvy were received into the *Dreadnought* during the last sixteen years.

SIR LAURENCE PALK, Bart., at the annual meeting of governors of the Torbay Infirmary and Dispensary, paid a compliment to the manner in which Dr. Powell, the house-surgeon, had performed the onerous duties of his office during the year:—"They had all heard (said the chairman) with pleasure the compliment paid to the doctor, and they were all perfectly aware that he merited that distinction. And he begged leave to tell the doctor that he thought, considering that he had been there comparatively so short a time, it was the highest compliment he had ever heard paid to a

young medical man on his management of such an institution as that infirmary. He said that because he trusted that it would give him zeal and courage to persevere in the good work as he had hitherto done, and to show him that he would find friends and admirers who would always come to his assistance whenever their services might be contributed to his benefit."

**ROYAL INSTITUTION, LONDON.**—Last week, during a lecture upon sound, at the Royal Institution, Professor Tyndall exhibited for the first time a clever experiment devised by Biot, the French philosopher. By means of a polariscope made of rhombs of Iceland spar, placed in front of the electric lamp, the light was so polarised that none of it fell upon the screen. He then fixed a strip of thick plate-glass, about three inches wide and six feet long, in a vice, and, by rubbing it with a wet cloth, made it give off a musical sound, because of the longitudinal vibrations set up. The vice bit the strip exactly in the centre, and there the strain and pressure of the musical vibrations were consequently greatest. But glass under strain or pressure, when introduced into the polarised ray, will let light pass through the polariscope. Consequently, when the ray was allowed to traverse this slip of glass near its centre, a broad disc of light appeared on the screen every time the glass set up a musical sound; but when the strip was at rest the calcareous crystals would allow no light to pass.

**A PROVOST AND TOWN-COUNCIL FINED.**—On Monday week, John Whitelaw, Provost of Dumferline, was charged with, on the 27th and 28th of December last, unlawfully digging up 30 diseased animals, or the carcasses thereof, from a park on the farm of Craighulcar, which carcasses had been buried there in consequence of the animals having died of or been slaughtered while labouring under rinderpest in January, 1866. The provost pleaded "Guilty," in so far as he ordered the exhumation, but stated, in mitigation of penalty, that the ground in question had been acquired by the town in order to increase the storage of water for the inhabitants, and that it was after the purchase they discovered that the cattle had been interred in the place where they proposed to construct a reservoir. They had consulted Dr. Stevenson Macadam as to the best means of removing the carcasses without risk or injury to the neighbourhood, and acting on his advice, and under his superintendence, they had lifted and reinterred the carcasses at a very short distance off, the men employed being kept aloof for the day from all external contact, and their clothes and all the implements and apparatus used being thoroughly disinfected, while showers of water and carbolic acid were sprinkled on the carcasses during removal. The town clerk appeared for the defender, and put in Dr. Macadam's report, stating that the careful arrangements therein prescribed had been strictly attended to. Sheriff Mackenzie said he considered that the proceedings taken in the removal of the carcasses showed, not ignorance, but full knowledge of the order contravened. It was of great importance that the supply of water to Dumferline should be sufficient, but the course for the Town Council was to apply to the Privy Council, or, failing them, to the Legislature, and not to take the law into their own hands. He was happy to think that no evil consequences had ensued, the operation having been carried through very successfully, but the law must be observed, especially by those who were in authority, who ought to show a good example of obedience to the community. He would impose the mitigated penalty of £30, being £1, for each carcass disinterred.

**THE LONDON SICK POOR.**—At a meeting of the Committee of the London Workhouse Infirmary Association (Earl Grosvenor, M.P., in the chair) on Monday, when there were present Lord Charles Bruce, M.P.; the Hon. Dudley Fortescue, M.P.; Mr. Julian Goldsmid, M.P.; Mr. Arthur Mills, M.P.; Mr. Briscoe, M.P.; Sir Walter James, Mr. Henry Goshen, Mr. J. C. Parkinson, Dr. Rogers, Dr. Austie, Dr. Carr, and many other gentlemen, Mr. Hardy's new Bill was considered. It was moved by Mr. Ernest Hart, and seconded by Lord Charles Bruce, M.P., and carried unanimously, that "This committee recognizes with great satisfaction that the Bill introduced by Mr. Hardy embodies literally the greater number of suggestions which they had laid before Mr. Villiers and Mr. Hardy for the better management of the workhouse infirmaries, and of the better treatment of the sick. They regret that he has not been able to place a larger number of the sick upon the common fund, with a view to relieve to a greater extent the poorer parishes, and they entertain doubts as to the successful working of the proposition for adding a proportion of unpaid nominees to the Guardian

Boards." On the proposition of Dr. Austie, seconded by Mr. Briscoe, M.P.; Earl Grosvenor M.P.; Lord C. Bruce, M.P.; the Hon. Dudley Fortescue, M.P.; Mr. Davenport Bromley, M.P.; Mr. Julian Goldsmid, M.P.; Mr. Oliphant, M.P.; Rev. Mr. MacGill. Dr. Carr, Mr. J. C. Parkinson, and the honorary officers were nominated a sub-committee to examine the clauses of the Bill, and report to the association before the second reading.

**WOOD NAPHTHA.**—The principal of the Inland Revenue Laboratory, reporting on the fraudulent use of wood naphtha in the preparation of beverages under various names, says:—"Methylated spirit was, I believe, first sold as a beverage under the name of 'Indian brandee,' a title which alone almost proves the real object of its sale. Next was introduced 'medicated whiskey,' 'pure Islay mountain,' and others, the names of which were more suggestive of the gin palace than of the druggist's shop. Their unequalled valuable properties were widely made known through a profuse circulation of handbills and by other means. Persons went about the country pressing small shopkeepers to become retailers of the spurious article, and I have no doubt that throughout the whole of these transactions there was a tacit understanding among all concerned that the liquids should be asked for and sold as a medicine, although meant to be consumed as an ordinary stimulant. The spurious compounds, under whatever name they were sold, had no definite composition, the only substance which was constantly present, and which, in combination with water, formed nearly the whole bulk, being methylated spirit, or a derivation from such spirit. The 'Indian brandee' was put forward as a specific for nearly every disease, and was said to be composed of the most costly and rare productions of India, which had by great skill been so combined and applied as to become a perfect boon to the human race. It is sad to reflect upon the unblushing audacity of such statements, made by persons who deem themselves honest, and who would resent the application to them of the word impostor, but it is far more so to think that there are large masses of the labouring classes in this country, who firmly believe them. As a corollary to the above, it may not be amiss to state that each of the samples sold as 'Indian brandee' analysed during the past year was composed of either one or other of the following groups of substances—First, Methylated spirit partially purified by treatment with nitric acid and distillation, containing a trace of sweet spirit of nitre, and sweetened with brown sugar. Second, Methylated spirit slightly flavoured with rhubarb, and sweetened with brown sugar. Third, Methylated spirit simply sweetened and coloured. Fourth, Methylated spirit containing a small quantity of chloroform, and coloured. Fifth, Methylated spirit with a small quantity of opium. Sixth, Methylated spirit, coloured, sweetened, and slightly flavoured with ginger. Seventh, Methylated spirit, flavoured with fennugreek, and coloured. Several samples of 'whiskey' were analysed, and, with the exception of not being coloured, found to be identical with the first group of ingredients given above. Two samples of 'Indian tincture' were also examined; one was composed of methylated spirit, containing a trace of sweet spirit of nitre, and much sweetened with treacle, the other was nothing more than methylated spirit similarly sweetened."

## Notices to Correspondents.

Dr. Hearn, Southampton.—Owing to great pressure on our space we are unable to find room for the communication sent us. Shall be happy to give attention to the subject in our next if you can furnish us with early information.

M.D.—Proofs shall be sent you.

Dr. H. J. is thanked for his communication.

Dr. C.—The matter shall receive consideration.

### ASPHYXIA FROM CARBONIC ACID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In reply to your questions appended to the article headed "Asphyxia from Carbonic Acid," in your number of the 13th inst., I beg to state—1. The parties referred to did not suffer from asphyxia symptoms; and, 2. The time was probably sufficient for the escape of the effluvia, being from about ten o'clock p.m. to seven o'clock next morning. The questions that press on me relative to the case are these—Are turf-coals, burned as described, capable of producing poisonous gases? If so, what are the gases so generated? If not trespassing too much on your much engaged time I will thank you to let me know, and if a private note is more convenient to you, it will answer me quite as well as any other means of replying.—Truly yours,  
A SUBSCRIBER.

### MEDICAL APPOINTMENTS.

ANDERSON, J. G. L.R.C.P. Edin., L.S.A., L.M., has been appointed Resident Obstetric Officer to St. Mary's Hospital, *vice* Thurgar, term of office expired.

CARTER, ALBERT E., L.R.C.S.I., has been appointed Assistant-House-Surgeon to Northern Dispensary, Liverpool.

HAYDEN, J. AUGUSTUS, M.R.C.S.E., L.M., L.S.A., has been appointed Assistant-House-Surgeon to the St. Pancras Workhouse, *vice* Edward Mahoney, M.B., M.R.C.S.E., L.S.A., resigned.

MURIEL, R., M.R.C.S.E., has been appointed a Surgeon in Ordinary to the Ely Dispensary.

RANDALL, JOHN G., M.R.C.S.E. Eng., has been appointed House Surgeon at the Male Lock Hospital, Dean-street, Soho.

SINCLAIR, Dr. G. M., has been appointed a Surgeon in Ordinary to the Ely Dispensary.

SMITH, HENWOOD, M.A., M.B. Oxon., M.R.C.P., has been appointed Physician-Accoucheur to the St. George's and St. James's Dispensary (Mount-street branch).

SMITH, R. AYE, L.K.Q.C.P. (Exam.), L.R.C.S. Edin., has been appointed House Surgeon to the Sunderland Infirmary and Dispensary, *vice* Dr. Dixon resigned.

STERLING, H. H. J., M.R.C.S.E., has been appointed Resident Medical Officer to the Metropolitan Free Hospital, Devonshire-square.

### MEDICAL DIARY OF THE WEEK.

WEDNESDAY, FEB. 20.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE. 8 P.M.

THURSDAY, FEB. 21.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Vibratory Motion, with Special Reference to Sound."

HARVEIAN SOCIETY OF LONDON.—8 P.M. Mr. Victor de Méric, "On Some Complications of Gonorrhoea."—Mr. Teevan: "Cases to Demonstrate the Use of the Urethroscope."

FRIDAY, FEB. 22.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL INSTITUTION.—8 P.M. Mr. M. D. Conway, "On New England."

SATURDAY, FEB. 23.

ROYAL INSTITUTION.—3 P.M. Mr. G. A. Macfarren, "On Harmony."

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

BOWEN.—On January 23, at Quebec, the wife of R. Bowen, Esq., Surgeon, Rifle Brigade, of a daughter.

EVANS.—On February 11, at Cheshunt, Herts, the wife of Nicholl Evans, M.D., of a son.

EWING.—On February 6, at Buttevant, the wife of Surgeon-Major Ewing, 62nd Regiment, of a son.

DAVIS.—On February 4, at Abbey-gardens, St. John's Wood, the wife of W. F. Davis, M.D., Assistant-Surgeon H.M.'s Madras Army, of a son.

FOSTER.—On February 9, at Fortune's Well, Portland, the wife of E. B. Foster, M.R.C.S., R.N., H.M.'s brig *Heret*, of a son.

GRIFFITH.—On February 9, the wife of Dr. S. C. Griffith, of 57, Wimpole-street, Cavendish-square, of a son.

OLIVE.—On January 31, at Northampton, the wife of E. H. Olive, M.R.C.S.E., of a son.

PROTHEROE.—On February 6, at Gosport, the wife of E. Shaw Protheroe, Esq., Surgeon-Major R.A., of a son.

### MARRIAGES.

CHENNELL—ROLPH.—On February 9, at St. Martin's-in-the-Fields, S. P. Chennell, M.D., to Jane Edwards Rolph, eldest daughter of the late R. Rolph, Esq., J.P., of Sandwich, Kent.

GRANT—DUGUID.—On January 31, at Westerton, Huntly, N.B., R. A. P. Grant, Assistant-Surgeon 43rd Light Infantry, to Jeanie, Frances, only daughter of the Rev. W. Duguid, D.D., Glass, Huntly.

HUGHES—EDWARDS.—On February 7, at St. Hilary Church, Denbigh, J. R. Hughes, M.D., of Denbigh, to Margaret Eliza, eldest daughter of the Rev. R. Wynne Edwards, canon of St. Asaph and vicar of Rhuddlan.

STEVENSON—MABERLY.—On February 7, Thomas Stevenson, M.D., M.R.C.P., Angell-park, S., to Agnes, third daughter of George Maberly, Esq., London.

### DEATHS.

GOLDIN.—At the Naval Hospital, Plymouth, W. G. Goldin, M.D., Surgeon R.N., late of H.M.'s Ship "Orlando," aged 46.

ELSDALE.—On the 25th ult., R. Elsdale, M.R.C.S.E., of Moulton, Spalding, Lincolnshire.

MAYER.—On the 3rd inst., J. Mayer, M.D., M.R.C.S.E., of Macclesfield, formerly of Newcastle, Staffordshire, aged 63.

HETLEY.—On the 4th inst., at Norbury Lodge, Norwood, Surrey, the Lady Charlotte Hetley, the wife of Frederic Hetley, M.D., and fifth daughter of the second Earl of Norbury and Baron Norwood.

BRUCE.—On the 7th inst., W. Bruce, M.D., of Kensington-crescent formerly of Madras, aged 75.

FISHER.—On the 9th inst., Dr. A. L. Fisher, of York-place, Portman-square, aged 69.

DAVIES.—On the 11th inst., R. Davies, M.R.C.S.E., of Gray's-inn-road, formerly of Holborn-hill, aged 73.

## THE INFLUENCE OF THE DISCHARGES AND NERVOUS SHOCK ON THE COLLAPSE OF CHOLERA.\*

By JOHN COCKLE, M.D.

PHYSICIAN TO THE ROYAL FREE HOSPITAL.

I AM anxious to bring before the Society, as succinctly as possible, some observations on the influence of the discharges and nervous shock on the collapse of cholera. I do so feeling that the proper discussion of the subject in a Society like the present is best calculated to develop what is theoretically valuable in Pathology—what really serviceable in treatment.

The disease, it is true, sleeps for the moment but, if we look to the history of former epidemics and watch the local rekindlings of the last, there is reason to fear that the cause may be still latent, possibly to awaken to its accustomed activity.

During the pause, therefore, we ought calmly to survey our past doings and if we have been found to cling so fondly to any "idols of the den" as to give our theories too much rein, we shall find wholesome restraint in the greater wisdom and moderation of those around, so that good must accrue both to the individual and to science at large.

Unity of opinion on a subject so intricate and one, still hot with debate, I am well aware, cannot be expected, nevertheless, a very cursory survey of the actual position of the pathology and therapeutics of cholera must convince us that a much wider divergence exists than is compatible with the safety of the community and the intelligence of the profession.

It would seem the veriest platitude formally to affirm that, if the theory were unsound the practice probably would be unsafe yet, viewed in its practical working the proposition cannot be overestimated, since life is the stake we play for.

A divergence of opinion then so manifest does not speak hopefully for our science. Indeed despite the hopes for years indulged, the old question as constantly asked and as variously answered since 1832 still presses on us under the additional light it is fancied that we have for a final reply.—Is cholera the result of a specific poison inhaled into the lung and passed into the blood, working mischief there, yet with a tendency to arrest by a salutary outpouring from the stomach and bowels? Such outpouring being thus secondary and, probably, conservative; or, is this outpouring an essential part of the disease—equally the result of a poison but located in the gastro-intestinal tract and reflecting its violence over the system?—the outpouring, thus, being primary and certainly destructive.

Such is the dilemma to which I specially invite your attention.

Permit me, first, a brief allusion to one, not only of the most controverted but, of the most interesting points in the morbid anatomy of cholera from its bearing upon the progress of the disease viz. the condition of the great organs of circulation and respiration. It is allowed that in the various epidemics, both symptoms and *post-mortem* results somewhat widely differ. Still, after very extended and, I hope, impartial investigation of the subject, to my mind, the mass of evidence in favour of stasis in or, the transit of dark blood, through the lungs, is so overwhelming, that it must be considered as a more or less general fact in the algide stage of cholera. To doubt it, would be to impugn either the good faith or competence of the numerous observers. In earlier times, without any special theory to support, we may not, for one moment, challenge the one, and the simple evidence of educated sense is, surely, a sufficient guarantee for the existence of the other. The

test of the balance has, in some cases, shown, as might be inferred, the congested lung to be heavier than normal. In a few instances, it is stated that the left ventricle was alone distended with black blood. I have, elsewhere, attempted to show that changes in the distribution of the blood may occur *after death* but, that these latter phenomena are not so explained, will be subsequently seen. On the other hand it must be confessed, however we explain the matter, that very many examinations have shown the blood to be arrested at the right heart, and the lungs and left heart, left, comparatively, bloodless. This condition has been particularly adverted to by authorities at home and abroad. At home, by Dr. Parkes whose researches are so often and so deservedly quoted. In his summary, the only point we miss in this portion of morbid anatomy, is the condition of the coronary arteries; such condition must have a significance for, if arrest of blood occurred at the right heart, these vessels would bear to the cardiac structure blood, deficient in quantity, if black blood passed, defective in quality; on either alternative, the normal balance of the heart would be disturbed. Furthermore, the state of these vessels might furnish a key to that congestion of the coronary veins Dr. Parkes so frequently observed and, which, else, would stand out as a bare fact, recorded, but unexplained. If little or no blood entered the left heart, the explanation of such distension of the vein would not always appear upon the surface of the matter, seeing that the blood of the turgid right auricle could not force the coronary valve. If, on the other hand, impure blood of given quantity entered the nutrient arteries of the heart, we might account for the distension of the veins and the dark ecchymoses often surrounding them by the *stasis* induced by such blood in the cardiac capillaries, and veins. Simple *plenium* of the right auricle would not prevent the ingress of the coronary venous blood, since its walls are often flaccid. Apart from this, however, none of the results described are peculiar to cholera, they equally occur in algide fever, yellow fever, serpent and other poisons and, probably, in other diseases also. So that, in epidemics of cholera, if we look at all that *post-mortem* examinations unfold—appearances sometimes slight, sometimes variable, at other times, opposed, and, often, common to other diseases—we must concede that mere morbid anatomy fails to satisfy our wants as to a pathology of cholera.

To proceed to our more immediate subject. The first point for consideration is as to the existing amount of evidence for the presence, in the blood, of some specific poison. I commence with one of the weakest points that could be urged on any ground of opposition to such view, indeed, I state the facts here rather for the purpose of obtaining your opinion than for that of wielding them against the hypothesis in question. I refer to the bursting out of the disease in the midst of perfect health, and will simply take two illustrations from Indian experience. In one case, an officer had been out tiger hunting in the morning and returned to quarters in the highest health and spirits; during breakfast, he was suddenly seized with watery vomiting and purging, and the disease was, almost immediately, confirmed. In the second case, another officer in the very plenitude of health and spirits, went, after breakfast, to bathe with his companions; while in the water, serous vomiting and purging instantaneously set in and collapse speedily followed. Do either of these cases find, in your minds, satisfactory explanation on any theory of a poison in the blood? can you imagine a disorder so produced attaining its meridian of violence suddenly in the midst of vigorous health and elastic spirits or, a discharge to be critical without our having the slightest insight into the necessity for a crisis; and surely to avoid an inconsequence, if we affirm "critical discharge" we ought to have some knowledge of the state related to this predicate, otherwise we oppose a positive term to the vaguest possible correlative. Besides, what could a critical discharge superadd to perfect health? At least, whatever doubts you may entertain, are not the symptoms quite as reconcilable on the supposition of some change originating in the gastro-intestinal tract and called into action by the stimulus of

\* Read before the Medical Society of London, Feb. 11, 1867.

the food in the one case and by the sudden revulsion, in the other, on the mucous membrane?

Next, if cholera poison can, by inhalation, pass into the blood, it ought equally to be capable of exhalation and, thus, of reproduction. A large experience opposes itself to this hypothesis—practitioners, nurses, friends are constantly breathing the very breath of the sufferer, examining the fresh discharges—and when does a clear case of propagation thus occur? That attendants, occasionally, are attacked by cholera is very true, but, comparatively, so rarely, that when an epidemic influence is present we may as fairly assume such attack to be, possibly, a simple coincidence.

I am far from denying the contagiousness of cholera under certain conditions, doubting, only, whether it be through the medium of *recent* excreta.

The blood of cholera patients has, in many cases, been passed into the circulation of healthy persons, from accidental wounds or intentional inoculation, and, never, with any untoward result. The blood, in larger quantities, has been injected into the veins of animals without producing true cholera; ill results have unquestionably followed, but these have been nearly conclusively shewn to be the result of blood *sepsis*, and not choleraic.

Infants, again, have often been suckled by mothers, suffering under confirmed cholera but, in no instance that I am aware of, has the disease been communicated to the child thus exclusively nourished, prior to the actual invasion. A secretion so prone to be influenced by matters in the blood, and to influence the offspring seems, here, to bear no poisoned taint. It must not, however, be forgotten that cholera is rare in infants at the breast, but this fact does not at all explain the immunity, if the blood circulate so subtle a poison as that of cholera.

The recent excretions, just separated from the blood, and which ought, equally, to be most infectious, have been repeatedly tasted and even drunk by man, and injected into the veins, stomach, and bowels of animals, without sensible influence over the health. In fact, the former series of experiments have been repeated so many times upon the human subject without injury, that I attach very little importance to experiments on animals where results are said to have been produced. The researches of Pettenkofer and the latest experiments in Paris, tending strongly to support them, show that the *recent* excreta are innocuous when introduced into the system; some short time must elapse until decomposition furnishes the *materies morbi*.

If we further look at a certain proportion of cases in which sudden relapse occurs, 14 or 16 days after apparent convalescence and nearly always resulting either from error in point of quantity or, quality of food or, the operation of cold and damp we cannot reconcile, with our present knowledge, such relapse with the notion of a poison in the blood. To suppose that such an active agent could, thus, rest dormant, would amount to a virtual denial of its leading attribute, and seems at variance with any theory of elimination.

The researches of Dr. Beale, showing alteration of the intestinal villi, apparently of some duration, do not support the theory of an eliminative poison of the blood nearly as much as that of some agent acting from the intestinal tract.

Next, with regard to the theory of elimination. The term, though in current use, is not at all times very strictly defined as to its extent of application. We, surely, ought severely to distinguish between simple and critical elimination; they clearly mean very different things. With reference to the pathology of cholera especially is it more than ever necessary to define our terms. We know that certain remedial agents may exhibit special affinities for certain organs; thus, juniper may tend to the kidneys, squills to the mucous membrane of the lungs, elaterium to the stomach and bowels, mercury to the salivary glands and so forth. These agents may, though the fact is not proved, eliminate themselves through these several tracts with the secretion they increase, and, even carry with them injurious matters from the blood; though the latter result

would, probably, in a logical sense, be an accident of their action. Few such agents have any special power to select and carry off an actual poison from the blood; they eliminate, and, in the current, sweep away morbid matters. The agent employed is obedient to certain laws. From a multiplied experience we anticipate the effect and can control it often at our will. Should the agents act with undue violence, they require restraint. But we should hardly venture to apply the term *critical* to such discharges. A critical elimination bears the impress of something like intelligent design on the part of Nature, and, on her part alone. We can rarely predicate either the time, manner, or even site of its occurrence—now, by hæmorrhage—now, by abscess—at one time, by a sweat, at another time, by a diarrhœa, sedimentary discharge from the kidneys, or, by long and restorative sleep. Whichever of the selected modes, they all possess in common the characteristic of affording speedy and direct relief to the maladies in which they occur, and this generally happens during the stage of reaction. This is precisely what we should expect from the extrusion of a poison which had vitiated the composition of the blood and aroused a reactive energy of the system and should hesitate to apply the term *critical* where no corresponding relief occurred. This is the rule. But, even in cases where Nature oversteps her mark and such discharges exceed the limits of relief, no sound practitioner ever hesitates in an attempt to moderate their violence.

In *confirmed* cholera, all is reversed. Gastro-intestinal discharge is the constant, overt, *initial* phenomenon; it occurs under depression, and progresses and culminates under exhaustion and collapse. Even assuming, for a moment, cholera to result from a poison in the blood, if we question ourselves, how little do we know of such agents! Absolutely nothing as to their essence, and but little more as to their proximate action. We are only cognisant of the wreck they occasion.

But, if we were, provisionally, to assume that a volatile matter entered the blood in some definite quantity or, to form with some element therein, a definite concrete (the hypothetical cholera-cathartine) the nature of the disease would be intelligible enough, we might reasonably infer that such a compound from its drastic essence, might eliminate itself and bring its own cure or, be restrained by treatment.

So conceived, a theory of simple elimination would be rational and in harmony with what we know of drastics acting by absorption, and, in the category of these, it might be included.

But, if the poison be regarded as zymotic, fermenting the total mass of blood then, I apprehend, such an action would furnish the best argument for our assuming that cholera poison contributes to a fatal issue by drain of nearly all the available serum of the body, and, *a fortiori* a sufficient reason for regarding the discharge as non-critical and for checking it if we possessed the power.

In an avowed ignorance, then, of the exact operation of this blood poison, it is open to all to speculate and guess, for guessers are somewhat like archers, now and then, an outsider gets a gold centre. I would make one trial which you will accept *quantum valeat*. If we are to assume that cholera really be an inhaled poison, and to believe, as I fancy we must, that it is not directly infectious, I would ask whether some volatile element inhaled, might not form with another element of the blood a definite concrete—a dangerously depressant emeto-cathartic, which thus acts only as a *poison to the individual*. When the excretions are passed, after two or three days, decomposition occurs the volatile agent is again set free, and either held in solution, or volatilizes and passes away to react upon some other predisposed organism.

Such, is the doctrine of a poison in the blood, and, of the contingent effort for its removal by discharges from the stomach and bowels; a doctrine most suggestive, and possibly, sound, though, to some minds, wanting in the full evidence to make it binding on belief. We may, therefore, very properly seek to obtain either a reversal of the sequence or, at least, a suspension of opinion, should equal

or better evidence be adduced in favour of a different view.

We might submit that the internal or external drain and co-etaneous shock upon the nervous system is the essential—is the actual disease without which, it would not be cholera; and, that true algide phenomena do not occur either before or, without, the drain or, whatever else, we term that matter either fluid, or semi-solid which fills the stomach and bowels, consisting of the spoiled elements of the blood. In nearly every language cholera implies a kind of colic, flux, or draining from the bowels with rapid loss of power. This is the one great result which remains permanent under all the varying conditions that post-mortem examination reveals.

The history of the various epidemics clearly shows that the disease may be ushered in by *prodromata* or, that these may be entirely wanting.

Where such exist, as, for example, lassitude, vertigo, singing in the ears, disturbed vision, pallor, syncopal tendency, anorexia, thoracic, or abdominal uneasiness; they are quite explicable on the supposition of some local disturbance of the gastro-intestinal tract—irradiations from the great epigastric centre and intestinal plexuses; indeed, several or nearly all of these symptoms attend, to some extent, the commonest disturbance of this tract, so that no necessity need exist to push back this semeiology to prior changes in the blood. We must not forget one first great law of philosophy "*entia non multiplicanda sunt, præter necessitatem.*"

In other cases, diarrhœa, variable in duration at first, without compromise of the general health, and nowise distinguishable from a common looseness save by its endowment, potentially, to spread the disease, precedes and, in an immense majority of cases, gradually or suddenly merges into confirmed cholera. On this point, the opinions of the most experienced men, of all countries, are almost unanimous. If this diarrhœa is checked which is generally practicable in the earliest stage, health is, at once, re-established. This unquestionable result again, strongly pleads in favour of the local origin of the flux, and stands in striking antithesis to the doctrine of a poison in the blood requiring elimination by such an outlet, and which being hemmed in, ought, *ex hypothesi*, to be followed by alarming internal disorder, since Nature never permits us to arrest a truly critical discharge with impunity.

When the disease suddenly explodes as confirmed cholera, as it does at times, and in the midst of seeming health, the site again is local, whatever the cause may be. A double change almost simultaneously occurs—shock upon the nervous ganglia (in some very rare cases so intense, as rapidly to arrest the higher functions of respiration and circulation, and kill before more marked phenomena are seen;) and a sudden rush of serum of the blood through the walls of the stomach and bowels;—a rush, at times, so enormous that as Moreau de Jonnès describes "it seems, at times, greater than the entire mass of fluids in the body" to quote another great author, Cruveilhier, "this enormous abstraction of the serum of the blood of the cholera patient in a few hours, nay, even in a few instants, explains the symptoms of the malady much better than any alterations of structure."

This sudden and immense drain of blood elements nay, in those rapidly fatal cases just referred to, simply fill, to distention, the stomach and bowels, without outward issue, thus resembling internal hæmorrhage though hidden from our sight, still, lost to the circulation, revealing itself to our sense by palpation and percussion, the features expressing the loss the circulation has sustained.

Here, you will pardon me a short digression with reference to the subject of transudation through the bowels, which, at has been of late, too much the fashion, if not to ignore, at least, to under-estimate this influence in the causation of collapse. According to my experience, a graver oversight could not occur in the pathology of cholera.

Those pathologists, of course, who look upon collapse under the light of another causation, and regard such condition either as resulting from the special action of a

poison on given vessels or, from the shock communicated to the nervous centres from an inflamed condition of the bowels, would regard the discharges as of subordinate importance. With every respect for those who hold such views, and held, possibly, on a securer tenure than my own, I still must say that, to disregard the influence of discharge appears to me, a backward step, in every sense, in the pathology of cholera. Such is its significance that I think it fair to call your attention to some facts connected with the influence of intestinal discharge upon the circulation in its least complicating shape, we may, then perhaps, better estimate its influence on cholera.

Many have read the narrative of Morgagni. This great physician, once travelling post, to visit a patient, was seized with sudden looseness of the bowels and passed, successively, in twelve hours, sixteen pints of serous fluid. In this brief interval, he had become so emaciated as if he had suffered from some long and wasting malady, and his weakness was extreme for several days.

Cruveilhier states, that when at Limoges in 1818, during a very hot summer, he was called to a woman 40 years of age whose features were so profoundly changed, her face so sunken and discoloured, that he supposed the case one of abdominal disease in the last stage. Have you been ill long? "No!" was the reply in a hoarse voice. "This morning I left my house on business in perfect health. On my return, I was seized with a looseness and passed, rapidly, an enormous quantity of water." So that in a few instants this woman was perfectly prostrate.

The same Physician, again, states. "I was sent for at Paris in March 1849 to a young girl from Auvergne who retired to rest in her usual health, and whom I found dying at 7 A.M. Upon entering her small chamber, I saw the floor inundated with water. It was cholera discharge passed, involuntarily, during the night and which had soaked through the mattress. She died, a few moments, after my arrival." To avoid being tedious, I will only cite one more example, quoted by Trousseau and Pidoux, from Barbier's work on *Materia Medica*, and which he personally observed—A woman, in one of the faubourgs of Amiens, took a purging medicine from a herbalist, it caused such excessive discharges by vomiting and purging, that rapid exhaustion ensued. Being conveyed to the Hotel Dieu, the following morning, the tip of the nose, the ears, and cheeks were of a very dark violet colour as, also, the hands and feet. Gangrene rapidly followed, and she lost one of her feet, and some phalanges of the toes of the other.

Now, we must remember, with one exception, these were the results of simple drain in healthy constitutions, and had they lasted, would not the truest algide collapse speedily have followed? They closely resembled, in their effect upon the system, those of cholera, stopping short of collapse. The occurrence of gangrene has been several times observed in cholera, and doubtless from the same cause.

(To be continued.)

## REMARKS

ON

### AFRICAN, WEST INDIAN, AND OTHER FEVERS AND DISEASES.

By ALEXANDER LANE, M.D., Surgeon Royal Navy.

HAVING served for a considerable period on the West Coast of Africa, and in the West Indies, as well as in the East Indies, Southern Pacific, Mediterranean, and other parts of the world, I had a very good opportunity of seeing and treating this disease, known on the coast of Africa as the Bullam, and in the West Indies and other parts as *yellow fever*. My first acquaintance with both—if they are not both one and the same disease, which I think I will satisfactorily prove, was on board H.M. Ship *Iphigenia*, in 1822.

We arrived on the West Coast of Africa in the latter end of January, in the cool season of the year—if any portion of the year can be called cold, or cool, upon that Torrid Continent, and we left it on the 26th of June following,

when we sailed for the West Indies, which we also left on the 5th of September following for England, via Sandy Hook, New York. When the Americans found that we had the "yellow fever" on board, they put us into the strictest quarantine, though the weather was stormy and cold; they anchored a vessel near us, from our Consul, laden with live stock, fruit and vegetables; the crew left the vessel, and we had to haul her alongside, take our supply on board, and anchor her again at a distance; such was the dread of this disease amongst the Americans, but it only went to show how very inconsistent man is in almost every relation of life, for whilst they were so very particular with us, they had no land quarantine between New York and New Orleans and other places, when the yellow fever existed. We had lain four days in the Rio Gambia, and six in the Rio Noonis, before we went down to Sierra Leone, where we arrived of the 17th of February; the months of March and April were pretty healthy, although we had twenty-three cases of diarrhoea from eating too much fruit. We had a solitary case of "fever" in March; we had visited all the usual stations down the coast, had fought a desperate boat action in the river Bonny, had been to St. Thomas' on the equator, and returned to Sierra Leone, before this disease made its appearance, which was about the middle of May; and from this period until we had arrived in the cold northern regions it could not be said that we were free from the malady. From the coast of Africa we went direct to the West Indies, and remained twelve days at Port Royal, Jamaica, from whence we went to the Havana, where we remained one and twenty days; we had ninety-two cases on the coast of Africa, and one hundred and thirteen at the Havana. I had thus an opportunity of examining carefully and minutely into the nature and origin of this disease on both stations, and of remarking any difference or peculiarity, if such existed. In all cases which came under my observation the attack was precisely the same; each question had to be particular and pointed, and a direct answer required from each patient; at first there was an uncomfortable feeling, and nausea with restlessness, this was generally speaking of short duration, it was quickly followed by rigors or cold chills; the shaking and shivering in those paroxysms were very violent, and so great was the sensation of cold and the chattering of the teeth that no coverings whatever could produce any degree of warmth until the paroxysm had subsided; then succeeded a violent reaction. The first symptom was the quick pulse, then headache and heat of skin, thirst, dry tongue, suffusion of eyes, pain all over, and loins particularly, general languor and listlessness. Sometimes the intense heat of skin (when you placed your hand upon it) would produce over your whole system a pricking sensation, as if you had been stung by nettles, and so lasting and so disagreeable that eau de cologne could not remove it. I have felt it for two hours. Those were the most prominent symptoms on both stations, and this is the state in which you find a patient labouring under what is called "Bullam, or Yellow Fever." The symptoms may be very violent, the headache intense, the thirst urgent, but *those symptoms are symptoms only*; they had a cause, and that cause produced them, and they are clubbed together and called "Fever." They are supposed to form this so-called disease; thus, when a physician is called in, he endeavours to remove the symptoms without considering the cause which brought them into existence, and keeps them in activity until either the virus loses its power over the constitution or the accidental administration of some medicines to neutralize the poison. Otherwise death must ensue. If the patient gets worse the symptoms increase in violence, accompanied with vomiting, abdominal pain on pressure, high-coloured urine, furred tongue, flagging pulse, and a tendency to delirium; skin becomes clammy, with sometimes a yellowish tinge of body, of the eyes particularly, hicough and vomiting of a dark fluid, petechiæ or purple spots, then death finishes the scene.

I once had a patient in this latter state, and had given the case up as hopeless, when a sudden thought struck me

to venture an experiment. I sent for a bottle of pale brandy, and I succeeded in pouring down his throat two tumblersfull in its undiluted state. The poor man said something, but I could not make out what he said; however, down fell his head, the vomiting ceased, and he fell asleep, from which he did not awake for 25 hours. Nothing could awake him, but the pulse was present, though very small and weak, but not wiry, rather soft and compressible. The skin felt more natural when he awoke. I was standing by his hammock at the time, and his first words were, "I'm very hungry," though they were very feebly enunciated. I gave him some preserved soup, warmed with a little wine, which he seemed to relish much. He then fell asleep again, and slowly recovered under a generous stimulating diet.

One morning I bled an athletic Irishman largely—say thirty-six ounces. I tied up his arm, and laid him down on deck until his hammock was ready. In the meantime, whilst I was bleeding others, the bandage slipped off his arm, and he bled so profusely that we had difficulty in restoring him. Next morning he was convalescent. This accident led the surgeon to believe that bleeding repeatedly, *ad deliquium*, would be the best mode, and adopted it accordingly; but, in each instance, it did not produce the desired effect, and therefore it was given up. The nausea or vomiting and abdominal pain arrested my attention. Were they merely symptoms of the disease called fever, or did they point to a more dangerous action going on within the abdomen? Several opportunities were offered me at Sierra Leone, and I gladly seized them, notwithstanding the heat and rapid decomposition, nor did I care much for the supposed contagion. I wanted to see the result of the "fever," and judge for myself. I therefore had several post-mortem examinations, which threw much light on the subject, and showed me in what manner the disease proved fatal.

In all those cases I found no disease in the lungs or heart. The abdominal viscera—that is to say, the intestinal tube and its peritoneal connections were the only parts which showed the result of action—inflammatory action—in some cases most violent and extensive, glueing them, as it were, together in a mass, inseparable unless by violence. In one case there was slight cerebral congestion; but, as far as these cases went to show, they proved that this disease called "fever" was nothing more or less than inflammation of the bowels, the result of a specific poison. As to the cause, I could only refer it to some powerful atmospheric poison, a poison *sui generis*—a poison which could strike down and kill the most healthy man. A specific poison, absorbed through the lungs and thrown directly into the circulation, directs its baneful attack upon these parts of the human system at once: this is called "Bullam," or "Yellow Fever." When the liver or any other organ becomes implicated, then it becomes complicated, yet all go under the same name though marked sufficiently.

This, then, is the plain matter of fact, freed from all clap-trap and nonsense, and medical jargon besides. All those symptoms are symptoms only—symptoms indicating injurious action in the arterial system, increasing in violence as their violence indicate, directed to some portion, if not the whole, of the alimentary canal, and of a very peculiar character. It must, therefore, be evident that those symptoms are not a disease in themselves, but merely point out to the physician the work of destruction which is going on.

The power or influence of mercury in certain inflammatory diseases is too well known to require any additional support; therefore, I thought that if the system could be speedily placed under its influence by large doses of calomel and camphorated mercurial ointment the disease would be overcome, or, in other words, that mercury was a specific against this poison. This has been proved a fact, as we did not lose a patient whose system could be, or could have been, placed under its influence; but it was not every patient whose system we could mercurialize: hence the failures. My own life was saved and my brothers lost, upon this very principle. Observing that the mercurial

system could not be depended upon in all cases, I began to think that there might be some other medicines which would act more specifically upon this poison, which would neutralize it in the blood, and cause, perhaps, less constitutional derangement.

I could not imagine that a symptom was a disease; for instance, a quick pulse, a hot skin, or a headache; what they are not singly, they cannot be combined. Fever in itself is merely heat of skin; in any disease when there is no heat of skin present there is no fever. Thus, then, when the heat of skin is above the natural standard fever is present, and the different symptoms which present themselves beside this, give it its particular name. When the symptoms are mild, it is called slow, or simple continued fever; when they become worse, it is called active inflammatory fever; when they become more violent it is called typhus, or typhoid, or yellow, for a symptom with some will make a difference in name and treatment. A circumstance occurred which caused me some reflection. It was supposed that as soon as we got into cold weather the disease would at once disappear; in place of that, in the month of October, on our voyage from Sandy Hook to England, we had several new cases; but although they all had the usual symptoms, they were much less violent, and yielded easily to mercurial treatment. On strictly questioning these men, I found out that they had all been unwell the day we left the Havana, and had been loitering about hardly able to do any work, and that they would have applied earlier, only they knew that their "rum" would be stopped. This was quite satisfactory, and confirmed me in the belief that *there will be no such disease where the means of its production do not exist, and that it is not personally communicable.*

On our arrival at Spithead we communicated with the shore, and no evil results followed, though the next day we had to remove to the quarantine ground. In four days after, we were at Chatham, where, in less than an hour, the ship was so completely filled with people that you could hardly make your way through them, yet none of the visitors suffered from their coming on board and getting into close contact with those labouring under the disease, though they were all in a state of convalescence. Moreover, I am certain that the first night we had on board three women for every man in the ship, which converted the lower deck, for a time, into a perfect pandemonium.

Now, in this case, we had had this disease on board in its most malignant form; we lost eighteen officers and men; came home with a number of sick and convalescent on board; got the very stronghold of the malady—the lower deck—filled promiscuously with people, many of whom remained on board and slept below, and yet no evil consequences follow. I should think that this was pretty strong presumptive proof that the malady was neither infectious or contagious, and that it requires the presence of the original poison to produce the disease. The next place I met with this disease was in the Mediterranean, in H.M. brig *Sparrowhawk*, in 1824 and 1825. Fifty-eight cases came under my observation. I had, besides, the good fortune to see several post-mortem examinations (at Naples) of those who had died from fever, and although I did not see any of them during their illness, on close examination I could detect, and without the aid of a microscope, the result of inflammatory action in various portions of the intestinal tube; there was great emaciation in all, and therefore the blood must have been very poor, and the action of the heart was not sufficient to drive the blood with such force as in a stout plethoric Englishman, consequently the results were less conspicuous, yet sufficiently so as a proof of its existence. The mode of treatment I could not ascertain; however, the mouth presented no appearance of their having been placed under the influence of mercury.

In all those cases which came under my own immediate observation I could see no material difference, between them and those of Africa and the West Indies, except that in some cases the symptoms were not so very violent, depending, I presume, on the virulence of the poison—these were rigors, heat of skin, quickness of pulse, thirst, headache,

&c.; yet, generally speaking, the disease appeared in a milder form, and was more easily subdued, because I think that, though the symptoms were evidently of the same description, there was some peculiarity in the nature of the poison; the cold paroxysm was not so violent, and although there was some disposition to the yellow effusion, it was much less prominent, which I attributed to the fact that, none of them assumed a dangerous or fatal character—the most severe was in the person of an officer, and the yellow tinge in the eye was quite perceptible. This case was designated as "bilious remittent fever," and I fancy there was, or had been, an absorption of bilious fluid.

In 1827, 1828, and 1829, I was in the West Indies, and during all that period I only lost one patient from this complaint, but, it was complicated with other diseases, and delay in making early application, so that there was little or no fair play for either doctor or patient.

In 1830 I was on the West Coast of Africa, and had again some post-mortem examinations which all tended to one result. Here I lost one patient from causes similar to the former. Where there is a combination of disease and a dissimilarity in treatment, the chances against hope are far too numerous, and, generally speaking, such events must naturally be expected. In 1831 I was in the West Indies, where I remained until April 1834, during which time three hundred and ninety cases came under my observation. Out of this number only one died, who had, besides, diseased liver and lungs. Some of those cases I was obliged to send to hospital, because I had not sufficient room on board, and I had no assistant; therefore, the labour became too much for me, but, on the return of the convalescents, there was not one who had not been placed under the influence of mercury, and I had to place all on the convalescent list from ptyalism. This is only an additional proof that mercury is an antidote against this poison in all cases where the system can be placed under its influence.

In 1839, I was in the East Indies and the Southern Pacific. Eighty-seven cases without loss came under my observation, differing in no essential from those of Africa or the West Indies; there were the rigors, quick pulse, hot skin, headache, thirst, &c., &c. I could not observe any difference, and I not only believed them to be *one and the same disease, but treated them as such*, and the result proved that I was not wrong in my prognostication. However, I did not place my sole reliance upon mercury; there were other medicines which I thought would neutralize the poison as well, and I had occasion to observe that, where the mercury did not act, the patient had as good, if not a better, recovery under their influence than when it acted. There was no foetus of breath, loosening of teeth, &c. This latter treatment was more successful than the mercurial, and the patient much sooner and with greater certainty placed under its influence, and also with much less detriment to the constitution generally. There is a vast amount of importance in early application, as the case becomes almost hopeless if medicine cannot affect the system; those fatal symptoms soon set in which get the name of typhoid, it being impossible to arrest the effects of the poison.

With regard to the yellowness of the skin, it must arise from one or both of these causes—an absorption of bile, or some peculiarity in the poison; but I feel disposed to attribute it to the former, though chemical analysis, I believe, seems to doubt it. I now felt satisfied that all those diseases called "fever" arose from a similar poison, and were only to be found where the means for its production were in abundance, and which *would be found in Northern Europe if a tropical heat could remain sufficiently long to produce it*, but that which is produced, its "Prototype," is much milder in character, though not the less fatal, because, I fancy the mode of treatment is not sufficiently active; it is sometimes slow in its development, is very insidious in its progress, and throws the physician off his guard. The virus of small-pox (and this disease, as well as many others, is accompanied by fever or heat of skin) will produce no other dis-

case; and *this is the case with every disease, each possessing its own peculiar virus, or poison, and "virus" everything must be, which is prejudicial to the natural health of the body; and where do they exist if they do not exist in some peculiarity of the atmosphere? They must have generating causes, unknown to us, the blood is first poisoned, and the heart being stimulated by its unusual presence increases its action and drives it through the whole system rapidly. This disease called "fever" is subdivided into "stages," according either to its duration or peculiar appearance; all those symptoms will.*

(To be continued.)

### A CASE OF CHOLERA TREATED BY SALINE ALCOHOLIC INJECTION INTO THE VEINS; WITH OBSERVATIONS.

By L. STROMEYER LITTLE, B.A.,

ASSISTANT-SURGEON TO THE LONDON HOSPITAL.

EXTREME COLLAPSE; INJECTION; IMPROVEMENT; RELAPSE; REINJECTION; PREMATURE LABOUR; PYÆMIA; RECOVERY.\*

K. S., a well-nourished, strumous-looking girl of seventeen, pregnant rather more than seven months, was admitted into the London Hospital early in the morning of October 3rd, 1866. She had gone to bed quite well, and was seized at two A.M. with purging and vomiting of a rice-water-like fluid. She had had no premonitory diarrhœa.

The report when admitted was:—"Aspect choleraic; eyes sunken; lips livid; pulse scarcely perceptible; she vomits almost constantly, and has copious frequent rice-water stools; cries out piteously with cramps in her legs and belly; complains of thirst; drinks unlimited quantities of cold fluids, and immediately rejects them."

At one P.M. Worse; quite pulseless. It was therefore decided to inject saline alcoholic fluid into the veins, the more so as the purging and vomiting have been very profuse all the morning.

At two P.M.—that is, twelve hours after the commencement of the attack, the operation was performed. At that time the patient was pulseless and voiceless, her respiration forty-five a minute, the temperature in the axilla 93°; the lividity was extreme, and the cramps very severe.

Seventy ounces of the usual alcoholic saline fluid were introduced by gravity into the circulation. Some difficulty was experienced in the operation. The median basilic was opened at the bend of the elbow in the usual way, and the fluid at first flowed very well, but after some few ounces had entered the flow became very slow. As the case required the injection of a large quantity of fluid, the corresponding vein on the opposite side was opened, and the operation continued there. Still the fluid ran in but slowly. There was great immediate benefit; the pulse returned at 100 of fair strength; the respirations fell to forty a minute; voice and red colour of the lips returned; the cramps ceased to trouble her, and she expressed herself as much better. Half an hour after the injection she had a slight rigor; the temperature in the axilla rose to 96, and profuse perspiration came on. The cramps in the limbs had altogether ceased, but she still complained of pains in the belly (probably labour pains).

During the next four hours she got again weaker, and at six P.M. was apparently in articulo mortis; her respiration 60 *in a minute*; pulseless; temperature in the axilla 94. She seemed to suffer much from cramps in the stomach, but her voice and consciousness were gone. The attempt was now made to introduce some more fluid into the circulation, but unsuccessfully in both arms. Recourse was then had to the saphena vein—at first near the knee, afterwards at the ankle; and 120 ounces of fluid were introduced in three quarters of an hour with immediate and lasting benefit. The pulse returned with moderate force at 110, and the breathing had fallen to 42 a minute by the

time the injection was finished. The voice and colour became natural. She had no rigor after the operation, nor any more vomiting; no cramps in the limbs. Her temperature rose to 96 in the axilla; she took beef-tea, and brandy and egg-mixture, and retained it. As the labour pains continued, she was placed under the influence of chloroform, which was continued nearly the whole night. The next day the patient was much better in every respect; she was able to take nourishment; there was no reactionary fever. For further notes of this case I am indebted to Dr. W. B. Woodman. On the 6th, that is three days after the attack of cholera and the injection, premature delivery took place; the pains were most severe. The child was a seven months fœtus, and was born dead. Three days later an eruption appeared on the injected arms, not at first about the wounds, but mostly on the hands, gradually spreading up the forearm. It much resembled choleraic roseola in colour, but was nowhere discrete. After ten days the eruption was like erysipelas, getting dusky, having a tendency to vesication, accompanied with superficial œdema. The whole of both arms and part of the chest were involved in this condition, which was associated with rigors, and was followed almost immediately by pyæmic deposits in both elbow and the right shoulder joints, pulmonary engorgement, and typhoid symptoms. She continued in an extremely low condition for three months, with profuse discharge from numerous abscesses; great dyspnoea and fever. She took chop, eggs, wine, and brandy in large quantities; but every two or three weeks was again prostrated by rigors, in rapid succession. In the middle of January she became convalescent; the abscesses were everywhere healed up, but the movements of the affected joints somewhat impaired.

This case, the last under my care, is also the most remarkable, as the attack of cholera was exceedingly severe and was complicated with pregnancy, premature labour, and pyæmia. The difficulty attending the operation shows that the patient was *in extremis*, that blood clotting had already taken place in some of the largest veins, the respiration being at the rate of 60 a minute, a frequency unprecedented in my experience, and a proof of the severity of the case. The fluid as it would not enter the veins of the arm was introduced by those of the leg. In two earlier cases on attempting the injection into the arm only a few ounces entered, and distended the superficial veins of the limb without passing on to the heart. In these cases after death, the axillary and the larger veins near the heart were found occluded with clots, which prevented any fluid passing. It is reasonable to presume that a similar condition, though perhaps in a less degree, existed in this case, and retarded the first operation. When the second operation was attempted, the superficial veins of the arms were found to be entirely plugged, partly from the stagnation which had taken place previous to the first operation, and partly from the veins having been opened and the arm subsequently bound up to prevent bleeding, the patient being much restored after the operation. In this way we can account for the fact that the injection succeeded in the veins of the leg, when unsuccessful in those of the arm. Another cause of the earlier clotting in the arms may be their more incessant exposure to cold than the legs.

In cases where, with the force of gravity alone, the injection is slow or impossible, fluid might be forced in with a syringe, but probably with injurious, or, at any rate, without corresponding beneficial effects. It is preferable to attempt the operation at a vein in the leg, rather than inject fluid by means of great force into the veins of the arm. The use of gravity as a power offers so many advantages, by securing an easily-regulated continuous flow of fluid at a uniform rate and temperature, leaving the operator free to attend to the symptoms of the patient.

Few cases of such intense collapse as the preceding recover, and no case, to my knowledge, is on record, complicated with premature parturition, which has recovered under any of the usual modes of treatment. A third complication, also likely to have proved fatal, was pyæmia. The symptoms of this disease commenced a fortnight after

\* Mentioned as Case 20 in the table published in this journal, page 590, Vol. ii., 1866.

the injection. At this time the wounds at the right knee and left ankle were healed; those at the elbows, which were much larger and where the tissues had been much pulled about and disturbed, were not healed, but appeared healthy, and there was no swelling or sign of inflammation in the arms. The rash then made its appearance, accompanied with fever, and followed by rigors, and then by the pyæmic deposits in the joints. From the great difficulty of breathing and the expectoration present during the pyæmic stage, it is possible that similar deposits existed in the lungs. Still the case resembled more one of pure pyæmia than one of direct infection from the suppuration of clots in the veins. If such a breaking down of clots took place, then the state of the veins before the operation is quite sufficient cause to account for it, and the clots cannot be ascribed to the operation. Pyæmia did not occur in any case of cholera treated by injection by Dr. Little in 1832 or 1848, nor in any other of my cases. Nor was it observed in any of the cases of venous injection for other diseases or for experiment recorded in the full report just concluded in this journal. At the time this patient was attacked with pyæmia, I had a number of operation cases in the hospital, and none suffered from this disease, nor was it then present in the wards. Parturition taking place during or consequent on an attack of acute disease, such as cholera, severe scarlet fever, or typhus, nearly always proves fatal to the patient, and probably the power of repair then in the system is so small in amount that, where death does not take place, some local death and degeneration in the uterine tissues does take place, and becomes a cause of purulent infection.

It is very probable that parturition, occurring coincidentally with such an enfeebled state of the system, was the cause of the pyæmia in this case.

Recovery under such circumstances proves that the introduction of a large quantity of fluid into the circulation—in this instance, of nearly ten pints—after rousing the patient from collapse, does not lessen his power of repair, nor leave him in a worse condition for the success of the future efforts of nature. In fact, when the introduction of the fluid produces the usual revival of the patient, the fluid remains only a short time in the circulation, and is quickly removed, chiefly by the bowels, the stomach, and the skin. The very revival gives power for the excretion of the injection, hence the necessity for repeating the operation. One man, who nearly six months ago received a gallon and a half of fluid into his veins, tells me that, in consequence, he has had better health than ever before in his life. Although we cannot draw the conclusion this poor man does, it is clear that he is none the worse for the treatment he underwent. In conclusion, all experience demonstrates the necessity for repeated injections, and this fact I beg to impress on any one adopting the treatment of cholera by the introduction of fluids into the veins.

## CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REMARKS ON CHLOROSIS AND HÆMORRHAGE.

(Continued from page 164.)

CHLOROSIS and anæmia, as we have said, predispose to effusions into serous cavities. This may take place in the cavities of the brain. A boy five years of age had been reduced to a state of anæmia by long-continued, wasting fever, and was anasarcaous in the lower extremities. Whilst in this state, though apparently improving in

general health, he became gradually, and at length profoundly, comatose. It was ascertained too, on examination, that there was complete hemiplegia of the left side. He was treated by blisters and mercurial inunction; gradually the coma and paralysis disappeared; as these symptoms subsided so likewise did the anasarca of the lower extremities; and the child, though still pallid and delicate, is now daily improving in health and strength, and exhibits no remaining sign of cerebral disease or dropsical effusion.

Miss B., eighteen years of age, having for several weeks manifested all the essential symptoms of genuine chlorosis, was seized with pain, neither severe nor of long continuation, in the left side, over the cardiac region. She soon became so breathless and weak that I was hastily summoned to see her. I found her scarcely able to breathe, pulseless, and to an extreme degree restless and agitated. The heart was displaced, its hurried and irregular impulses being perceptible only on the right of the median line; and the whole of the left side of the thorax was perfectly dull on percussion and destitute of respiratory murmur. The respiration of the right lung was loudly puerile. Copious vesications were rapidly produced by the free and extended application of acetum lyttæ; after which blisters were laid on the skin; sinapisms were placed on the feet and calves of the legs; and carbonate of ammonia with spirit of nitrous æther given internally. By these means some mitigation of the urgently suffocative symptoms was speedily effected. It had been my determination, had the patient not been quickly relieved, to have had the operation of paracentesis at once performed. Two hours, however, had not elapsed before a marked abatement of the suffocation rendered such a step, at the moment, unnecessary. Mercury was then rubbed in largely, and also given internally; digitalis in infusion was likewise taken. The combined action of mercury and digitalis was most remarkable and gratifying; after an interval of some hours the kidneys began to secrete, and so abundant was the diuresis, that the rapidity of the absorption was only equalled by the suddenness of the serous deposition. By degrees the expansion of the compressed lung became more and more evident, in the restoration and extension of the respiratory murmur, and the gradual replacement of the heart, affording decisive evidence of the favourable progress of absorption. At the end of the third day from my first visit, the heart had nearly returned to its normal position; and the lung, throughout the greater part of the left side of the thorax, had audibly resumed its function. The restoration to health was ultimately complete. In this case it was the sudden change in the condition of the organs—the rapid compression of the lung and displacement of the heart—which gave rise to the suffocative sensations and the imminent danger. Had these changes occurred more slowly, the system would have been gradually accommodated to them, and the immediate danger would have been less pressing. Cases of this kind may arise in which nothing but an early recourse to paracentesis can save the patient's life. This young lady exhibited every sign of constitutional struma.

It may be well here to observe that mercury in this disease must be administered with extreme circumspection. I remember having seen, several years ago, in consultation, a young lady about eighteen years of age, who had been for months previously in the chlorotic state, and who had become universally anasarcaous. She was deadly pale and cold, no artificial appliances availed to maintain warmth in the extremities; the pulse was rapid and very feeble; there was, however, no discoverable evidence of organic lesion. She had been treated before I saw her with calomel in full doses, the result of which was sloughing of the gums and a large sloughing perforation of one cheek. She fell a victim to mercury administered with too unsparing a hand to one long labouring under chlorosis.

I have seen several cases of pleuritic effusion after long-continued fever, where the blood was reduced, apparently at least, to the abnormal state characteristic of chlorosis. I say apparently, because, not having had an opportunity of examining the blood after a long fever, or after profuse

hæmorrhage, I cannot venture to affirm their absolute identity. The similarity, at least, between the two states, is very striking.

I shall give briefly the following case, as an example of the form of pleuritic effusion I have met with in several instances after a tedious fever. A young college student, convalescent after a protracted fever, was observed to alter in his looks, not to improve as he had done, and to breathe more quickly. Not having seen him for several days, I was requested to visit him. I found him in a semi-erect position, inclined towards the left side; he had not experienced any painful sensation, but he felt more languid and weak than he had done for many days since the subsidence of the fever, and both his breathing and pulse were exceedingly rapid. He enjoyed little sleep, and that little was disturbed and uneasy. On examining the chest it was found to be dull on percussion over the left side, throughout its whole extent, and the respiratory murmur was inaudible. The heart was displaced: its impulse being inaudible, with visible motion of the integuments, three inches to the right of the median line. The left side of the thorax to the eye appeared much dilated, though but a small difference was detected by direct measurement; and the slightest exertion increased excessively the already existing dyspnoea. The effusion was, I presume, in this case, serous; it yielded gradually to mercurial inunction, and frequently repeated blisters. Other cases of effusion into either side of the thorax after fever, and several such after severe influenza, have fallen under my observation. In all these cases, long continued febrile action had reduced the frame and impoverished the blood; and it is exactly under such circumstances that a slight inflammation of the pleura is followed by copious serous exudation. These are cases in which, at a certain stage or period of the effusion, the tincture of the muriate of iron may be given with manifest advantage. Profuse, long-continued, and often-repeated uterine hæmorrhage also favours serous effusions. Albuminuria likewise produces pallor, attenuated blood, and tendency to serous effusion. In fact, any disease which deprives the blood of its due proportion of red corpuscles, may induce a state of anæmia, and predispose to effusions of serum.

Malignant diseases and tumours, either with or without hæmorrhage, also produce a perfectly anæmic state, and give rise to anasarca. The condition of the blood in some (particularly the hæmorrhagic) cases of anæmia, appears to resemble, perhaps to be identical with, that of the blood in the advanced stages of certain fevers, which, towards their close, are characterised by passive hæmorrhages; the blood being so thinned and broken down as to ooze, often copiously, from mucous surfaces. No symptom in the advanced stage of fever can be much more fatal than this.

It occasionally happens that, when the patient is reduced to a state of extreme anæmia, not only does a serous effusion take place, but also a tubercular deposition.

Master C., at 11, an ardent, energetic child; rather precocious in mental manifestations and feeling, and abounding in animal spirits; of florid complexion, plump, and well nourished; had been, previously to my first visit, treated for strumous tumefaction of the cervical glands. I found him vomiting violently: the vomiting, though mitigated by treatment, continued in a distressing and exhausting degree for three days; it then abruptly ceased, and he appeared better. On the following day he was deeply and universally jaundiced, with some fever, thirst, and epigastric tenderness, but was able to retain in the stomach light farinaceous nutriment. The inflammation had obviously departed from the gastric, and had invaded the duodenal mucous membrane, and thus obstructing the orifice of the biliary duct, had caused jaundice.

He continued in this state for many days; the yellow tinge then slowly and gradually vanished. During the whole of this period very little nourishment had been received into the system. He was now, however, apparently convalescent, though greatly reduced in flesh, strength, and animal spirits. After the lapse of a few days, a slight rigor ushered in fever; and this was soon followed by an

outbreak of erythema nodosum on both lower extremities. The patches were prominent, hot, painful, red, and irregularly circumscribed; they were of various dimensions, some being equal in size to a half-crown piece; and for three weeks they continued to appear in successive crops, some fading away, whilst fresh ones were coming out. Whilst the eruption lasted there was present, though varying in degree, diurnal fever of the remittent type. When convalescence was nearly re-established, the little patient, now very bloodless, pallid, and emaciated, began to complain of slight pains, not persistent below the inferior margin of the left ribs. These, at first, attracted but little attention; at length the pain became more fixed and permanent, higher up under the ribs on the left side, and much augmented by a deep inspiration; an effusion commencing below gradually extended itself upwards, till at length the dulness on percussion was universal, and the extinction of respiratory murmur complete. The heart was slightly displaced, and the thoracic dilatation sufficient to obliterate the muscular movements, and the depressions of the intercostal spaces. After a long period of dyspnoea, often amounting to orthopnoea, accompanied with harassing dry cough, sleeplessness, agitation, and general distress—painful even to witness—the chest fell in and became palpably contracted. Over a considerable space of the superior portion of the left lung, both anteriorly and posteriorly, respiration was re-established. The respiratory murmur, when first heard, was mingled with a small crepitus; by degrees the signs, local and constitutional, of tubercular disease, chiefly of the left lung, became more unequivocal, until no doubt could be entertained of the nature of the disease which brought this little boy to an early tomb. Prolonged wasting fever, and imperfect nutrition, rendered him exsanguineous; in this state he was attacked by pleuritis with effusion; nor was this all: coeval with the serous effusion was the deposition of tubercular matter in the parenchyma of the lungs. This disastrous event, masked at first by the effusion, but rendered subsequently manifest on the absorption of the effused fluid, stamped upon a case, otherwise not hopeless, an inevitably fatal character. Frequently during the progress of his illness, and on previous occasions, I had carefully examined the chest; and in no instance had I met with a more perfect example of sound lungs; of total exemption from any one sign, either local or constitutional, of preexisting crude or latent tubercle; so that no doubt was left upon my mind that the pleuritic effusion and the tubercular deposition were contemporaneous. I have seen and carefully observed many such cases, some of true chlorosis, others of superinduced anæmia, marked by the combined events of effusion into the sac of the pleura, and of tubercular deposition in the substance of the lung. In cases of this description I have known the operation of paracentesis proposed, and in one instance performed, when a careful analysis of the case would have rendered it certain, that the only possible result must be the infliction of a needless wound, with perchance a few days' prolongation of a miserable and suffering existence. On the subject of pleuritic effusions, some with, and others without tubercles in the lungs, I shall have occasion hereafter more fully to speak. I have not long since met with two cases of the double event alluded to, in young married women reduced to a state of extreme anæmia and debility by superabundant and too long continued lactation; they both terminated fatally, evincing before death indubitable signs of tubercular cavities; the local signs being most evidently marked on that side of the chest which had been the seat of pleuritic effusion.

In the foregoing remarks I have classed together cases of chlorosis and of anæmia. Between these two states there is a striking analogy; they both lead to the same pathological results; still, as I have before observed, they are not proved to be identical. Hæmorrhage, by no means unusual in anæmia, is not frequent in chlorosis. In cases of anæmia, serous and sanguineous effusions may and sometimes do occur simultaneously; whilst anasarca is present, if the patient be attacked with congestion or inflammation of the brain, lungs, or any other organ, an effusion of blood,

either circumscribed or diffused, may take place. A frequent cause of anæmia is hæmorrhage; but the hæmorrhagic action often continues, though the patient be already anasarctous and reduced to an extreme state of anæmia. Thus we occasionally meet with anæmia, hæmorrhage, and anasarca coexistent.

In chlorosis cutaneous eruptions are comparatively rare; in this respect the contrast with the hæmorrhagic diathesis is not a little remarkable. Upon the intimate connexion which exists between many varieties of skin disease and the hæmorrhagic condition, I shall hereafter have occasion, at some length, to dwell. There are on record, and I have, myself, met with, many instances of the alternation of cutaneous diseases, particularly of the eczematous kind, with hæmoptysis. In these cases, so surely as the exuding disease of the skin is either cured by art or spontaneously subsides, as certainly does the hæmoptysis return. In the hæmorrhagic condition, the superficial capillary system is often loaded with blood rich in red corpuscles, and various cutaneous eruptions are frequent; in the chlorotic state, this system receives comparatively few red corpuscles, and the skin is generally exempt from irritation and disease. To this general rule the exceptions are not numerous. In the treatment of many diseases of the skin this is a distinction of some practical importance; it frequently assists in pointing out the way which leads to the most effectual method of treatment. I have observed, in some cases, the outbreak of eruptions, particularly on the face, at that period when, the chlorosis having subsided, the opposite one of redness, flushing, and augmented mental and muscular vigour have been established.

Chlorosis has been traced to many sources; such as deep, long-continued mental emotions and sufferings; suppressed passions; sexual excesses and perversions; sudden cessation of the catamenia; profuse leucorrhœa; damp localities; impure air; transition from a rural to a city life; scanty and innutritious food; impressions of cold; sedentary occupations, and insufficient muscular exercise; copious and protracted hæmorrhage; and wasting and prolonged fevers. In short, its origin has been attributed to all causes capable of deteriorating the blood, depriving it of its due proportion of red corpuscles, and producing the state of anæmia. These, however, one and all, do but predispose to the disease; there are required in addition, a particular period of life and a particular condition of constitution, to produce it. Amongst the predisposing causes briefly enumerated, there is one which claims more particular notice; that to which I allude is the instinct of attachment, or as it is termed by the phrenologists, adhesiveness. Amongst the moral and educated portion of the female sex, I have noted many instances of the all-prevailing influence of this powerful instinct. It is implanted in the female mind more deeply than in the male. Besides, the busy and competing scenes of active life, in professional, laborious, scientific, or pleasurable pursuits, so distract the thoughts and attention of men, as to prevent the one prevailing thought from being constantly present before the mind. Not so with woman;—her lot in life is differently cast. The earnest and often necessary pursuits of men form generally but a fragment of female existence; and in the young, modest, retiring female there is nothing to break the current of her thoughts, or to interfere with the paramount influence of this strong, and, I will say, beautiful instinct. But, if it be the source of some of the most touching traits in the female character, it is often the source of unhappiness, ruined health, and premature dissolution. The attachment of the young female to the object of her affections is, of all mental influences, the most powerful; so powerful, as often to absorb and set at naught all other considerations. It is the sudden—often rude—disruption of a long cherished and, perhaps, concealed attachment, which undermines the health, prostrates the vital actions, and lays the foundation of hopeless and consuming disease. Too much stress is generally laid upon ungratified sexual instinct; it has its influence, and, in some minds, a powerful one; still, as far as my observation has reached, it is much frequently the cause of injured health

than a strong attachment abruptly broken. To this, as a starting point, I have been able to trace many cases of chlorosis; and when, in such instances, the strumous diathesis prevails, there are strong grounds to apprehend its ultimate issue in phthisis.

(To be continued.)

## Hospital Reports.

### THE LONDON HOSPITAL.

STRANGULATED INGUINAL HERNIA IN A FEMALE AGED 72;  
OPERATION; RECOVERY.

(Under the care of Mr. MAUNDER.)

E. N., aged 72, the subject of a double inguinal hernia, was admitted on January 24th, 1867, with the rupture on the left side in a state of strangulation. The patient was very thin, and the soft parts being very lax, the swelling hung over the upper and inner part of the thigh, and at first sight simulated a femoral hernia of unusual shape (ovoid). On examination, however, it was clear that the case was of the inguinal variety, inasmuch as the whole tumour could be carried to the inner side of the spine of the pubis, and its neck could be defined with comparative ease. Poupart's ligament was not well marked. The base of the tumour passed into the labium, and when the muscles bounding Scarpa's triangle were brought into action, it was evident that the tumour was not in this space but simply overhung it.

The stricture (very tight) proved to be at the mouth of the sac, necessitating the opening of the latter. The chief contents (bowel) were reduced, a portion of old adherent omentum being of course left down. No bad symptom followed, and the patient is convalescent, the wound having healed.

CARCINOMA OF GLANDS OF NECK FOLLOWING EPITHELIOMA OF TONGUE; LARYNGEAL; DYSPNOEA; TRACHEOTOMY; DEATH THIRTEEN DAYS AFTER.

(Under the care of Dr. Ramskill.)

From Notes by Mr. JAMES ADAMS, House-Surgeon.

William Bruce, 49, admitted January 22nd, 1867, was suffering during the year 1865, from epithelioma of the tongue, the diseased part of which was removed in December of that year by Sir William Fergusson. He remained free from disease until November, 1866, when he noticed a swelling on the left side of the thyroid cartilage, which rapidly extended, soon occupying the whole of the sub-maxillary and parotid regions. This was treated for some time by injection, under the care of Dr. Broadbent, without much benefit however. The tumour increasing, at length caused considerable difficulty in inspiration, which was accompanied by a loud crowing noise, and only accomplished by violent muscular exertion: expiration normal. On admission the breathing was in the same condition; the whole of left parotid and sub-maxillary regions occupied by a red, indurated swelling. Lips and face of a fair colour. It being considered advisable to open the trachea, he was placed in a room at a temperature of 70, the air being duly moistened by steam, and I proceeded to operate. When he was laid with the head thrown back, the difficulty in breathing was increased, and before the operation was finished he became livid, and then pulse and respiration ceased. I at once got the tube in, and artificial respiration was immediately commenced; and after a few minutes we had the satisfaction of seeing him take an inspiration. After this he fainted several times, and on the following morning, about seven, he ceased breathing again, but without any obvious cause (the tube being clear); Mr. Jones, the dresser, was immediately called to him, and, with artificial respiration, soon restored him. After this he went on very well, could speak easily, and took plenty of nourishment; the edges of

the wound became ulcerated; and after some days a fluctuating swelling appeared on the right side; this was opened, and discharged unhealthy-looking pus. A few days before death he became weaker, and gradually sunk on the 14th February.

*Post-Mortem.*—The left anterior upper triangles of neck were occupied by a hard mass, which had ulcerated superficially, and was also disintegrating in the centre; the disease also affected the parotid gland, and all the cellular tissue in front of the neck was much thickened. The larynx was still of its normal shape, so that it was evident that the dyspnoea, if caused by direct pressure, must have been owing to pressure on its posterior aspect; and on removing the larynx, there was found a deposit of the same nature as the rest of the disease in the submucous tissue over the left arytenoid cartilage; it was ulcerated on its anterior surface, and sufficiently moveable to fall within the aryteno-epiglottidean folds, and obstructed the upper opening of the larynx. The submucous tissue around was much thickened and infiltrated with serum.\*

The right circo-arytenoidens posticus was a very large, firm muscle; the left smaller, pale, and very flabby.

CASE OF COMPOUND COMMINATED DEPRESSED FRACTURE OF SKULL; TREPHINING; TEMPORARY PARALYSIS OF 6TH, 7TH, AND 9TH NERVES; PARTIAL HEMIPLEGIA OF LEFT SIDE, AND PARTIAL AN-ESTHESIA OF LEFT SIDE OF FACE.

(Under the care of Mr. CURLING.)

Reported by Mr. JAMES ADAMS.

Fred. Amos, 35, labourer, a man of temperate habits, was admitted on January 26th, with a compound comminuted fracture of the skull in the right fronto-parietal region; a portion of bone irregularly triangular in shape, about three inches in area, being depressed, and there were one or two fragments lying in the wound which were removed at once. He was in a semi-comatose state; but could be roused, and there was no paralysis.

Mr. Curling at once proceeded to elevate the depressed portion, which was easily done, after sawing off a projecting angle of bone; but the piece was found to be quite detached, and was removed. The dura mater was wounded to a very slight extent, there being slight laceration, about one-eighth of an inch long.

Soon after the operation the pulse rose to 120, moderately full, and by the 28th had fallen 70. He retained his consciousness, but was somewhat drowsy. On the 30th, the left pupil did not act so readily as the other, although there was no appreciable difference in size in a moderate light. Had a rigor in the evening. On the following morning there was paralysis of motion in left hand and arm. Also complete paralysis of 6th and 9th nerves, and incomplete of portio dura and portio mollis, and the left pupil became dilated. Order—Hyd. chlor. gr. iij. p. opii gr. ss. 4tis horis. wine  $\zeta$ vi.

February 1st. Has taken three doses of calomel and opium; and the bowels have been opened several times. Pulse 80, and weak; there is some return of power in left arm; wine increased to  $\zeta$ xii. The edges of the wound are surrounded by a slight erysipelatous blush.

He answers questions rationally, but when left to himself his mind wanders considerably.

February 2nd. Can move left arm readily; action of external rectus and facial muscles restored. The tongue, which is dry and brown, is still pushed somewhat towards the left side. He has vomited several times, and his bowels are much relaxed. Mist. astringens. Towards evening the diarrhoea and sickness abated.

February 3rd. The tongue is still dry and brown in centre, with red edges and tip; bowels acting very frequently; erysipelas spread over right cheek. He gradually became weaker, and died at six A.M. on the 4th.

*Post-Mortem eight hours after death.*—Rigor mortis per-

sistent. Large wound in scalp on right fronto-parietal region, leading through through an aperture in the bone, of an irregularly triangular shape, down to the dura mater, which was covered by a considerable quantity of pus, on removing which a small hole, about the size of a split pea, was seen in the dura mater. There was a considerable quantity of purulent fluid in the arachnoid, and the surface of the right hemisphere was covered with a greenish lymph, which was most abundant near the hole in the dura mater. The right anterior lobe was extensively lacerated. The sub-arachnoid spaces contained a large quantity of fluid, and on the left side a small quantity of lymph. In the substance of the right anterior lobe was a small clot. There was purulent fluid in the lateral ventricles, and the choroid plexuses were covered with lymph. The fracture was found to extend into right orbit, and across the middle fossa of the skull as far as the petrous bone.

## Reviews.

CLUB-FOOT: its Causes, Pathology, and Treatment. Being the Essay to which the Jacksonian Prize for 1864, given by the Royal College of Surgeons, was awarded. By WILLIAM ADAMS, F.R.C.S., Surgeon to the Royal Orthopædic and Great Northern Hospital, &c. Pp. 422. London: Churchill and Sons. 1866.

THE long period which Mr. Adams has devoted to the study and practice of orthopædic surgery, in which club-foot occupies a very prominent place, renders his contributions on such a subject most welcome to the profession, and the more especially as he has laboured to establish, not only the practical principles on which such deformities should be treated, but the theoretical and physiological laws which are concerned in their production, and which must be studied in all attempts for their relief. Nor, while according a just due of admiration to the brilliant discoveries of Delpech and Dieffenbach, and more especially to Stromeyer, must it be forgotten that the merits of tenotomy have in the present day been somewhat overrated, and Mr. Adams has proved that at least an equal degree of importance is to be assigned to recent improvements in the mechanical apparatus employed, as to the use of the knife, however skilfully it may be handled in the division of tendons. The fact is, that modern orthopædic surgery does not rely solely either on surgical operations or on mechanical appliances, but rather on a judicious selection of one or the other, according to the suitability of the respective cases, or on a combination of the operative and mechanical means, together with a well regulated system of gymnastics and special muscular exercises. It is the province of empiricism, rather than of true science, to exalt one of these methods above the rest, and to insist on its exclusive adoption; but surgeons of experience and reflection like Mr. Adams, examine carefully the valuable features in each, and apply them to individual cases as circumstances may suggest.

With reference, however, to subcutaneous tenotomy, which has undoubtedly been one of the triumphs of modern scientific surgery, the original experiments and dissections made by Mr. Adams have thrown a most important light upon the operations of nature in the repair of tendons, and consequently upon the processes which are set up after the surgical treatment of club-foot. Stromeyer and others considered that, by the division of the tendons, such a relaxation of the muscles was effected by a physiological action as to compensate for the previous shortening; but Mr. Adams has conclusively shown that the tendon itself is capable of reproduction or regeneration, and that the newly formed tissue acquires, within a few months of its formation, the structural characters of the old tendon so perfectly that it can be distinguished with difficulty even under the microscope. The greatest length of perfectly formed new tendon which he has seen was two inches and a quarter, in a girl aged ten. Mr. Adams also considers that the perfection of the reparative process is in direct proportion to the absence of extravasated blood and inflammatory exudation, and he regards the integrity of the sheaths of the tendons as a matter of importance, by preserving a connection between the divided ends of the tendon, by furnishing the matrix in which the nucleated blastemata or proper reparative material is effused, and by giving definition and form to the newly-

\* This case appears to me to be of much interest, as it was open to doubt whether the dyspnoea was produced by direct obstruction, or pressure upon the recurrent laryngeal nerve.

developed tendonous tissue. The time required for the formation of the new tendon is estimated at about a fortnight in well-nourished infants, at three or four weeks in an adult; but in atrophied, paralytic limbs, at not less than five or six weeks, and it is important in the treatment that gradual extension should be practised after tenotomy, in order to regulate the length of the new material during the period of its formation.

The study of the conditions under which club-foot makes its appearance, is a very interesting branch of inquiry, not only as a matter of scientific speculation, but also from its bearing on the practical management of this deformity, and Mr. Adams has devoted several chapters to the subject. He divides talipes into the non-congenital and the congenital, the former occurring much more frequently than the latter, the proportion being as three to two. The great majority of the non-congenital deformities of the feet depend either upon spasm or paralysis of certain muscles or groups of muscles, and are due to centric or eccentric causes, or in other words, either to disease within the brain or to some peripheral excitement, and as many of such cases are curable, and most are unattended with very serious results, they do not always fall under the notice of the surgeon. Frequently, however, by the long continuance of the morbid conditions, the limbs become permanently deformed, as when, for instance, the anterior muscles of the leg are paralyzed, and the heel is raised; the talipes being then caused not by active contraction of the posterior muscles, but in consequence of the loss of power of the anterior ones and an induced atrophy of the posterior, which latter are no longer required to be of their usual length. In treating of the congenital forms of club-foot, Mr. Adams relates the results of several dissections made by himself, and which prove, in opposition to the views of Scarpa, that in such cases there are several important deviations, both in position and form, of the astragalus. This bone is tilted obliquely forwards and downwards, and, to a certain extent, displaced from its socket, in consequence of the elevation of the tuberosity of the os calcis, and consequently, the anterior third, or more, of the superior articular surface of the astragalus is thrust on to the dorsum of the foot. This very important fact, together with the existence of other deviations from the natural form of the astragalus, is proved by the dissection of a foetal foot made by Mr. Adams, and by other dissections by him of deformed feet, and the peculiarities are exhibited in several illustrations made from the dissections.

Having thus briefly noticed some of the most important of the original researches made by Mr. Adams, we have only space to refer to the indications which he considers necessary in deciding on the operation of tenotomy in preference to any other modes of treatment. When the foot cannot be fully everted, or brought to a straight line with the leg by manipulation, and when, in the attempt to do this, the inner malleolus does not become prominent, and when the os calcis either cannot be depressed at all, or only to a slight degree, so that, after the partial eversion of the foot, little or no flexion at the ankle-joint can be obtained, then he regards the operation as absolutely necessary. We need scarcely mention that the mode of performing the operation, together with the after treatment, is fully described in subsequent parts of the work, and the effects of mechanical appliances and of physiological exercises all receive their due share of attention. In conclusion, we cordially recommend Mr. Adams' essay as a most able and exhaustive work on the subject of which it treats.

A PRACTICAL AND THEORETICAL TREATISE ON THE DISEASES OF THE SKIN. By GEORGE NAYLER, F.R.C.S., Assistant Surgeon to the Hospital for Diseases of the Skin, Bridge-street, Blackfriars. Pp. 292. London: Churchill and Sons. 1866.

NOTWITHSTANDING the great number of works already existing on diseases of the skin, Mr. Nayler does well in contributing another to this department of practical medicine, and his experience at the Bridge-street Hospital enables him to illustrate his remarks by examples drawn from actual cases. Amidst all the systems of dermatology which the prolific invention and ingenuity of modern writers have devised, that of Willan still holds its ground, and Mr. Nayler confesses that he is acquainted with none which, in point of utility, can supply its place. At the same time, no one supposes that this system is perfect; on the contrary, it is full of imperfections, but the same remark may be made of any system of dermatology or of nosology. For disease, after all, is not divisible, like the objects of natural history, into distinct classes and orders, form-

ing so many individual entities, but is rather to be regarded as a deranged condition of the human system, displaying itself in a thousand different ways, according to personal peculiarities of constitution, situation on the body, epidemic and climatic influences, and many other modifying or determining circumstances.

Mr. Nayler comprises, in accordance with the leading ideas of Willan, the squareness, the papular, the vesicular, and the pustular affections in so many groups. Other diseases, as lupus, elephantiasis, and alopecia, are arranged separately, but the author has not thought it expedient to place in a class by themselves these diseases which are considered to owe their origin and existence to the presence of vegetable parasites, as pityriasis versicolor, tinea tendens, and favus.

The illustrations consist of seven very well executed plates (two being coloured), representing the anatomical structure of the skin, hair, and nails; the blood-vessels of the skin, and those existing beneath the nail; the structure of some of the vegetable skin parasites; and the structure and development of the acari (acarus folliculorum and a scabiei); and there are a few other illustrations scattered through the book.

The treatment recommended for the different diseases is in all probability that adopted by Mr. Startin, whose clinical assistant Mr. Nayler was for some years at the Skin Hospital, and he could not well follow a better guide. The book is very well got up, the type is large and distinct, and the paper is tinted.

We should recommend Mr. Nayler to pay more attention to the spelling of scientific terms, more especially in a work which is intended, as he tells us, as a guide for students. Ichthyosis, for instance, is persistently spelt *ichthyosis*; herpes circinatus is spelt *circinnatus*; pompholyx is spelt *ponmpholix*; and the Greek etymology of eczema is given wrongly. These are not typographical errors, as the words are never spelt rightly, and their are many minor errors of the same kind, as Dr. Pereira figuring as *Pareira*; erysipèle printed for *érysipèle*; Kuchenmeister for *Küchenmeister*; liquor sodæ arsenitis for *liquor sodæ arsenatis*; and a large number of similar inaccuracies, which it appears strange should have escaped the notice of the gentleman whose services in revising the book in its passage through the press are gratefully acknowledged by Mr. Nayler.

#### CURRENT LITERATURE.

AMONG the most interesting of recent French publications is the *Dictionnaire Annuel des Progrès des Sciences et Institutions Médicales*, edited by M. Garnier, and of which the third volume, that for 1866, has just been issued by Baillière. It is, in fact, what it professes to be, a complete dictionary of the various contributions to medical science during the year. The alphabetical arrangement is certainly most easy for reference, and we are happy to find that the labours of Englishmen in the several departments are very fairly represented.

Under the title, MATTER—*Its Ministry to Life in Health and Disease*; and EARTH—the *Natural Link between Organic and Inorganic Matter*, Dr. Hawksley has re-published his views respecting earth closets, to which we some time since drew attention. Those interested in the question cannot do better than look over Dr. Hawksley's pamphlet.

Mr. Skey has re-published, in a separate form, his six lectures on hysteria, delivered last session at St. Bartholomew's Hospital, and which have previously appeared in a contemporary. As secondary titles are given to the work, we will quote the name of this little book in full. HYSTERIA: *Remote Causes of Disease in General; Treatment of Disease by Tonic Agency; Local or Surgical Forms of Hysteria, &c.* We have nothing to say against a hospital lecturer insisting on the use of wine in the treatment of disease or injuries; but surely Mr. Skey need not go beyond the walls of his own hospital to see that he is by no means the only surgeon who employs this agent. Does he really think it necessary to call the attention of

the profession to the *tonic treatment of disease*, or is it not rather late in the day to depict hospital surgeons as addicted to free depletion? If the book is intended for the public, it may serve to show that Mr. Skey will allow his patients full diet and a supply of stimulant; but we should have expected something above this from the Consulting-Surgeon to St. Bartholomew's Hospital.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Dublin, and Edinburgh, every Wednesday morning.

### THE INDECENT ADVERTISING QUACKS.

THE *Pall Mall Gazette*, which we noticed last week as commencing a most righteous crusade against one of the monster evils of the day—namely, the distribution of indecent quack advertisements in our leading streets and thoroughfares, continues to carry on with great spirit and ability the attack it has begun. Our contemporary, who is, of course, obliged to be somewhat reticent, from a regard to public decency, as to many of the grosser aspects of the question, very mercilessly lays bare some of the ramifications of the system it denounces. Originating with a set of pseudo-medical swindlers, or rather springing from several gangs of the same description, the machinery by which the nefarious trade of victimizing the timid, the nervous, or the imprudent, is carried on is by means of the great facilities afforded by the periodical press, by the transmission, through the post, of mendacious books and pamphlets, and by the exhibition of so-called museums of anatomy, which are simply dens of disgusting filth, where the arch-impostor, who exhibits the show, receives and fleeces his victims.

It might well be asked by any philosopher or philanthropist why such things are allowed to exist, for even if the laws of the country are insufficient (which, by the way, we very much doubt), to suppress the abuse, why is the public press, in general, silent upon the subject? It is certain that the silence is due to no squeamish regard for the morals of the community, for we find matters introduced into our public newspapers which might raise a blush on the cheeks of the least modest of men or the most immodest of women; and it is not from any feeling of

leniency for the quacks themselves, inasmuch as every other form of quackery, or supposed quackery, is remorselessly castigated by these self-appointed censors of the public morals. Let some respectable member of the Medical Profession fall into a pardonable error of judgment, let one medical man conscientiously differ in opinion from another; nay, let some honourable and perhaps learned medical man refuse to adopt the same views on some difficult point as are held by the so-called guides of public opinion, and forthwith the flood-gates of abuse are let loose, and innumerable are the sarcasms and the invectives hurled at the study and the practice of medicine by persons who, perhaps, really know nothing whatever of the subject on which they write. But the immunity of the indecent quacks, who trade in what are called secret diseases, is secured by the operation of a motive which reflects the utmost disgrace upon their protectors. The fact is, that many of the journals actually derive a considerable part of their profits from the insertion of the indecent advertisements to which we allude, and what is a most ludicrous, if it were not a disgusting feature in the management of many of these journals is, that some, which are the loudest in exposing what they conceive to be the social abuses of the age, are the greatest pecuniary gainers in this infamous traffic.

But, although it is bad enough that the advertising columns of some of the general newspapers should teem with the disgusting announcements in question, it is still worse that the sanctity of domestic life should be invaded by the books and pamphlets sent by the obscene quacks through the medium of the general post. Over and over again have respectable gentlemen of the clerical profession, and of the army and navy, written to the medical journals to repudiate the filthy trade, and to ask indignantly why the dissemination of such publications should be allowed; but the general Press is still silent, and the nuisance is allowed to proceed unchecked and uncontrolled. The *Pall-Mall Gazette* is almost the only journal which has ventured to grapple with the evil, and it deserves the thanks of the community for the courageous attempt.

It is sheer nonsense to pretend that the existing laws are insufficient to suppress, or, at all events, to diminish the monstrous evils resulting from indecent advertising and the transmission, through the post, of indecent quack books. If either of these modes of publishing were practised anonymously, there would necessarily be a difficulty in detecting the delinquents; but the fact is, that the publishers in both cases are always perfectly well known, and the very aim and object of the books and the advertisements is to make known some scoundrel or other, whose residence is always indicated in precise terms, although his name is usually a fictitious one.

Still, as it is no defence to an action for libel to plead the adoption of a false name on the part of the libeller, so the LISTONS, the BRODIES, the COOPERS, and the rest of the gang of indecent quacks, could easily be traced by prosecuting either the publishers of their trash or the proprietors of the papers which insert their advertisements.

The so-called anatomical museums, again, are the offspring of the present age, and owe their origin entirely to the ingenuity of the indecent advertising quacks. In these places the models and preparations are exhibited with the twofold object of stimulating the sensuality of the debauchee, or inflaming the passions of the young, on the one hand; and on the other, of representing the results of vice or folly in the most hideous and exaggerated shapes, in order to advertise the pretended skill of the quack-proprietor of the show, who in a back-room of the establishment waits to entrap the unwary. It is quite needless in a Medical Journal to remark that if any lay persons possess sufficient curiosity to desire an acquaintance with anatomy and pathology, the splendid museums of the Colleges of Surgeons in the different capitals of Great Britain are open to their inspection, and that the introduction may be easily obtained; but as these lines may fall into other hands besides those of medical men, the observation may be of service. The only possible excuse that might be offered for the continuance of the anatomical museum abomination is thus cut away, and we have no hesitation in stating that the police regulations at present in force might be made available for suppressing the nuisance if the authorities would only set their shoulders to the wheel.

As we hinted last week, the question has lately been taken up in influential quarters, and it is very probable that if no speedy means be adopted for putting a stop to the existing abuses the attention of the House of Commons will be drawn to the subject.

#### THE PROFESSORSHIP OF ANATOMY AND PHYSIOLOGY IN THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

THE Council of the College met on Thursday last, the 21st inst., pursuant to Charter, to elect a Professor of Anatomy and Physiology, in the room of Dr. ARTHUR JACOB, and a considerable number of the Fellows of the College were present to witness the election. According to the usual course of proceeding, numbers representing the twenty-one members of Council were put into a box, and of these seven were drawn to elect. The names of the seven members on whom the lot fell having been declared, the following very stringent declaration was administered to them by the President:—

“I, do solemnly and sincerely promise and declare, that I will to the best of my knowledge, skill and judg-

ment, without hatred, evil-will, partiality, affection, favour, or fear, justly, equally, and faithfully discharge the trust now reposed in me to elect the most fit and proper person to fill the situation of Examiner or Professor of

And, further, that I consider myself bound to elect the candidate who affords the most unquestionable proofs of good character and of ability, acquirements, industry and perseverance applied to the branch for which I am now called upon to elect a Professor or Examiner; and that I do not consider previous services in the College, in this or any other department as establishing a peculiar claim to a preference. And, also, that I have not, directly or indirectly, promised to vote for or favour any particular candidate.”

Having taken the affirmation they retired to consider their decision. On this occasion Dr. E. D. MAPOTHER, Professor of Hygiene [in the College, was the only candidate for the Chair, and he was accordingly declared duly elected.

Dr. MAPOTHER's name is already so well-known to our readers that it is almost unnecessary for us to enter into the claims put forward by him for his election to the honourable position to which he has attained. It is only necessary to say that within thirteen years from receiving his profession, and without the slightest impetus from personal or professional advantages, his untiring industry, ceaseless application, and great mental qualifications have placed him in one of the first, if not *the* first, rank as a teacher in the Irish School of Surgery. Commencing his medical career as a pupil of the late Dr. JOHN HATCH POWER, Professor of Surgery in the College, Dr. MAPOTHER now holds the Doctorate in Medicine of the Queen's University and the Fellowship of the Royal College of Surgeons. He is Surgeon to St. Vincent's Hospital, Public Officer of Health for Dublin, Professor of Hygiene in the College, and an Honorary Member or Office-bearer of the Epidemiological Society, the Metropolitan Association of Officers of Health, the Surgical and Statistical Societies of Ireland. As a writer, he has found opportunity to give to the Profession a Manual of Physiology, Lectures on Public Health, of which a second edition has just appeared; an Essay on the Hip-joint, for which he was awarded the gold medal of the Pathological Society, and many valuable contributions to THE MEDICAL PRESS AND CIRCULAR.

We have refrained, for obvious personal reasons, yet perhaps to the surprise of our readers, from any comment whatever on Dr. MAPOTHER's candidature previously to the election, in the belief that his merits would carry their own acceptance by the College. We are no longer forbidden to express our satisfaction at a selection of a successor to Dr. ARTHUR JACOB who cannot fail to impart an impetus to the School of the College, and afford a new guarantee to students for the efficiency of their staff of instructors. Truly, the Council might have selected an older man; but they have evinced in their choice

a regard for the interests of their School superior to religious or personal considerations. Dr. MAPOTHER has, both by his career as a private teacher, and as acting temporarily for Dr. JACOB, earned a character for thorough acquaintance with the subjects of the Professoriate, capacity for imparting instruction, and indefatigable perseverance in the discharge of his daily routine of duty which may well condone his want of years.

### Notes on Current Topics.

**RELATIVE LONGEVITY OF THE MARRIED AND SINGLE.**—Husbands are henpecked, it is said, and bachelors are bonny lads, and free. A man's doom is fixed when the marriage service is ended. Then he is bound for life, and must submit to all the whims, and caprices, and tempers, and certain lectures of his better-half. True, there is a Divorce Court, but the overwhelming majority can never get free again unless death extends a friendly hand; whereas, your bachelor is his own master, with nobody to control him, nobody to criticise, or utter a snappish word. He is a king in his castle, rejoicing in his absolution, and looking down in pity on his neighbours in marriage fetters next door. Divergent as these two states may be, there are equivalents which balance the good of the one against that of the other, and which, perhaps, were we to investigate, would show the advantage to be on the side of the married man. One test has latterly come under our observation, which no one can gainsay, and which we present to our readers. We quote the following figures from the report of Dr. Stark, of the Scotch Register Office, for the year 1863. From the age of 20 to 25 the death-rate of bachelors was found to be double that of married men, between 25 and 30 it was 13·7 per 1000 among bachelors, and only 8·6 among married men; from 30 to 35 it was 14·7 against 9 per 1000, and so on, the difference gradually lessening every five years, but never becoming totally lost, so that from 60 to 65 the death-rate of bachelors was 43·3 per 1000, against 38·8 of married men. Or taking the average age of the two, respectively, from twenty years to the close of life, that of the married was 60 years, of the bachelors only 40 years; or, as a better and fairer period, from the 25th year to the close of life the mean age of married men at death was 60·2 years, that of bachelors 47·7. Thus a man who marries will probably live eleven years longer than if he remained single. What is there then in the married state—for something there must be—which renders it more conducive to longevity than single blessedness? May we not fairly infer that it yields more contentment, more comfort, more satisfaction, and consequently more happiness than the other; and that these things have a conservative bearing upon the health? Be it as it may, when a man has some one who reciprocates his affection, welcomes him home, rejoices in his prosperity, cheers him when depressed, in fact, who is the light and life of his dwelling, he must be in all respects in a far better condition than he who lives uncared for and alone.

**VACCINATION IN SCOTLAND.**—The act which came into operation 1st January, 1864, and enacts that every child born in Scotland after that date must be vaccinated within six months of its birth, bears rather hard upon the poor;

while it imposes a penalty for neglect, it prescribes a fee of 1s. 6d. to be paid by the friends of the child to the public vaccinator. His services are gratuitous only in case of pauper's children. Now there are numbers of the people in exceedingly straightened circumstances, though not actually paupers, who are unable to pay the fee; but they can only obtain gratuitous vaccination after having incurred the penalty of twenty-one shillings for breach of the law. Still, as they cannot pay, the defaulters are numerous, as is seen in the annual report of the Board of Supervision for the year ending June 30, 1866. These returns do not include cases in private practice. In the whole of Scotland there were 13 successful cases to 10,000 of the population. The proportion was highest in the following counties:—Wigton, 58; Caithness, 53; Forfar, 46; Inverness, 33; Aberdeen, 25; Argyle, 22; Dumbarton, 15. The lowest proportions were—Kinross, 1; Roxburgh, 1; Clackmannan, 2; Sutherland, 3; Perth, 3; Berwick, 3; Bute, 4; Edinburgh, 5; Lanark, 6. The large number of 2092 defaulters was recorded in Lanark, being 33 per 10,000; in Renfrew the proportion was 28; Edinburgh 14; Aberdeen 3 per 10,000. It is to be hoped that the suggestion of the Registrar-General for Scotland that the act be amended will be adopted, so that those who cannot pay may be able to have their children done free.

**UNIVERSITY OF CAMBRIDGE.—SCHOLARSHIPS FOR NATURAL SCIENCE AT SIDNEY SUSSEX COLLEGE.**—There will be an examination at this College on October 8th, in Natural Science (electricity, chemistry, geology, and anatomy), for two Scholarships of the value of £40 per annum each. It will be open to all who shall have been entered on the College Boards, before October 1st. Further information may be obtained from the Rev. J. C. W. Ellis, tutor of the College. Mr. Walker, who was admitted first in the Natural Science Tripos, last December, has just been elected a Bachelor Scholar of the College, Superintendent of the College Laboratory, and Natural Science Examiner. There is, we understand, at this College a considerable fund available for the promotion of Natural Science, so that students who deserve encouragement, are pretty sure to meet with it.

**ANOTHER PRINCESS.**—Last Wednesday morning the Princess of Wales was delivered of a female child. As Her Royal Highness had been suffering some days from acute Rheumatism, some anxiety for her has been exhibited throughout the country. As on previous occasions the confinement was not expected to take place until a later period, and it is not improbable that, but for the painful illness under which the Princess was labouring, parturition might have been postponed for another month. Mother and child are progressing favourably, and we hope the last traces of rheumatism may soon disappear.

**PRESENTATION OF THE COPLAND TESTIMONIAL, LONDON HOSPITAL.**—On Monday, February 18th, a meeting was held in the Anatomical Theatre of the London Hospital Medical College for the purpose of presenting to Mr. Oswald Copland a valuable watch as a token of their admiration of his gallant conduct at the late calamitous accident in Regent's Park. The chair was occupied by the Rev. T. J. Rowsell, M.A., who in a very able speech brought the particulars of the event before the meeting, and commented on the heroism and modesty of Mr. Cop-

land, and also the pleasing unanimity and liberality of those who, wishing to show their appreciation of this brave man's conduct, had opened their purses as well as their hearts, and had thus the gratification of presenting him with a suitable and lasting token of their gratitude. The word gratitude was well-chosen, for every one of his fellow-students and superiors must feel a vast deal of pleasure and thankfulness in being able to count him as one of them; regarding the successful attempt to save life, not only as affecting him now, but also as a forerunner of a long career of hard work, an indication of indifference to danger whenever met, and a stern sense of duty, which must merit, if not secure, professional success. Mr. Copland expressed his acknowledgments, and a vote of thanks to the chairman terminated the proceedings.

**WATER SUPPLY OF LONDON.**—An interesting paper on this subject was read last week by Mr. Thomas Beggs before the Society of Arts. Without ignoring those considerations relating to health, comfort, and cleanliness on which we have so often dwelt, Mr. Beggs devoted his chief attention to other reasons for demanding an improved supply. Of these we may mention the utter inadequacy of the existing arrangements in case of fire. Why should not London have a constant supply of water at high pressure, and why should not hose be kept ready in all large establishments? Norwich, Wolverhampton, Nottingham, and other large towns have a constant supply; if London had the same, half the property destroyed by fire might be preserved. Mr. Beggs advocated the plan of bringing the water from the Cumberland lakes, as in his opinion the most practicable, and he would make the several metropolitan, parliamentary boroughs corporations for the purposes of general government, considering that such corporations could easily contract with existing and new water companies, or make other arrangements for an efficient supply.

**PAYMENT OF MEDICAL OFFICERS FOR CHOLERA ATTENDANCE.**—It will be remembered that the Medical Officers of the North Dublin Union were offered by the Board of Guardians a fee of one guinea for every day on which they were on special duty at their dispensaries, no allowance being made for the extra duties discharged by them on other occasions during the epidemic. Several of these gentlemen, feeling that they were not well treated, declined the offer altogether, while others accepted it with the reservation that they regarded it only as part payment. An appeal to the Poor-law Commissioners from the Medical Officers has resulted in the following letter:—

“POOR-LAW OFFICE, CUSTOM HOUSE.  
“February 19th, 1867.

“The Commissioners for administering the Laws for relief of the poor in Ireland transmit to you herewith copies of two communications which have been addressed to them by Medical Officers of the North City Dispensary District, on the subject of the amount of remuneration awarded to them by the Board of Guardians for extra duty during the late prevalence of cholera and diarrhoea in the district, and the Commissioners request that they may be favoured with the observations of the Board of Guardians on the subject. The Commissioners desire, at the same time, to point out, that by the general regulations of the 25th August last, it is provided that the Medical Officers shall receive the remuneration for their services under the order, in proportion to the nature and extent thereof; and, in the opinion of the Commissioners, the extra remuneration should have reference to the whole time

during which time cholera and diarrhoea were dealt with under the order, that is to say, during the continuance of the epidemics. By the 65th Section of the Sanitary Act, '66, the Guardians are empowered to determine, subject to the approval of the Commissioners, the amount of remuneration to be awarded for extra medical services performed under the direction and regulations of the Commissioners; and the Commissioners are empowered, if they shall not approve the amount determined by the Guardians, to fix the remuneration, by order under seal, proportioned to the nature and extent of the service.

“By order of the Commissioners,

“B. BANKS, Chief Clerk.”

We accept the declaration of the Commissioners, that “the extra remuneration should have reference to the *whole time* during which cholera and diarrhoea were dealt with under the order—that is to say, during the continuance of the epidemic,” as a complete verdict in favour of the claims. It is to be regretted that the Guardians, who, we believe, as a whole, would be anxious to act liberally towards their Medical Officers, should abrogate their sense of justice at the bidding of a few members who never give but grudgingly and of necessity.

**THE LATE MR. THOMAS MARTIN, OF REIGATE.**—The death of Mr. Martin, of Reigate, although an event which has occurred in the course of nature, is one which should not be allowed to pass without respectful comment on the part of the medical journalist. Although nominally occupying only the position of a provincial practitioner, Mr. Martin was an accomplished scholar, a finished gentleman, and a true and practical philanthropist. In every movement, having for its object the welfare and advancement of the Medical Profession, he took an active and permanent part. The association formed in 1812 for the improvement of the status of the general practitioners, and the President of which was Dr. G. M. Burrowes, counted Mr. Martin as one of its most zealous members; he was equally energetic in promoting the establishment of the Provincial, Medical, and Surgical Association, now the British Medical Association; and he subsequently, under the Presidency of the late Mr. Pennington, was an active member of the Institute of Medicine, Surgery, and Midwifery, the object of which was to obtain a Medical Reform Bill. The societies which he started in his own very neighbourhood for the friendly intercourse of the profession, for the improvement of the condition of the poor, and for the advancement of education are so many existing monuments to the kindness of his heart, the enlarged sphere of his sympathies, and the energy of his character.

**OFFICIAL RECOGNITION OF THE PROFESSION.**—We have always advanced the principle, that the status of our Profession does not rest in ceremonialism or pomposity, but rather on services of value rendered to the public. We cannot, however, permit it to be forgotten that, as a body, including many thousands of highly-educated gentlemen, our Profession is entitled to the same consideration which politeness accords to the kindred ranks of Law and Divinity; and when occasions of ceremony occur, and honour is done to the Law, the Church, the Army, or Navy, the representatives of medicine ought to receive the same regard. We observe that, at the late Municipal Banquet at Dublin, amongst the toasts of the Bar, the Church, Provincial Corporations, the Solicitors, and the Press, the Medical Profession is not mentioned at all, although both the President of the Royal College of Surgeons, and a

gentleman holding a high official position in the King's and Queen's College of Physicians, were sitting within a few feet of the Lord Mayor himself. Every profession received its full share of honour but ours, yet no profession had a better claim to public and official recognition. We cannot forget that this was not a mere oversight, because we are aware that on one occasion the President of the College of Physicians asserted his position by leaving the room, and on others the toast of the Medical Profession was placed in a position of neither honour nor dignity in the toast master's list. The representatives of our Medical Corporations did not, of course, anticipate this omission, but it will be in future for them in whom repose for the time the maintenance of the dignity of our Profession to ascertain before hand the part which they are to play, and, if necessary, to mark their sense of the slur cast upon them by their conspicuous absence.

#### THE HORRORS OF CHIGNONS.

THE alleged discovery of the parasites called *Gregarines* in the artificial chignons now so common has given rise to not a few very sensational paragraphs. One enthusiastic correspondent of a morning contemporary, signing himself INVESTIGATOR, thus describes the results of his examination, under a powerful microscope, of a chignon "purchased at a fashionable hair-dresser's:"—

"From the mass of hair composing the chignon I selected for experiment about 150 hairs, and commenced by carefully cleansing them from grease and other impurities in a tepid solution of potash, and drying them in a current of heated air. Upon submitting them to examination by a moderate power, I found the hair, which was of a dark brown colour and fine texture, perfectly clean and free from any parasitical appendages, until within half an inch of what was evidently the natural end of the hair; when a multitude of small dark knots or protuberances on the outer cortical were visible. Upon carefully detaching some of these—an operation of great difficulty and delicacy—and placing them on an object-glass under a much higher power, it was immediately evident that they were innumerable specimens of the so-called "gregarines." As nearly as I could estimate, half an inch of a single hair would yield over a thousand of these disgusting epizoa in their embryo condition, and enveloped in a glutinous substance. Having thus satisfied myself of their existence, I next proceeded to ascertain if they were possessed of vitality, and if so, how it might be called into action, and by what means, chemical or otherwise, destroyed.

"Now it is well known that gentle and continued heat affords the most favourable conditions for the development of this class of insect life. I therefore placed about a dozen ends of the hair between two pieces of felt slightly oiled, and submitted it to a moist heat of 120° for six hours; and also bound upon the neck of a common hen—a convenient place having been carefully shaved for the purpose—a number of hair-ends, and placed the bird in front of a stove for about the same time. At the end of this period the 'gregarines' which had been placed in felt were carefully examined. They had undergone great development, and more than a score showed unmistakable signs of life. But on removing the hairs from the neck of the hen, and placing them under the microscope, a most extraordinary change in the ova appeared to have taken place. The hairs were swarming with the released epizoa; nearly all, indeed, were more or less detached from the envelope, and presented many of the unmistakable peculiarities of the pediculus humani capitis.' In many the mouth was furnished with a proboscis, the antennæ as long as the thorax, and the depressed segments of the abdomen, were clearly visible. It was abundantly evident that no process to which the hair had as yet been submitted had even impaired, much less destroyed, the vitality of the 'gregarines.'

"I cannot venture to trespass upon your space by giving a detailed account of the experiments made to ascertain how this vitality could be destroyed; suffice it to say that steeping in boiling water, and exposure to a dry heat of 360° Fahrenheit, totally failed to do so. The compound ethers, benzole, and the

bichloride of mercury destroyed them completely; as also some of the mineral acids; but most of these would of course render the hair worthless to the chignon-maker, the beauty of its appearance being entirely destroyed. I regard these experiments as fully demonstrating the fact, that many ladies are wearing, perfectly unsuspected, upon their heads the germs of an insect life which may at any moment spring into a vitality that would prove distressing beyond measure, and be by no means easy to eradicate: these horrible insects multiplying with almost inconceivable rapidity, and their generation being governed by no well ascertained law. Moreover, it is a question for the medical faculty, and it is well worth considering, whether the rumoured reappearance of the most horrible disease, *phthiriasis*—common among the ancients, and of which Herod Antiochus, Callisthenes, and Sylla perished—is not owing to the wholesale wearing of the hair of the filthy Bur-lakes, of which so much is daily imported: the *Phthirus*, though of a different genus from the *pediculus capitis*, yet much resembling it in many radical points."

### Proceedings of Societies.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEB. 12TH, 1867.

Dr. JAMES ALDERSON, F.R.S., President.

#### ON THE NATURE OF THE WAXY, LARDACEOUS, OR "AMYLOID" DEGENERATION.

By WILLIAM H. DICKINSON, M.D. Cantab., F.R.C.P.,

ASSISTANT-PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN.

THE organic change formerly described as "waxy," latterly as "amyloid," affects many parts of the body at the same time. It consists of a morbid deposit first occurring in the walls of the small arteries, afterwards penetrating their coats and infiltrating the neighbouring tissues. It may be recognized by the action of iodine, which gives to the affected parts a reddish-brown colour, instead of the yellow tint which the same reagent bestows upon the healthy tissues. The solid viscera are increased in bulk by the exudation, while the same change in the mucous membranes renders them liable to extravagant secretion. The change was described in detail in the kidney, and shown to consist of a fibrinous exudation into the substance of the organ, and into the tubes in the form of casts. The casts are sometimes susceptible of the characteristic reaction. The conclusion that the material is essentially fibrinous was based upon the results of ultimate analysis, the contractile tendency of the deposit, its convertibility into fibrous tissue, and its apparent identity with fibrinous casts.

The disease was considered as affecting the whole body—not as confined to any particular organ. In the place of the general belief that the disorder is associated with tubercle, syphilis, or some other cachexia, it was shown that in a vast majority of cases it is produced by the loss of pus, or of some analogous discharge.

This view was based upon an analysis of 60 cases of the "amyloid" or waxy disease which came under the observation of the author. In 52 of these the change was apparently associated with the formation of pus. In detail, there were 47 cases out of the 60 in which there was direct evidence of profuse and long-continued suppuration. In 5 the post-mortem appearance were such as to lead to the inference that a loss of pus had taken place at some antecedent period. Excepting in the concurrence of suppuration with "amyloid" change, these cases had no resemblance to each other. Syphilis had existed in some, tubercular diseases in others, while in several there was no evidence but of local mischief. In 8 cases in which there was no evidence bearing upon the ostensible discharge of pus, there were 4 in which there was reason to believe that there had been albuminuria of the kind connected with tubular nephritis, the quantity of albumen being very large. A drain of albumen by the urine is equivalent in some respects to a discharge of pus. There remain 4 cases in which, from the imperfection of the notes and other circumstances, the disorder was not traced to its source.

The conclusion which associates the "amyloid" or waxy infiltration with the suppurative process was tested by an examination of the cases of the disease recorded by Dr. Wilks and Grainger Stewart. These writers have together reported 109

cases in which the body was examined and the antecedent disease was traced. Eighty-three, or more than three-quarters, depended upon undoubted loss of pus, while in the remaining 26 the disorders are of such a nature that it is not possible to doubt that suppuration must have existed in the majority, if not in all. It is sufficiently striking that so large a proportion should have been mentioned as associated with suppuration considering that these authors appear to have recorded their cases without particular regard to this condition.

The connection between the discharge of pus and the so-called amyloid deposit is such that more or less of the organic change may be predicted whenever the long continuance of suppuration has been ascertained. The view that the disease is necessarily associated with syphilis, tubercle, or any especial cachexia, is disproved by several of the cases recorded. In one case it came on in consequence of suppuration from dilated bronchial tubes, in another after suppuration from a compound fracture, in a third from profuse discharge after an amputation, in two after pelvic abscess consequent upon labour.

The fact having been established that the removal of pus from the system causes a deposition of the characteristic material in the organs, the nature of the connexion was examined. Pus is an albuminous fluid which is alkaline, owing to the presence of potass and soda. The alkaline and earthy salts of pus amount, on an average, to 1 per cent. of the discharge; of this, the salts of potass and soda form about nine-tenths. Details are given showing that the proportion of alkaline salts in the secretion is greater than in the corresponding blood, and it was shown how large an amount of alkali is by this means removed from the system. A discharge of pus is equivalent to a removal from the blood of albumen and alkali.

The characters of the "amyloid" deposit formed the next branch of the inquiry. Essentially consisting of fibrin, it remains to be seen on what the peculiar reaction depends. Ordinary fibrin is coloured yellow by iodine, as are the healthy tissues; while the "amyloid" deposit takes the characteristic deep-brown. It was shown that if the diseased tissue were allowed to absorb a small quantity of potass or soda the peculiar reaction was destroyed, the tissue afterwards behaving in all respects as in health. This power of destroying the "amyloid" reaction is confined to potass and soda.

It was next shown that the "amyloid" deposit has a distinctive action with sulphate of indigo. Healthy tissue destroys the colour, while the "amyloid" retains it. The power of destroying the colour of sulphate of indigo is due to the free alkali present in the healthy tissue, absent from "amyloid."

Next were given the results of analysis of healthy and "amyloid" livers, in which it appeared, from the examination of seven healthy and seven "amyloid" organs, that the latter contained a proportion of alkaline salts diminished, on an average, by one-fourth, the potass and soda being diminished equally.

Finally, it was shown that the "amyloid" substance could be made artificially out of fibrin or albumen by removing or neutralising the alkali with which they are combined. This artificial "amyloid" matter was shown to the Society, and had all the reactions with iodine and indigo which are characteristic of the morbid deposit.

The following were stated as the conclusions of the inquiry. The so-called "amyloid" deposit consists of dealcalised fibrin.

It is not necessary to repeat the reasons for supposing the deposit to be fibrous.

That it is wanting in an alkali is shown by these considerations:—

1. The morbid deposit loses its characteristic reactions when it has been allowed to absorb potass or soda.

2. Organs containing this deposit yield on analysis a smaller proportion of the alkalies than do the same organs in a state of health.

3. Ordinary fibrin or albumen can be made to exhibit all the peculiarities of "amyloid" tissue by depriving them of alkali by artificial means.

The morbid deposit is of the nature of a residuum. It occurs in cases where the system has been drained by an alkaline and albuminous discharge, the blood, therefore, retaining an excess of fibrin with a deficiency of potass and soda.

The most frequent cause by which this deposit is produced is suppuration—a cause which is active certainly in five cases out of six. The loss of albumen by the urine has a feeble action of the same kind.

The term "amyloid" must fall into disuse as founded upon error. The author proposes the word *depurative*—depending

upon the removal of pus—as fitted to describe the disease. The frequency of the change, the generally obvious nature of its cause, and the readiness with which it is detected during life, combine to give it great practical importance. It supplies a large proportion of the albuminuria which comes under the care of the physician, and is of constant occurrence in surgical wards, modifying the course of disease and the results of operations. A suggestion may be made with regard to patients subject to a purulent discharge. The food may be regulated so as to compensate, as far as possible, for the loss of albumen; and liquor potassæ and liquor sodæ may be given so as to make up for the loss of alkali.

Mr. GANT asked if this so-called amyloid deposit could actually be converted into fibrous tissue or even into fibrin, seeing that it was already a degeneration. He remarked that if it could be shown that there was a distinct connexion between the occurrence of this degeneration and prolonged suppuration, it would be of very great importance.

Dr. MURCHISON had received great pleasure in listening to Dr. Dickinson's paper, and would state his opinions more especially as to the practical points involved in it. He doubted if the degeneration was so very frequently associated with previous suppuration, although there could be no doubt of its often being so, especially with suppuration of bone. On referring back to his own cases, he found that some had no history of suppuration, but instead of it constitutional syphilis or ague. As to the treatment which would be founded on Dr. Dickinson's theory, his was quite the reverse; instead of alkalies, he relied on mineral acids, which he looked on as among the best remedies in such cases, as they invariably effected a great improvement in the system. With regard to the substance deposited in the tubules of the kidney, he looked upon it as fibrous instead of being amyloid, and he would remark that the urine was not alkaline in those of his cases where it was tested.

Mr. HOLMES referred to the frequency of the association of this degeneration with suppuration, especially of bone, and considered this an additional argument for getting rid of the diseased bone as soon as possible. He thought that many lives and limbs were sacrificed by neglect of this rule; for in his opinion it was advisable to remove the diseased structure before the constitution became affected, as he thought that many of these diseases were originally local, but became constitutional from their protracted influence on the system. Billroth had pointed out that external disease produced internal degeneration, and had operated on the former for the relief of the latter.

Dr. HEADLAM GREENHOW said it was a good thing to investigate the chemistry of disease, but he objected to the statement that suppuration was the invariable cause of amyloid degeneration, as he had lately had two cases, in one of which there was extensive amyloid disease, yet there had been no suppuration for twenty-three years, though the man had suffered from syphilis two years before that time, and had been affected with rheumatic fever and ague since the former period. Another had been perfectly healthy until his abdomen began to enlarge, and in this instance there was no history of syphilis. These cases, however, did not entirely disprove Dr. Dickinson's views.

Dr. PAVY considered the term amyloid to be a very bad one; the material effused was neither contractile nor organisable. In the spleen it was found in masses of a granular character, and without any organisation. In the liver it was generally diffused, the cells of that organ becoming angular by its means. He objected to the term *depurative*—first, because there might be suppuration without amyloid disease; and secondly, there might be lardaceous organs without preceding suppuration.

Mr. SOLLY said that the facts elicited showed the importance of early operation in disease of bone, and spoke of a case of disease of the hip-joint which had apparently induced lardaceous liver.

Dr. A. P. STEWART had had two cases—one fatal, the other improved. In neither was there the history of any suppuration of importance; in one none at all. In treating such he chiefly relied on the mineral acids. He asked whether the albumen in the urine was the cause or consequence of the disease. In both his cases albumen had been present.

Dr. DICKINSON thanked the Society for the way it had received his paper. In reply to Mr. Gant he stated that all fibrous structures become thickened by the effusion, and the changes can be seen going on in all stages. He agreed with Dr. Murchison that there were many cases without the history of previous suppuration. All he contended for was that such a history would be found in a majority of cases. Referring to

Dr. Greenhow's remarks, he objected that in one of his cases there had been no post-mortem examination. As to Dr Pavy's statement that the substance was not contractile, he would refer to the condition of the liver and kidneys in a recent case, for in the more chronic cases they became enlarged. With regard to the treatment by acids, that was in the more advanced stages, where they would do good as tonics; it was only while suppuration was going on that he would propose alkalis.

### CAMBRIDGE PHILOSOPHICAL SOCIETY.

MONDAY, FEB. 18.

A COMMUNICATION was made by Dr. Airy, the Astronomer Royal, "On the Continued Change in an Eye Affected with Peculiar Malformation."

Professor HUMPHRY read a paper "On Some Points in the Anatomy of Chimpanzee, and the Consideration of the term 'Quadrumanous,' as applied to that Animal." His remarks were the results of the recent dissection of two Chimpanzees and referred chiefly to the differences between their lower limbs and those of man. He pointed out that the outer condyle of the thigh bone is round instead of being prolonged from before backwards, and flattened beneath, as in man. Hence there is comparatively little security afforded by the ligaments in the straight position, and little provision for the maintenance of the erect posture. The bones and joints of the ankle were shown to be constructed so as to permit free movement rather than to bear weight. With regard to the term "hand," and the objections which have been urged to its application to the lower limb of the monkey, Professor Humphry remarked that if we use the term to designate a certain modification of the fore limb—a certain deviation, that is, from the ordinary fore foot—we may with equal propriety apply it to a corresponding modification of the hind limb—a corresponding deviation; that is from the ordinary hind foot. We must not expect it closely to resemble the human hand but merely to present such a similarity to it as the special features of a hand—viz., the shortness, mobility, and opposeableness of the thumb and the relative length of the other digits, would give it. Judging by this rule, it is as correct to speak of the "hind hand" of a monkey as of the "fore hand," though, forasmuch as both are employed in progression, it may, perhaps, be better to use some other term, such as "cheiropod" for the designation of the class, leaving the term "bimanous" to indicate the characteristic feature of man. The psychical qualities should not be omitted in considering the distinctive features of man; and the importance of the long, strong, firm great toe in this respect was pointed out. Some other peculiarities in the limbs and in the prostate gland of the Chimpanzee were described.

The paper will appear in the next number of the *Journal of Anatomy and Physiology*.

### BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE annual meeting of the subscribers to the above Society was held on Wednesday, 6th inst., in No. 33, High-street. Owing to the great severity of the weather, the attendance was not so large as otherwise might have been expected. Amongst those present were—Dr. T. H. Purdon, the permanent president of this branch; Dr. Drennan, Dr. Moore (James), Dr. Browne, R.N.; Dr. Wilberforce Arnold, Dr. Whitaker, Dr. Bryce Smith, and Dr. Stewart. The chair was filled by Dr. T. H. Purdon.

The proceedings of the last annual meeting were read and confirmed, and signed by the chairman. A statement was made of the operations of the Society during the past year—these extending over the Counties of Antrim and Down, and according to which it appeared that, though as compared with former years, the proceeds in the aggregate had not fallen off, yet they were not as large in amount as might fairly have been anticipated, and as the peculiar and important objects of the Society so eminently deserved. The statement above referred to regretted that so many members of the profession afforded no assistance to the Society, and that so few of the wealthy gentry gave of their abundance in a cause in which their support and sympathy were naturally looked for, and whose countenance would so materially help on a society which had such strong claims on those outside of the profession.

The following subscriptions and donations were then reported as having been received:—The Marquis of Londonderry, £5;

Dr. A. A. Stewart, staff assistant-surgeon, £2 4s.; Dr. Charles Mosse, staff surgeon, £1 1s.; Surgeon M'Bride, Gilford, 10s.; Assistant-Surgeon James Stewart, R.N., 10s.; Dr. T. H. Purdon, £25 (donation); do., £5 (annual subscription); Dr. W. Arnold, £2 2s.; Dr. Drennan, £1 1s.; Dr. B. Smith, 10s. 6d.; Dr. Moore (James), £1 1s.; Dr. Brown, R.N., £1 1s.; Dr. Doran, Kenmare, per Dr. T. H. Purdon, £1 1s.; Dr. Stewart, £5 (donation); do., (annual subscription); Dr. Patterson, £1 1s.

Dr. Moore having rendered very effective service during the past year, in obtaining subscriptions from the profession and others in the country, he was thanked heartily for the same, and requested to use his influence this year in the country parts as might suit his convenience, in promotion of the interests of the Society, which he kindly consented to do.

A committee of management for the ensuing year was appointed as follow—viz., Dr. Patterson, Dr. Drennan, Dr. Moore (James), Dr. Ferguson, Professor Cuming, M.D.; Dr. Wilberforce Arnold, and Dr. Whitaker for Belfast. Dr. Filson, Portaferry; Dr. Musgrave, Lisburne; Dr. Sparing, Antrim; Dr. Ross, Ballymena; Dr. Keown, R.N., Sydenham; Dr. David Taggart, Carrickfergus; and Dr. Malcomson, Banbridge, to represent the country localities of this branch.

Dr. Browne, R.N., was reappointed treasurer, and Dr. Stewart honorary secretary, and the thanks of the meeting voted to them for their past valuable services. On the motion of Dr. Stewart, seconded by Dr. W. Arnold, the marked thanks of the meeting were also cordially given to the conductors of the local newspaper press for their unvarying kindness, and readiness at all times in affording the benefit of their well-appreciated aid on behalf of the Society. Some further business having been transacted, Dr. T. H. Purdon was moved out of the chair, and Dr. Moore called thereto, when it was moved by Dr. Wilberforce Arnold, seconded by Dr. Drennan, and passed by acclamation, that the best thanks of the meeting be given to Dr. T. H. Purdon, the permanent president of this branch of the Society, for his dignified and able conduct in the chair to day, and for the continued warm interest he took in the promotion of its best interests, as well as for his always munificent contributions in carrying out the practical working of its humane and philanthropic objects.

The meeting then separated.

## Correspondence.

### CATHARRHAL INFLAMMATION OF THE TYMPANUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the MEDICAL PRESS AND CIRCULAR of last week I observe an extract from the *American Journal of Medical Science*, on Catarrhal Inflammation of the Cavity of the Tympanum in young persons, by Dr. Roosa. You remark on these cases that they prove very amenable to treatment. In this you are quite correct; but it is a singular fact that, it is the worst cases only that are cured, for the great majority, those not of a very severe character nevertheless ending often in confirmed deafness, are not subjected to treatment, except, perhaps, to home remedies of a doubtful or injurious character. Dr. Roosa is right in laying great stress on the importance of constitutional remedies, as is evident from the circumstance that the patients generally exhibit the strumous diathesis. Still, I am glad to find he does not overlook local treatment at the same time.

The deafness which attends these cases, almost from very commencement of the attack, will be far less likely to leave its traces behind if proper local, be combined with constitutional, remedies. Politzas' method of inflating the tympanic cavity is a step in the right direction; but as Dr. Roosa says, "at first the improvement only lasts for a short time." I hope he will take an early opportunity of using medicated spray, or, as it is termed, atomized lotion, in such cases. Weak solutions of nitrate of silver, sulphate of zinc, borax, lig. potassæ, &c. In the cases to which he refers as being benefitted by the vapour of iodine injected through Politzas' tube, I should like him to try solution of iodide of potassium, about four grains to the ounce, in the form of spray. Ten drops of such solution will be sufficient for one application to the cavity of the tympanum and Eustachian passages.—I am, &c., EDWARD BISHOP, M.D.

## Parliamentary Intelligence.

HOUSE OF COMMONS.—FEB. 18TH.

FLOGGING IN THE ARMY.

IN reply to a question by Mr. OTWAY respecting the case of Robert Symes, whose death, according to some newspapers, had been hastened by flogging,

General PEEL said—In consequence of the notice given by the hon. gentleman, I sent to Ireland for information on the facts, and I find that they are as follows:—Private Robert Sim, 74th Regiment, was tried by district court-martial on the 9th of January for an act of gross insubordination in having struck with his fist a sergeant of the regiment, and kicked him on the face when he was knocked down. He was sentenced to 365 days' imprisonment with hard labour (197 of which were remitted), and 50 lashes. The staff surgeon examined the man on three different occasions and pronounced him to be in a good state of health, and fit to undergo corporal punishment; he was flogged on the 14th of January, a staff assistant-surgeon being present at the parade. After punishment he was sent to the cells, where he was allowed bedding, &c., and seen daily by a medical officer. On the 29th of January (14 days afterwards) he was admitted into hospital suffering from fever; his back had nearly healed. On the next day erysipelas of the face and head commenced to set in, and he died on the 9th of February. The post-mortem examination showed that death was occasioned by congestion of the brain consequent on the erysipelas; his back had healed at the time of his death; he had always been a healthy man, but of bad character.

SCOTCH SANITARY LAWS.

Sir R. ANSTRUTHER asked the Secretary of State for the Home Department whether any measure was being prepared by the Lord Advocate for Scotland for the consolidation and application to Scotland of the various Sanitary and Nuisances Acts at present in operation; and whether he was about to bring in any measure for the more economical settlement of disputes arising in carrying out the Poor Law Act.

Mr. WALPOLE replied that there was a Bill in preparation for consolidating and amending the law relating to nuisances in Scotland, and he expected that it would be ready in a fortnight.

IMPORTATION OF CATTLE.

Mr. EYKYN asked the Vice-President of Committee of Council on Education whether any, and, if so, what measures had been adopted to prevent the importation from Holland and Germany of the carcasses of animals infected by the cattle plague.

Mr. CORRY said that the Privy Council were reluctant to prohibit the importation of articles used as food except under the apprehension of serious risk. It appeared to them, as at present advised, that there was no such amount of risk as would justify them in prohibiting importations of cattle.

FEB. 21.

THE METROPOLITAN POOR-LAW BILL.

The second reading of Mr. Hardy's Metropolitan Poor Bill was preceded by a long conversation, in the course of which Lord Enfield expressed a warm approval of the Bill, and indicated several points on which he thought it capable of improvement; and various details were criticized by Mr. Locke, Mr. Alderman Lawrence, Mr. Chambers, Mr. H. Lewis, Mr. Scourfield, Mr. Hibbert, and Mr. Alderman Salomons, in a spirit of general approval.

Mr. VILLERS welcomed the Bill as an opportune advance towards a fairer system of rating and more efficient management of the poor. In vindicating his own administration of the Poor-law Board, he showed that rules and regulations had long since been laid down, which, if attended to by the guardians, would have prevented those cases of neglect and abuse which had recently aroused public in-

dignation. He argued in favour of an extension of the area of rating, showing how unfairly the present charge bore on certain classes of property, but was of opinion that the principle was hardly carried far enough in this Bill. He asked Mr. Hardy to explain why the scarlet-fever, small-pox, and lunatic patients only were to be placed on the general fund, while the other sick were retained on the local funds; and, while approving the establishment of dispensaries as a substantial benefit, he thought it a capricious arrangement to place them on the general fund. He advocated strongly the enlargement of the powers of the Poor-law Board, and that it should be made completely responsible for the proper treatment of the poor.

Mr. HARDY promised to take into consideration the numerous suggestions made, and, in replying in detail to various criticisms, he allowed that the Consolidated Orders of the Board constituted a valuable code for the management of the poor; but pointed out that the Board needed greater power to enforce them, not so much that guardians openly resisted them, but too many were in the habit of defeating them by dilatory and shuffling evasions. In answer to Mr. Villers's objection that the principle of enlarging the area of rating was not carried far enough, he said he had been actuated by practical considerations alone, with a full fore-knowledge that if he had proposed to equalize the rates throughout the whole metropolis, the Bill would have been met by a strenuous opposition, which would have been fatal to it. He intimated that he had in preparation a Bill for the more equitable assessment of the metropolis, which he would introduce if Mr. Hunt's general Bill for that purpose met with a favourable reception.

The Bill was then read a second time.

## MEDICAL OBITUARY NOTICE.

DR. JOHN D. OWENS.

OUR foreign advices record the death of this gentleman in November of last year, and though his name may not be generally known among our medical brethren in this country, yet his position in the colony where his life was spent, the work he performed, and the esteem in which he was held, give him a claim to a notice in our pages. Dr. Owens was an Englishman, and took his diploma from the Royal College of Surgeons in 1839, and his degree of M.D. in 1841. He is mentioned in Taylor's "Medical Jurisprudence," and in the *Surgical and Medical Journal*, for his successful performance of certain difficult operations. In 1850 he arrived in Australia, in charge of emigrants for Sidney and Adelaide, and high encomiums were passed upon him for his skilful attention to the persons under his charge. After a visit to America, he returned again to Australia, and was one of the first who left Forest Creek for Bendigo, where he commenced the practice of his profession. Soon afterwards he went to the Owens gold-fields. At these places he was associated with the diggers, and devoted his energies in every way to promote their interests. This involved him in politics, and brought out his name before the various parties, as well as the authorities of the colony. Being nominated by Sir Charles Hotham, he obtained a seat in the Legislature, where the principles he contended for, and the men whose cause he had espoused, both received recognition through his influence. His attention was frequently diverted from his profession by his political engagements, but he devoted himself to it in various places, and usually obtained a lucrative practice. At length, after different changes in his professional and political life, he turned his attention once more to Bendigo and medicine. For some time he was Officer of Health at the Heads, during the absence in England of Dr. Robertson, and was subsequently appointed Secretary of the Royal Commission on the working of the Publicans' Act, to the duties of which office he devoted his unremitting attention, up to the time of his

death. This took place suddenly. On Monday, the 26th November, he complained of being poorly, and procured some medicine from Mr. Johnson the chemist. In the evening he went home, and his housekeeper provided him with some refreshment, of which he partook apparently in his usual health. A few minutes afterwards he summoned the housekeeper, and directed her to call in Mr. Johnson, which she did. On her return, in about ten minutes, she found that Dr. Owens was no more. An inquest was held, when the jury, in accordance with the medical evidence, returned a verdict of "death from congestive apoplexy." His death is deeply regretted by all who had the pleasure of his acquaintance, and the estimation in which he was held will be seen by the following quotation:—

"Dr. Owen's services were such as could never fade out of the memory of his fellow-citizens, and seclusion never separated him from the social and political movements he had been foremost in originating. Not many were aware of the intellectual energy and cultivation which accompanied a manner so singularly modest and unobtrusive; but his frank, kindly disposition, his sincerity and disinterestedness, were universally acknowledged. Firm, and even fierce enough, when contending against some great public wrong, he never forgot the courtesy of the gentleman in the fervour of the politician; and although prominent in the most exciting debates of our Legislature, we believe he never inflicted a wound upon the feelings of an adversary. There must be something peculiarly loveable in the nature of a man who passes through the turmoil of political life without making personal enemies. This is literally true of Dr. Owens, whose epitaph might fitly be, that he never made an enemy, or alienated a friend."

#### ARMY MEDICAL EXAMINATION PAPERS. CHELSEA HOSPITAL, 1867.

##### ANATOMY AND PHYSIOLOGY.—MR. BUSK.

1. Give the dissection required to expose the genio-hyoglossus muscle, noticing all the parts brought into view, and especially their relations to the muscle; and describe particularly the relations of the sublingual and submaxillary glands, and of their ducts.

2. Describe the muscles of the larynx—their attachments, relations to nerves and vessels, and functions; and give an account of the mechanism of the voice.

3. Describe the position, precise relations, and structure of the duodenum and pancreas, together with their physiological functions.

4. Give the average length in the adult of the following parts, and describe the relations of each:—

- Œsophagus.
- Left bronchus.
- Biliary ducts external to the liver.
- Ureter.
- Vas deferens.

5. What are the immediate and remote effects of the division of a lateral half of the spinal cord in the dorsal region?

##### SURGERY.—MR. PRESCOTT HEWITT.

1. Enumerate the muscles of the forearm which would be paralysed supposing the musculo-spiral nerve to have been cut across on the outer side of the arm just above the supinator radii longus.

2. Up to what period of life can a traumatic separation of the epiphysis occur at the lower end of the femur, and what are the morbid appearances, diagnosis, prognosis, and treatment in such cases?

3. The morbid anatomy, diagnosis, prognosis, and treatment of syphilitic disease of the testicle.

4. The morbid anatomy, diagnosis, and treatment of alveolar abscess.

5. Give a list of the various instruments which might be wanted in an operation for trephining a deep-seated abscess in the head of the tibia, and describe particularly the trephine used in such cases.

##### MEDICINE.—DR. PARKES.

1. Describe the forms of paralysis of motion which arise—
  - From causes within the cranium.
  - From causes within the spinal column.
  - From causes external to the cranium and cord.

2. Enumerate the exanthemata, and give the distinguishing characters of each disease.

3. Give the physical signs of aortic obstruction and aortic regurgitation and obstruction, and state what assistance to diagnosis, if any, is given by the sphygmograph.

4. Give your treatment for the following diseases:—

- Erysipelas of the head and face.
- Whooping-cough.
- Tonsillitis with great swelling.
- Acute eczema of the face in children.

5. What are the normal dimensions of the adult female pelvis? What size would you consider too small for natural delivery of a full-grown child, and what would you do in the case of a woman with a contracted pelvis becoming pregnant?

6. What do you mean by a narcotic? Enumerate the three principal narcotics, and give the chief pharmacopœal preparations of each.

#### LEGAL INTELLIGENCE.

##### COURT OF QUEEN'S BENCH, GUILDHALL—FEB. 18.

(Sittings at Nisi Prius, before the Lord Chief Justice and a Common Jury.)

##### CALTHORPE v. THE GREAT EASTERN RAILWAY COMPANY.

This was an action for a serious injury sustained by a passenger while travelling on the company's line.

Mr. Coleridge, Sir George Honyman, and Mr. Beasley were for the plaintiff; the Solicitor-General (Sir John Karslake), Mr. Serjeant Ballantine, and Mr. Philbrick were for the company.

The plaintiff, Mr. Calthorpe, is a gentleman who farms a large quantity of land in Lincolnshire, on which between £8000 and £9000 is invested, and which he personally managed. He is in his 47th year, is married, and has six children, of whom the eldest is nine or ten years of age. At the time of the accident he was hale, hearty, and athletic, and of active habits. On Saturday, July 1, 1865, he was a passenger on the line from Ely to Lowestoft, and an accident occurred which, it was now admitted (though at first disputed), arose from the negligence of the company's servants, and the result of which was that the carriage was upset, and the passengers thrown violently about. The plaintiff had been attended not only by his own medical man, but by Mr. Erichsen and Dr. Russell Reynolds. The company had appealed to Sir William Fergusson, Mr. Skey, Dr. Bennett, and Mr. Coulson, all of whom had examined him on several occasions, and who were in attendance to-day to give evidence.

Mr. Coleridge, in opening the case, described it as another of those unhappy railway cases which were but too frequent, and one of a peculiarly painful character—a case in which a man in the prime of life, married, and a father of a family, and their sole dependance and support, had been, it was to be feared, utterly destroyed, and unfitted for life for the only occupation with which he was acquainted.

The plaintiff was called as a witness, and had evidently been a very fine man, but it was obvious that he could with difficulty stand or crawl into the box, and his examination was made as short as possible. The material facts are already stated.

After the plaintiff had given his evidence, Mr. Webster, Q.C., who is connected with him by marriage, and the Rev. Mr. Spencer, the vicar of his parish, gave evidence as to his former health and strength, and his present unhappy condition. Mr. Webster said he had known him thirty years, and that he was a man of singular energy and activity, who had entirely, indeed, made himself by his own exertions. He had never known a man of finer *physique*, but he was now "utterly broken down," and could do nothing. The medical men fully supported this view, and said it would be long before he resumed active life.

The Solicitor-General, on the part of the company, said they by no means denied that it was a serious case, and that it had been most truthfully told, but they were led to believe and hope that it might turn out not to be so hopeless as had been represented.

Sir W. Fergusson, Mr. Coulson, and Mr. Skey were called in support of this view, all of them having seen the plaintiff lately. They, however, greatly differed in their opinion. Mr. Coulson feeling certain that the plaintiff would be restored in twelve months; but Sir W. Fergusson doubted whether he would ever entirely be restored.

The Lord Chief Justice, in summing up, said where the medical evidence was so evenly balanced, perhaps it was better to err, if at all, on the side of the party who had sustained the injury. The jury gave a verdict for £7000.

## AN UNQUALIFIED PRACTITIONER.

At Worship-street Police Court, Mr. Edward Lucien Meall, of 33, Pollard's-road, Bethnal-green-road, was summoned at the instance of Dr. Botherton, of Bethnal-green-road, and Mr. Colden, resident medical officer of the Queen Adelaide Dispensary, Bethnal-green, for falsely representing himself to be a legally qualified medical practitioner. Mr. Poland, barrister, prosecuted.

The first witness, Mr. Edward Colden, stated that he is a member of the Royal College of Surgeons of England and resident medical officer of the Queen Adelaide Dispensary, Bethnal-green-road. The defendant resides a few doors from the dispensary, and on the door of his house is a brass plate, bearing the inscription, "Mr. Meall, surgeon and accoucheur." In the autumn of last year the defendant called upon him and asked him if he wanted a *locum tenens*. The witness replied that he did, and asked defendant the remuneration he required. The defendant said 30s. or £2 2s., on which the witness said the terms were so high that he presumed the defendant was a legally qualified practitioner. The defendant said that he was not at present, but he hoped to be, and the witness then said that, not being a registered surgeon, he could not employ him. The duties required were dispensing for three hours in the day.

In cross-examination the witness said that when the defendant called on him he did not represent himself to be a registered practitioner. The witness offered the defendant 25s. a week before he discovered his disqualification, but they parted in consequence of the illegality of defendant's course of proceeding, and not because of the amount of salary.

Elizabeth Short, the keeper of a coffee-house in the Bethnal-green-road, said that, being ill in November last, she was attended by the defendant, who had for some time past frequented her house to see periodicals. She was supplied with medicine, for which she was charged 1s. 6d. per bottle. He saw her about seven or eight times. Her servant usually fetched the medicine from defendant's house, but on one occasion he brought it in his pocket. It was not from seeing the plate on defendant's door she had recourse to his advice. She went to defendant's house once, when he prescribed and gave her medicine. She believed him to be a surgeon.

In cross-examination the witness said she was not aware that the defendant had ever represented himself to be a properly qualified practitioner. She believed he was, as he had attended midwifery cases.

Mrs. Ward, of 2, Gurnett-place, Bethnal-green, said that she went to the defendant's house in the end of January, and asked him why he had not come the night before to see her husband when she sent her daughter to him. The defendant asked her what was the matter, and she told him that her husband was in a consumption. The defendant said, "What's the use of attending for consumption?" and then asked for a guinea as his attendance fee. She said she could not afford it. He then said that he attended some free of charge when recommended by the clergyman. He told her to go to Dr. Jarvis, who would attend her husband for 1s. or 1s. 6d. She had been recommended to the defendant by Mr. Colden.

In cross-examination the witness said she applied to the defendant as a last resource, as her husband was very ill. She was not told by Mr. Colden that it was a trap.

Mr. Edward Trimmer, Secretary to the Royal College of Surgeons, was called to prove that the defendant was not a member of the college, and therefore not legally qualified. The defendant contended that having practised as a surgeon before the passing of the Medical Registration Act, he did not come within the meaning of the Statute. He had been employed by medical men, and had invariably acquitted himself to their satisfaction.

Mr. Newton said that he regarded the case as proved, but, as there was no evidence to show that the defendant had made money by it, the penalty would be mitigated to £5 and costs.

The defendant was understood to say that he should appeal against the magistrate's decision.

**ALLEGED DEATH OF A BUTCHER FROM CATTLE PLAGUE.**—A butcher of Liege has just died in consequence of a casual inoculation of the virus of the cattle disease. He had been engaged in slaughtering the infected animals at Hasselet, and in cutting up a carcase had accidentally scratched his hand, which swelled up with such rapidity as to render medical aid of no avail.

## Medical News.

**COLLEGE OF SURGEONS OF ENGLAND.**—A special meeting of the Council of the College of Surgeons was summoned on Thursday last to consider a motion to the effect that Mr. South, and Mr. Luke should cease to be members of the Examining Board. The motion was proposed by Mr. Charles Hawkins, and seconded by Sir William Fergusson; but in a full meeting of twenty-four members, only six were in favour of thus carrying into effect the charter of the College. The motion was of course lost.

**THE PREVENTION OF INFANTICIDE.**—Mr. Walpole's Bill for amending the law relating to murder contains fourteen clauses, of which six are devoted to the protection of new-born children. Wilful injury to a child during its birth or within seven days thereafter becomes, under the Bill, a felony punishable with penal servitude for any term not exceeding ten nor less than five years, or with imprisonment for any term not exceeding two years, with or without hard labour or solitary confinement. Proof that the child was completely born alive is dispensed with. The deliberate murder of a child remains a capital offence; but it is open to a jury to acquit a person of the murder of a child, and to return a verdict of "guilty of wilful injury," which carries the punishment of penal servitude or imprisonment. The proviso contained in the Act 24 and 25 Vict., c. 100, s. 60, authorising juries, on an indictment for the murder of a child, to find the accused guilty of the offence of endeavouring to conceal the birth of the child, is repealed by the Bill.

**THE PHARMACY ACT.**—A deputation from the chemists and druggists, not members of the Pharmaceutical Society, lately waited upon the Council of the latter body to endeavour to arrange the heads of a plan for the future extension of the Pharmacy Act of 1852, and to express the views of the trade at a meeting which was held some time since, to consider certain suggestions forwarded by the Pharmaceutical Society to the Home Office: the object really being to compel all persons—who may hereafter assume the title of chemist and druggist, or keep open shop for dispensing physicians' and surgeons' prescriptions, or vending, dispensing, or compounding certain dangerous drugs to be enumerated in a schedule—to undergo an examination and obtain a certificate of qualification. There was no difference of opinion between the Society and those who are not members of it on this, the main point of the suggestions, but there was a difference as to the future constitution of the Council of the Pharmaceutical Society. Chemists and druggists in business at the time of the passing of the proposed Bill will be left entirely unaffected, but it would be provided that a voluntary registration as chemists and druggists should be open to them, and that those who availed themselves thereof should be eligible for admission to membership of the Pharmaceutical Society. It was originally proposed in the suggestions that the Council should consist entirely of pharmaceutical chemists, but on Tuesday it was arranged that chemists and druggists, being members as above described, should also be eligible for the Council. The Council, however, was not to contain more than a certain proportion of such members agreed upon.

**THE ATLANTIC CABLE.**—The calculation of the longitude between England and America has, hitherto, depended upon the chronometric expeditions instituted by the Coast Survey during the years of 1849-51 and 1855. Fifty chronometers were transported three times in each direction across the Atlantic. The probable error of the result of these expeditions was 19-100ths of a second. The value thus obtained, though for all practical purposes sufficiently precise, is not so for the necessities of astronomical science in its present refined state. When, therefore, the success of the cable provided telegraphic Transatlantic connexion with England, parties of the Coast Survey were formed, under the direction of Dr. B. A. Gould, to take advantage of this means of obtaining a value more precise than that furnished by the chronometric expeditions, allusion to which has been made. The peculiarities in the methods and apparatus employed in working the cable render the process of determining the longitude by its means different in many respects from that by the land telegraph lines. New obstacles, which made success exceedingly doubtful, were to be surmounted, and new sources of error eliminated; but, thanks to the genius, experience and perseverance

of Dr. Gould, these have been overcome, and results of remarkable precision elicited. The probable error of the resulting longitude is about four hundredths of a second. Perhaps it will give the reader a clearer idea of the nicety implied in this by stating that a distance of about 1900 miles has been measured, and that the measure is not probably more than 40 feet from the truth. The time required for a signal to pass through the cable has been discovered with a still greater precision to be 31-100ths of a second, which is probably not in error by one hundredth of a second. This is equivalent to a velocity of 6020 miles a second, and is notably less than the velocity of the electric fluid upon land lines, which numerous observations have shown to average 16,000 miles a second.—*Boston Transcript.*

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

*The Professorship of Botany at the Royal College of Surgeons of Ireland.*—In our observations on this subject last week we inadvertently omitted to mention that Dr. Minchin had distinguished himself as a prizeman in Botany.

*Assumption of Medical Titles.*—A Correspondent calls our attention to addresses, which appear in the *Cork Examiner* for the 18th inst., from two gentlemen, candidates for the office of Physician to the Fever Hospital. One of these gentlemen signs himself M.D., &c., &c., although he does not appear in either the "Medical Register" or the "Directory" at all. This gentleman, on a former occasion, signed himself a Licentiate of the Royal College of Physicians of Edinburgh and an Apothecary, and we are not aware that he has since obtained any further qualification. If so, the appropriation of the letters M.D. are a most unwarrantable assumption of a dignity to which there exists no right whatever, and should, as we think, furnish a very conclusive argument in favour of the candidate who really possesses the qualifications which he appends to his name.

### MEDICAL APPOINTMENTS.

- BEIGEL, H., M.D., has been elected Honorary Physician to the Faringdon Dispensary.
- COLEMAN, A., M.R.C.S.E., Lecturer on Dental Surgery at St. Bartholomew's Hospital, has been appointed Dental Surgeon to the Hospital, vice S. J. Tracy, M.R.C.S.E., resigned.
- COOPER, H., M.R.C.S.E., has been appointed Medical Officer for District No. 1 of the Cricklade and Wootton Bassett Union, Wilts, vice G. V. Cooper, M.R.C.S.E., resigned.
- DANDY, T., M.R.C.S.E., has been appointed Medical Officer for District No. 4 of the Ormskirk Union, Lancashire, vice C. Dandy, M.R.C.S.E., deceased.
- FURNIVAL, C. H., L.S.A.L., has been appointed Resident House-Physician to the Westminster Hospital, vice C. F. Oxley, M.R.C.S.E., whose appointment has expired.
- HARBER, W. M., M.R.C.P.Ed., has been appointed Medical Officer for the Hurst-Green District of the Ticehurst Union, Sussex.
- HASLEWOOD, J. A., M.R.C.S.E., has been appointed Medical Officer for the Barton District of the Darlington Union, Durham, vice W. Haslewood, M.D., deceased.
- HISLOP, G. B., L.F.P. & S. Glas., has been appointed Medical Officer for the Longbenton District of the Tynemouth Union, Northumberland, vice F. W. Wilson, M.R.C.S.E.
- JONES, R. A., M.R.C.S.E., has been appointed Surgeon to the County Gaol of Carnarvon, vice R. Jones, M.R.C.S.E., deceased.
- M'CARTHY, J., L.R.C.P.Ed., has been appointed Resident Medical and Surgical Assistant at St. Mary's Hospital, Manchester.
- MEYRICK, Ed. W. W., has been appointed Junior House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.
- NEAL, Dr. JAMES, has been elected Honorary Surgeon to the Birmingham Lyng-in Hospital.
- PATERSON, GEORGE, K.H., L.R.C.P.E. (Exam.), L.R.C.S.E., Assistant-Surgeon, has been appointed Surgeon 1st Administrative Battalion of Perthshire Rifle Volunteers.
- POPE, R. H., L.R.C.P.Ed., has been appointed Medical Officer to the Workhouse and Fever Hospital of the Donegal Union, and Medical Officer and Public Vaccinator for the Donegal Dispensary District of the same Union, vice J. M'Crae, M.D., resigned.
- SARGENT, G. P., M.D., has been appointed Medical Officer for the Wickford District of the Bilericay Union, Essex, and for District No. 5 of the Chelmsford Union, vice W. L. Le Sage, M.R.C.S.E., resigned.
- SIDDALL, G. O., M.R.C.S.E., has been appointed Medical Officer for the Alfreton District of the Belper Union, Derbyshire, vice Spencer, deceased.

THOMASON, R., M.R.C.S.E., has been appointed Visiting Surgeon to the Hereford General Infirmary, vice T. Cam, F.R.C.S.E., resigned.

TRIMMER, F., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for District No. 1 and the Workhouse of the Okehampton Union, vice Thos. Gambier, M.R.C.S.E., resigned.

### MEDICAL DIARY OF THE WEEK.

WEDNESDAY FEB. 27.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Gulstonian Lectures: Dr Southey, "On the Nature and Affinities of Tubercle."

HUNTERIAN SOCIETY.—7½ P.M. Council.—8 P.M. Dr. Braxton Hicks, "On the Treatment of Cicatrices of the Vagina, with Remarks."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE. 8 P.M.

THURSDAY, FEB. 28.

ROYAL INSTITUTION.—3 P.M. Professor Tyndall, "On Vibratory Motion and Sound."

FRIDAY, MARCH 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Professor Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Gulstonian Lectures: Dr Southey, "On the Nature and Affinities of Tubercle."

ROYAL INSTITUTION.—8 A.M. Captain V. D. Majendie, "On Breech-loading Small Arms."

SATURDAY, MARCH 2.

ROYAL INSTITUTION.—3 P.M. G. A. Macfarren, Esq., "On Harmony."

### BOOKS, &c., RECEIVED.

A Practical Treatise on Anæsthesia. By Drs. Pirrie and Keith.  
The Story of the Truck. By W. Reid.  
Observations on the Comparative Advantages of affording Obstetric Attendance on Poor Women in Lying-in Hospitals, and in their own Homes. By D. Phelan, M.R.C.S.  
Observations on the Pulse of Typhus. By T. W. Grimshaw.  
Physiological Remarks upon the Causes of Consumption. By Valentine Dukz, M.D.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

- SMITH.—On the 20th inst., at 10, Pump-street, Londonderry, the wife of Edward Smith, M.B.T.C.D., of a son.
- SMITH.—On the 23d inst., at Lifford, Co. Donegal, the wife of Charles Smith, M.D., of a son.
- GRIFFITH.—On the 9th inst., the wife of S. C. Griffith, M.D., Wimpole-street, Cavendish-square, of a son.
- EVANS.—On the 11th inst., at Cheshunt, Herts, the wife of N. Evans, M.D., of a son.
- GOODING.—On the 11th inst., at Cheltenham, the wife of J. C. Gooding, M.D., of a daughter.
- COATES.—On the 12th inst., at Chapel-street, Devonport, the wife of Matthew Coates, M.R.C.S.E., Assistant-Surgeon H.M.'s Ship "Caledonia," of a daughter.
- UBE.—On the 13th inst., at the Minister-yard, York, the wife of John Ure, M.D., of a son.
- EAMES.—On the 14th inst., at Plymouth, the wife of Dr Eames, H.M.'s Ship "Gladiator," of a daughter.
- FERGUSON.—On the 17th inst., at Ailsa Cottage, Girvan, Ayrshire, the wife of Alexander Fergusson, L.R.C.P.Ed., of a son.
- FOTHERBY.—On the 19th inst., at Trinity-square, Tower, the wife of Henry J. Fotherby, M.B., of a daughter.

### MARRIAGES.

- GANGE—WHITECHURCH.—On the 12th inst., at Hariton, Cambridge-shire, F. A. Gange, M.D., of Faversham, Kent, to Susan, daughter of W. Whitechurch, Esq.
- METCALFE—GARDINER.—On the 14th inst., at Bishop's Lydeard, Somerset, Fenwick Metcalfe, Esq., son of Charles Metcalfe, Esq., of Inglethorpe Hall, Emeth, Norfolk, to Augusta Katharine, third daughter of the late Henry Gardiner, Esq., Madras Civil Service.
- FAWSETT—BOUCHER.—On the 14th inst. Fulbourn, Frederick Fawsett M.D., of Wisbech, to Ellen Eliza, daughter of the late C. Boucher Esq., of Wisbech.

### DEATHS.

- JONES.—On the 20th inst., suddenly, at the residence of his father Stone House, Wellington, Salop, Dr. Edward P. Jones, L.R.C.P., late of Waterloo, near Liverpool, aged 28.
- MARTIN.—On the 12th inst., T. Martin, F.R.C.S.E., of Reigate, Surrey, aged 87.
- DAY.—On the 14th inst., H.G. Day, M.R.C.S.E., of Isleworth, aged 58.
- POWELL.—On the 14th inst., D. Powell, M.R.C.S.E., of Anwell-street, Pentonville, aged 63.
- DYER.—On the 14th inst., Thos. Dyer, M.D., of Forest-hill, Medical Officer to the London, Brighton, and South Coast Railway Company, aged 57.
- BARLOW.—On the 20th inst., at Shakespeare-street, Chorlton-on-Medlock, Manchester, after a long and painful illness, Joshua Barlow M.D., aged 47.

Oration.

THE ANNUAL ORATION FOR 1867,

DELIVERED AT THE

HUNTERIAN SOCIETY,

HELD AT THE LONDON INSTITUTION.

By WILLIAM SEDGWICK SAUNDERS, M.D.,

CONSULTING-PHYSICIAN TO THE SCINDE AND DELHI, EAST INDIAN, BOMBAY AND BARODA, GREAT SOUTHERN OF INDIA AND CALCUTTA, AND SOUTH-EASTERN RAILWAY COMPANIES; VICE-PRESIDENT HUNTERIAN SOCIETY; TREASURER TO NEW SPYENHAM SOCIETY; MEDICAL EXAMINER TO MUTUAL LIFE OFFICE, ETC., ETC.

MR. PRESIDENT, I purpose to devote the time, which your indulgence has placed at my disposal this evening, to laying before you the results of some inquiries into the origin and history of medicine, and the medical profession; regarding the subject rather from a *social* than a *scientific* point of view.

My scheme will introduce you to some of your old acquaintances; not for instruction, but to remind you of those passages in their lives which may have been pressed out of your memories by the sterner realities of professional duties.

An inquiry into the origin of medicine must begin with the history of *man* himself, since *pain* and *death* are the inevitable conditions of his existence, and the desire to mitigate the *former*, and *postpone* the triumphs of the *latter* arose *from*, and has kept pace *with*, the development of the various diseases to which time and circumstances have subjected him. The *primal man*, we know, was created pure and innocent, free from liability to pain, and possessed of unmixed capacity for the enjoyment of the pleasures that surrounded him; glowing with health, and with every emotion redolent of new delight. At sight of him,

Each hill gave sign of gratulation,  
Joyous the birds; fresh gales and gentle airs  
Whispered the woods; and from their wings  
Flung rose, flung odours from the spicy shrubs:—

Apprehension of the miseries to which his progeny were doomed, would have *marred* this happiness; hence his ignorance of evil, and his belief that the felicity he enjoyed would be as *permanent* as it was *perfect*. But our business is with man in his *actual* condition; the sport

"Of ghastly spasm, and raking torture qualms  
Of heart-sick agony—of moping melancholy,  
And moon-struck madness."

Undertaking to examine the subject *ab initio*, we must take into account the *sources* of our information, and as our knowledge of every event *antecedent* to the *discovery* of *writing* must have been transmitted by oral or traditional agencies, we have to settle, in some degree, how far such evidence is worthy of credence.

According to popular belief, the Noahic flood destroyed the whole human race, with the exception of *Noah* and his family; who were therefore the sole depositories of the traditions of the events which had occurred between the time of *Adam* and themselves. The great longevity of these antediluvian fathers made this oral transmission easy; and we know, that the sons of *Noah* lived to see the birth of *Abraham*, whom, as the founder of circumcision, we claim as the first operative surgeon on record.

In dealing with dates, I adopt the commonly accepted chronology, unmoved by those refined speculations so much in favour at this time.

I begin with *Moses*, for whatever evidence may be urged upon us in the shape of marbles, or monument, claiming an antiquity anterior to the advent of the Jewish law-giver, it is a positive and unimpeachable fact, that no *writings* are in existence, which in point of age reach within many centuries of the Pentateuch; indeed, as we shall presently see, the oldest of the Greek writers are, in comparison with *Moses*, but as the children of yesterday.

The five books of *Moses* were written 1500 years before *Christ*. *Hesiod*, the father of Greek literature, flourished

500 years later; and *Homer*, the next in succession, nearly a century after *Hesiod*.

*Herodotus* places *Homer* 400 years before himself; thus bringing the "father of history," as he is termed by *Cicero*, to about 500 years before the advent of our Saviour, so that the difference between the author of the Pentateuch and the oldest Greek historian cannot be much less than 1000 years.

I pass over the pretended antiquity of the Chinese and *Parsis* records: these have been disposed of very satisfactorily, and however much *fancy* may dwell upon the losses to literature inflicted by the Caliph *Omar*, when he destroyed the Alexandrian library, in the year 640, a very little reflection will convince us that as these treasures, real or assumed, had been ransacked for ages, by the brightest spirits of *Greece* and *Rome*, everything worthy of note has been handed down to us.

The *learned* talk about the writings of the Assyrians, the Babylonians, and the Egyptians; but they do not produce a single scrap of tangible evidence in support of these pretensions.

It may, however, be contended, that although there are no *writings* extant, *traditional* evidence is very strong; and this establishes a high antiquity for *Lycurgus*, who lived 900 years before the Christian era. The more, therefore, we inquire, the stronger the proof becomes, that *Moses* as a lawgiver flourished 600 years before the highest claimant to our veneration on the grounds of primitiveness; and thus we are entitled to assume that the Greek legislator took much that is excellent, in the laws ascribed to him, from his Jewish predecessor.

*Lycurgus* lived about the time that *Shishak*, king of *Egypt*, destroyed the temple of *Solomon*, and carried away many captives: it is therefore no very extravagant supposition, that the pentateuch of *Moses* was *known* to the great lawgiver. During the peaceful reign of king *Solomon*, the intercourse between the Jews and the Egyptians was frequent and extensive, the great monarch needing the assistance of skilful artificers for the construction of the "Temple of Jerusalem," broke down that barrier of exclusiveness that had previously isolated his people.

Now the *learned* of that day were seekers after wisdom wherever it was to be found; and moreover, as the fame of *Solomon* was coextensive with the then existing world, so acute an observer as the *founder* of the Grecian law could not fail to use the materials which the wide spread knowledge of the Jewish king's sayings and doings had placed within his reach.

Every Jew was required to read the law, or *hear it read*, once a year—each individual therefore became a *living depository* of its truths, and, consequently, a competent *teacher* of those who might desire to be instructed in such matters.

*Moses* then comes before us as the first *writer*, and the first *lawgiver*; and we shall now proceed to show that to these, he added the still *greater* distinction of being the first *physician*, and promulgator of sanitary precautions.

At present, however, I will not further intrude upon your patience, but leaving his claims where I have placed them, pass on to the consideration of the character of the laws themselves;—and here we arrive at a body of enactments so excellent, so well adapted, not only to the requirements of a nomadic and pastoral people wandering in a wild country, but to that *same* people when they subsequently became dwellers in cities, and suffered all the encumbrances of a more advanced civilization, that our admiration is unbounded. *Moses* made laws for all times and for all communities, *general* as well as *particular*, reaching the *nation* through every individual member thereof; his rules for the preservation of health embraced the consideration of personal cleanliness enforced as a *religious* obligation in order that he might thereby enlist the unvarying co-operation of the priesthood.

In a climate incentive to animal enjoyments he placed strict barriers for the preservation of *chastity*, and decreed that matters relating to sexual intercourse should be under the surveillance of the priest; directions were also given

to the *menstruous* woman, and for her conduct during pregnancy and in *childbed*. The ordinance of circumcision was devised not alone for ablutionary purposes, but for other well understood objects conducive to purity. Further, it was directed how the man should order himself in affections of the virile organs; and more emphatically, what he was bound to observe when the terrible *leprosy* afflicted him. In such a calamity he was compelled to withdraw from his house, to be separated from society, and present himself to the priest at various periods during the progress of the disease; also to remain in a cheerless exclusion, where, if by chance, any unwary passenger came in sight, he was commanded to cry aloud, *unclean! unclean!* When convalescence and health returned, the priest pronounced him cured of his leprosy, and he was then permitted to return to his home; but if the leprosy was supposed to cling to the habitation, that, too, was subjected to isolation, and in some instances to total destruction.

The same precautions obtain in our own times, although nearly 3400 years have elapsed since they were first insisted upon by Moses.

Thus, we are told by Dr. Thompson, an eminent American writer on the "Holy Land" (where he resided many years), that lepers are everywhere regarded as unclean at Jerusalem (where there is always a considerable number of them), and in which place a separate quarter is assigned to them, to which they are rigidly confined. Dr. Thompson says: "I have seen them cast out of the villages where they resided, and no healthy person would touch them, eat with them, or use any of their clothes or utensils, and even the Arab tent dwellers cast them out of camp. The leper beggars stand apart, and never attempt to touch you, even as it was in the time of the Saviour, 'when the ten lepers stood afar off and lifted up their voice of entreaty.'"

The same writer furnishes us with the following graphic description, which, as coming from an eye witness, we have deemed worthy of notice:—

"Sauntering down the Jaffa road, on my way to the Holy City, I was startled by the sudden apparition of a crowd of beggars, *sans eyes, sans nose, sans hair, sans everything*; they held up their *handless arms*, unearthly sounds gurgled through throats *without palates*, and, in a word, I stood horrified, when, for the first time, I found myself *face to face* with a leper." He then goes on to say: "For many years I have sought to get at the mystery of its origin, but neither books nor learned physicians have thrown any light upon it. I have suspected that this remorseless enemy originates in some self-propagating animalcule, and thus I can conceive the *possibility* of the contagion reaching the walls of a dwelling. No one has spoken with *authority*, as to what it *proceeds* from or how it is generated.

"New born babes of leprous parents are often as pretty and healthy in appearance as other children, but the '*scab*' comes on by degrees, the hair falls off, joint after joint of the fingers and toes shrink up, the gums are absorbed, and the teeth fall out and disappear; the nose, the eyes, the palate are slowly consumed, and finally the wretched victim sinks into the earth under a disease beyond the control of medicine, which cannot even mitigate its tortures.

"To my mind there is no conceivable manifestation of Divine power more triumphantly confirmatory of Christ's divinity than the cleansing of a leper with a word."\*

\* The contagiousness of Leprosy was held in universal belief up to the seventeenth century, when certain writers on the subject began to question the validity of a doctrine which had been handed down to them through successive ages, by all the early observers of the Jewish, Egyptian, Arabian, Grecian, and Hindoo countries, and the view then advanced has been confirmed by the report of the Committee recently appointed by the College of Physicians, who states that:—"The all but unanimous conviction of the most experienced observers in different parts of the world, is quite opposed to the belief that leprosy is contagious or communicable by proximity or contact."

On the other hand we have to consider the testimony afforded us by the shrewd and intelligent teachers of ancient times. Thus, Aræteus believed it to be as contagious as the *plague*, and like it communicable by respiration; and *Etius*, following *Archigenes*, thought that "the air became contaminated through the effluvia of the sores." *Avicenna* believed leprosy to be contagious in the general sense of that term.

The initiatory rite of circumcision was, by Divine command, first performed by Abraham in the year of the world, 2107 or about 1897 years before Christ:—At the age of 99 years, Abraham, together with his son Ishmael and all his dependents were circumcised.

Ishmael at this time was thirteen years old, and, as we are informed by Josephus, was the founder of the Arabian nation, who to this day do not circumcise until after the thirteenth year.

Isaac, the child of promise, the heir who was to carry on the race of the patriarch, was circumcised on the eighth day after his birth, and this, among the Hebrews, became a law, and a statute for ever.

One of the tapestries at Hampton Court, in the time of "Holbein," represents the operation being performed upon Isaac, with what appears to be a knife made of stone, which was the instrument used for many ages for this purpose.

By the kindness of my friend, the Rev. William Sparrow Simpson, the learned Librarian and Minor Canon of Saint Paul's Cathedral, I am enabled to show you some of these knives of stone; and further evidence of the employment of such implements will be found in Exodus 4th chapter and 25th verse, where it is written—"Then Zipporah took a sharp stone and cut off the foreskin of her son and cast it at his (Moses) feet."\*

Some writers believe that the practice of circumcision existed for ages amongst the Heathens before the time of Abraham, whilst others have not hesitated to date its origin as far back as our first father, asserting that Adam was taught by the angel Gabriel to satisfy an oath he had made to cut off that flesh, which after his fall had rebelled against his spirit.

Much has been written with regard to the comparative antiquity of this custom among the Egyptians and Ethiopians; a point upon which the erudite Herodotus leaves us in doubt.

Circumcision of both sexes exists amongst the Abyssinians, Nubians, Egyptians (both ancient and modern), Hottentots, and probably many other nations. But in Turkey, Persia, and in the South Sea Islands, and those of the Indian Seas, the practice is confined to the male sex. The Mohammedans adopt the rite of circumcision, and Mahomet himself was circumcised, although no mention is made of the fact in the "Koran."

Doubtless, the so-called circumcision of women, as it is practised in some countries, is a modification of what we understand by the term, and involves structures other than the clitoris or nymphæ; and it is equally true that the custom is adopted by many races totally irrespective of any religious significance.

Sonnini de Manoncourt, a distinguished traveller and naturalist of the eighteenth century "having examined a young girl of Egyptian origin, about eight years old, found a thick, flabby, and fleshy excrescence, covered with skin, which grew above the commissure of the labia, and hung down half an inch, resembling in size and shape the caruncle pendent from the bill of a turkey cock."

Conditions of a similar nature are said to exist among the women of the interior of Africa, and are probably due to climatic influences, but the more common forms of disease are those of simple hypertrophy of the external parts

*Avenscar* by contact; *Italy Abbas* and *Aisaharavius* through the respiration; and *Rogerius* "per coitum."

[These interesting facts are taken from an able article in the *Lancet*, February 9, 1867.]

\* *Pliny* tells us that the priests of *Cybele*, the mother of the gods had sharp stones with which they cut themselves in their extacies. *Calutus* says, that *Atys* demasculated himself with such an instrument.

The Rabbinical law stands thus: we may circumcise with anything, even with a flint, with crystal (glass) or with anything that cuts, except with the sharp edge of a reed, because the enchanters make use of that, or it may bring on a disease." Again we have the evidence of *Leutholf* that the Ethiopians used stone knives for circumcision in his time 1581. Speaking of the *Alnajah*, an Ethiopian race, he says:—"Alnajah gens æthiopum cultris lapideis circumcisonem peragit"

Mr. E. B. Tylor in his "Researches into the Early History of Man-kind," has suggested as the probable reason why stone was used as a cutting instrument, that it was less likely to cause inflammation than either bronze or iron. And *Pliny* states that the mutilation of the priests of *Cybele* was done with a sherd of Samian ware to avoid the same danger.

of generation ; and it is not unreasonable to suppose that the surgical interference necessary for their removal has given rise to the general term of circumcision.

"Simple excision of the clitoris has been practised for very many centuries by certain nations," and I purpose quoting some interesting observations just published by Dr. T. H. Tanner, upon the subject. His first extract is from Strabo, the geographer, A.D. 21, who, in speaking of the Egyptians, says :—"They *circumcise* the males and *excise* the females, as is the custom also among the Jews, who are of Egyptian extraction." The custom appears to have been continued down to our own day, and Mr. W. G. Brown,\* who resided for some time at Darfour, North Africa, writing in 1779, thus alludes to it :—"The excision of females is a peculiarity with which the northern nations are less familiar ; yet it would appear that this usage is more evidently founded on *physical* causes, and is more clearly a matter of *convenience*, than the circumcision of males, as it *seems not* to have been ordained by the precept of any inspired writer."

"This excision is termed in Arabic '*chafadh*.' It consists of cutting off the clitoris a little before the period of puberty, or at about the age of *eight or nine* years."

Again, the Nubian traveller† *Burckhardt* tells us—"The daughters of the Arabs *Ababde*, and *Djaafere*, who are of Arabian origin, and inhabit the western bank of the Nile from Thebes, as high as the cataracts, and generally those of all the people to the south of *Kenne* and *Esne* (as far as *Sennaar*) undergo circumcision, or rather *excision* (excisio-clitoridis), at the age of from *three to six* years: Girls thus treated are called *mukhaeyt*."

But perhaps the most reliable account of the circumcision of females in Western Africa is that given by the late Mr. W. F. Daniel, who was a distinguished member of our own profession.

"Mr. Daniel tells us that the excisive process in Western Africa is variously performed in accordance with the usages of the different districts where it is resorted to. The operation consists either of"—

"1. Simple excision of the clitoris ; 2. excision of the nymphæ ; 3. excision of both nymphæ and clitoris ; 4. excision of a portion of the labia pudendi, with either or all of the preceding structures."

"The history of the operation is involved in obscurity, that it was secretly inculcated as one of those gloomy rites which the female proselyte had to undergo, as a preliminary measure, prior to her initiation into those dread mythological creeds, which, in Egypt and the adjoining countries were swathed in the folds of an allegorical and almost impenetrable mysticism, is the most likely inference." *Eventually* the progressive decay of the religious institutions, gradually led to its promulgation and practice among the masses of the people, for the *priests* who, independent of their scientific attainments, were also well versed in medicine, might have advocated its use both in a moral and hygienic point of view, as conducive to the welfare of the female population.

I have been led into this digression by reflecting over the barbarous and unphilosophical meddling of certain practitioners of our metropolis who are in effect, degrading our practice of surgery to the level of that of the savages we have just described, without possessing the same claim to our consideration on the score of ignorance, barbarism, and superstition. The modern antic Yeclet "*clitoridec-tomy*" (to which I refer), is, as the "*Lancet*" says, "a proceeding which, if it be *useless*, is a *lamentable mistake*, and if it be *unnecessary*, a *cruel outrage*."

The next proposition we may fairly look for will be to imitate still further the customs of these Western Africans who, in certain tribes, whenever a girl shows any very strong indication of sexual feeling (before she is betrothed), at once proceed to produce an obliteration of her vagina by the intense inflammatory action set up by the forcible in-

troduction of a mass of the "*capsicum frutescens*," or bird pepper—to my mind not one shade more inhuman or barbarous than unsexing a woman for ever, upon an assumption which grossly libels our female population.

The position taken by the early Christians in reference to the practice of circumcision was decidedly antagonistic, so far as any *value*, in a *religious* point of view, should be ascribed to it ; nevertheless, their apostles and teachers permitted it to continue, at the discretion or inclination of those who chose to submit to it.

It is an interesting fact to note that the Copts, whose christianity dates back from the persecution of Diocletian (called the era of martyrs) in 303, and the Abyssinian Christians, who also reckon from the fourth century, adopt the custom to this day, from a belief that it gives them a further chance of entering Paradise, beyond the baptism they receive as Christians. It is also singular that these sects accept several other doctrines and precepts of the Mohammedans and Jews, among whom they dwell.

The precise mode of operating upon males varies in different countries. In Madagascar three separate and distinct operations are inflicted upon the individual. In the South Sea Islands the natives simply slit up the prepuce on its dorsal aspect, and in earlier times the practice was to cut the prepuce all around the corona, avoiding the frenum. In the Fiji Islands the instrument used is a sharp splinter of bamboo.

Upon females, the process of excision is performed by aged women. In Egypt the custom is still maintained ; and the women of the *Said* travel about from town to village, crying out "Circumcisor ! who wants a circumcisor ?" In Old Calabar Mr. Daniel had the opportunity of witnessing the operation, which is likewise performed *there* by aged females. The girl having been placed on the knees of a woman, with the legs apart, the clitoris was seized, *forceps-like*, by two pieces of bamboo or palm-sticks, and being gently drawn forth, was severed with a sharp razor.

Among the Jews this peculiar and distinctive mark is perpetuated in our days, and without any material change of ceremonial. The mode is as follows :—The godfather being seated, takes the child on his knees, and the operator (who may be the father of the child, if capable, or some friend of the family, or a professed expert) takes up with his fingers, or a pair of tweezers, as much of the prepuce as he intends to cut off, and, on applying the knife, says—"Blessed be Thou, O God, who has commanded us to use circumcision." He then sucks the blood, and spits it into a cup of wine, and having applied styptics to the wound, retakes the cup, and having blessed *it* and the child, pronounces the name of the child, and moistens his lips with the contents of the cup. Various prayers are then said, and the ceremony is concluded.

Though the modern Jews generally use a steel instrument, there is this remarkable exception—that, when a male child dies before the eighth day, it is circumcised prior to burial, but this is done, not with the ordinary instrument, but with a fragment of glass or flint.

The practice extended to the Ishmaelites, and, as we have already stated, was subsequently adopted by Mahomet, so that a very large section of the human race are to this day participators of a rite established considerably more than 3000 years ago.

The subject cannot be dismissed without noticing the fact that the Jews under their various captivities, subjugations, and persecutions, endeavoured, in some instances, to obliterate the marks of circumcision. This is abundantly proved, not only by contemporary writers, but by the evidence of Epiphanius, Celsus, Gelen, Paulus Ægineta, Fallopius, and others, who have enlarged upon the *modus operandi* for the accomplishment of this object. It is, further, a noteworthy circumstance that the Jews *entirely* suspended the practice of circumcision during the forty years of their wanderings in the wilderness.

In contemplating the sufferings of this unfortunate race, the heart sickens at the punishments which resulted from their resistance to foreign usurpation. Unable to discern the hand of God in their humiliation, their struggles were,

\* Travels in Africa, Egypt, and Syria, from the year 1792 to 1798, p. 847. London, 1799.

† Travels in Nubia, by the late John Lewis Burckhardt, p. 332, London, 1819.

indeed, hopeless, but not the less heroic. Captives in Babylon, after a long and cruel servitude they were restored only to be again scattered by the destruction of Jerusalem, under Titus. Through the varying fortunes of the Romans, no resting-place seems to have been vouchsafed to them; plundered and disgraced, the fall of Rome only eventuated, as far as they were concerned, in a change of masters. Ruthless persecutors tracked them through the dark ages, and what Heathenism spared, Christianity despoiled; our pious ancestors praising God when they had a chance of maltreating an Israelite.

For these reasons, and with such incentives, can we doubt that the timid amongst them would endeavour to remove the tangible means of identity which circumcision afforded.

We have so refined away the simplicity of the patriarchal times, that it is almost necessary to apologise for alluding to the reverential awe with which all matters relating to the seed of Abraham were regarded. It was a solemn and impressive act when the Patriarch, believing that the time was come for his son Isaac to have a wife, sent for his chief servant, and said, "Put, I pray thee, thy hand under my thigh, and swear by the Lord that thou wilt choose a wife for my son out of mine own kindred;" and the servant, with his hand on his master's genitals, takes the required oath; and we all know how faithfully he performed it. Whilst this simple but deeply significant ceremony was being enacted, the heart of the father of the faithful was doubtless filled with contemplations of the great purposes for the accomplishment of which the organs of generation were appropriately considered as the direct agents.

This mode of taking the oath is further adverted to in the 47th chapter of Genesis, when Jacob is taking his farewell of his children.

In our blind adoration of classical heathenism we undervalue the sublime and not less poetical incidents which mark the rise, progress, culmination, and decay of that people, with whom our highest interests are identified. If, for instance, the Book of Job had not been written under inspiration, and had been accidentally discovered among the ruins of the first Babylon, our antiquarians would have regarded it as the loftiest of epics; and especially so if, instead of inculcating the worship of the true God, its subject had been in glorification of whatever false deity might have been in the ascendancy when this most ancient poem was composed.

The prejudices of education subjugate the judgment, and the gross and sensual attributes with which the Greek poets invested their deities are accepted with complacency, if not with admiration; even Pope, their great panygerist, describes their heroes thus:—

"Gods, partial, changeful, profligate, unjust,  
Whose attributes were rage, revenge, and lust."

This, of course, will be set down for rank blasphemy against the canons of taste. We are exuberant in our praises of the genius of Homer, and not to worship his inventive powers is an offence of the deepest dye; but when we are barbarous enough to critically examine this wonderful mythology, and to determine the claims to applause—say of supreme Jove—we are rather troubled by the difficulty of reconciling the ways of the first intelligence with our commonplace notions of decency. The intrigues of the father of the gods, the artifices by which he eludes the jealousy of his wife Juno, his incestuous, and, if they were not classical, we should call them filthy debaucheries, draw largely upon our faith in the beauties of these records of high Olympus; and our admiration for the poet is sadly tintured with disgust for the images in which his creative powers are developed.

Thus much of the ceremonial laws. Of the moral law, the law of God, it becomes me not to speak; its obligations are as eternal as its author; the everlasting truths of the decalogue have been incorporated more or less into every system of religion and ethics which has been enunciated during the ages interposing between us and the time when they were first promulgated on Mount Sinai.

In dismissing Moses and his times, I crave your parti-

cular attention to the manner in which the characters of priest and physician met in the same person, and as we go on we shall find that this junction of attributes continues through all the variations of time and circumstances. The terrors of the *unseen*, overawing the ignorant, placed them at the mercy of those daring minds which in every age have assumed the office of interpreters of the will of the *demon*, or the behests of the benign Deity. To deal as a mediator between the threats of the terrible avenger and the awe-stricken victim of his own bewildered imagination, to avert the consequences of the threatened storm, or to turn aside any other manifestation of approaching evil is the office of the *medicine-man* of the North American Indian and the *Obeah* doctor of the African.

Shrewd observers of nature, these wretched impostors monopolize the whole of the intelligence, such as it is, of the hordes of the human race upon whom the light of reason has never dawned, or has dawned in vain.

There is yet another aspect of the medical character, infinitely more agreeable and important, and the consideration of it will bring us to the times immediately preceding the days of the father of medicine. I do not propose to penetrate into the story of Esculapius and his divine origin, which probably, in an esoteric sense, merely meant that the Giver of all good had inspired him with a knowledge of the healing art; but (with a passing glance at Homer, the greatest poet of his own or any subsequent age), proceed to offer some general observations on the position which the study of medicine acquired under the tutorship of the philosophers.

The siege of Troy is supposed to have taken place about three hundred years before the *Iliad* was sung, and in that early time it appears that the cultivation of our art formed part of the general education of kings and warriors.

Homer introduces us to Machaon the son of Esculapius, who, when Menelaus was treacherously wounded by Paris, is called to his aid:

"When the wound appeared in sight, where struck  
The stinging arrow, from the clotted blood  
He cleansed it, and applied with skilful hand  
The healing ointments, which, in friendly guise,  
The learned Chiron to his father gave."\*

Making due allowance for the debasing fable with which every great name or talent is overlaid, it is rational to suppose that Chiron, the teacher of Esculapius, was one of those shepherd philosophers, who like their Babylonian brethren absorbed all the knowledge of the times; but Homer gives us other examples in support of this idea. Chiron was the preceptor of Achilles, and when Machaon is himself wounded, Patroclus is sent by Achilles to his assistance: on his arrival he is urged by Eurypylus, to

"Draw the deadly dart,  
With luke-warm water wash the gore away:  
With healing balm the raging smart allay,  
Such as sage Chiron, sire of pharmacy,  
Once taught Achilles, and Achilles thee."—Pope.

He also complains that

"Of two great surgeons, Podalirius stands  
This hour surrounded by the trojan bands,  
And great Machaon wounded in his tent  
Now wants the succour which so oft he lent."

Then

"Patroclus cut the forky steel away,  
And in his hand a bitter root he pressed,  
The wound he washed and styptic juice infused,  
The closing flesh that instant ceased to glow,  
The wound to torture and the blood to flow."

Machaon seems to have largely shared the goodwill of the Grecian hosts. Nestor, in his anxiety, says:—

A wise Physician skilled in wounds to heal,  
Is more than armies to the public weal.

Military leaders in our days have no such weakness as this. Studied neglect seems to them the befitting recompense of those on whom they must necessarily rely for the health and sanitary welfare of their troops.

As we are still in the age of fable, it may not be out of place to notice with what tenacity the human mind clings to those delusions which fear engenders, and weak hopes

\* Lord Derby's Translation.

sustain : with all our boasted enlightenment, the *marvellous* and the *incredible* have more worshippers than the *real* and the *true*. Let us not wonder then, that the pure *monotheism* enunciated in the Holy Scriptures had so little charm for the sensuous and imaginative Greeks. Socrates, who, by the simple force of reason and philosophy had reached the very portals of the temple in which was enshrined the idea of the unity of God, in his *last hour* "Sacrifices a cock to Esculapius." The reputed offspring of an impure deity, history is unhappily more abundant in records of human folly and superstition, than in examples of purity of thought and action—simplicity is everywhere despised—facts are distorted or made subservient to sensations, for example :—It is not enough to tell us that Chiron was skilled in physic, but to suit the depraved appetites of the vulgar he is a *centaur*, and Esculapius a *god*. It is therefore with something like relief that the name of Hippocrates comes before us for in him we have a *reality*, and in his works a remarkable record of the condition of medical science in the fifth century before Christ. He was born at Cos, a small island off the coast of Caria not in Greece proper, in the first year of the 80th Olympiad.

He was descended from Esculapius by his father's side, and from Hercules by his mother's, and was the son of Heraclides, a physician of the family of the Asclepiadæ, who furnish us with the very earliest instance of a body of philosophers devoting themselves to the healing art, for, although Pythagoras, who lived immediately before Hippocrates, and Democritus, who was his contemporary, were both learned physicians, yet whatever fame they acquired, was ascribed to their powers as mental philosophers and rhetoricians.

It has been urged by way of apology for the mystery in which the philosophers shrouded their wisdom, that "science, like modesty, should cover itself with a veil to increase the charms of the treasure it conceals," and this principle has been, throughout all ages, more generally acted upon than avowed.

The character of Hippocrates is at once a study for the physician and the moralist ; the former will appreciate the astonishing evidences which his works afford, of a deep acquaintance with the whole subject of medicine, and his admiration will be increased by the remembrance that all the principles laid down by this great and good man were the results of his *own* experience.

No treatises on disease existed anterior to his time to aid him in his investigations of the phenomena of nature, although it is true that in the Asclepion or temple of Esculapius at Cos, records were kept and votive tablets preserved commemorative of cures performed, and the remedies by which they were effected. But if the physician admires his talents, the moralist does honour to the qualities of his mind and the goodness of his heart. Benevolent and disinterested, pious towards the gods, and incorruptibly devoted to his country, he instructed his fellow-men, not by shedding manly tears over their follies, like Heraclides, nor by the coarse laughter of his friend Democritus, but by a calm and even walk of life, mitigating sorrow by his skill, and showing the form and beauty of virtue by his example.

His portrait of a worthy physician may well serve for his own likeness, and in its description we shall observe that the same exalted principles of professional ethics therein inculcated are as strictly applicable to our own times as they were to those which he himself enlightened and adorned. His words are :—"The physician who is an honour to his profession is he who has merited the public esteem by profound knowledge, long experience, consummate integrity, and irreproachable life ; who, esteeming all the wretched as equals in the eyes of the Divine Being, hastens to their assistance, speaks with mildness, listens with attention, bears with their impatience, and inspires that confidence which sometimes of itself restores life ; sensibly alive to their sufferings, carefully studies the causes and progress of the complaint ; not disconcerted by unforeseen accidents, but, in emergencies, having exhausted his own resources, holds it a duty to call in his brethren of

the healing art to assist him with their advice. Having struggled with all his strength against the malady, he is happy and modest in success, and in failure congratulates himself that he has, at least, alleviated the sufferings of his patient."

One of the great obstacles to the advancement of anatomy and physiology was the universal reverence for the dead which the Greeks and Romans shared in common with all the people of antiquity. Among the Jews, to touch a dead body exposed the offender to a penance of seven days exclusion and privation from the ordinary comforts of life, and it is almost superfluous to add, that the Egyptians made this reverence a part of their religion.

He, then, who ventured on the dissection of the human body, did so at great personal risk, and more than 600 years after the foundation of Rome no instance is known of the existence of any public professor of anatomy. About that time Archagathus, a Greek, practised surgery in Rome, and it appears that his use of the knife, and the actual cautery, was so abhorrent to the general feeling, that he was saluted with the opprobrious title of "Carnifex." Even in later days the learned Tertullian classed anatomists and butchers together in a philippic he pronounced against Herophilus, whom he charged with having tried experiments on the living body. He commences :—"Herophilus, the physician, or butcher, whichever you please, who, to become better acquainted with men, ripped them up alive," &c., &c.

Of this same Herophilus, who appears to have been a man of humour, as well as genius, there is an excellent story told, as follows :—A certain *Diodorus*, a contemporary philosopher and teacher of paradoxes, declared that there was no such thing as *motion*. "If a body *moves*," says he, "it moves into the place where it *is*, or into the place where it *is not* ; now it does not move into the place where it *is*, for what is *in* a place *remains* there, and, consequently, one cannot say that it *moves*. It also cannot move in a place where it *is not* ; and, therefore, it does not move at all." This acute gentleman having dislocated his arm, begged the services of Herophilus, who, smiling, said :—"Either the bone of your arm is moved into the place where it *was*, or into the place where it *was not* ; now it cannot move, according to your principles, either in one place or another, consequently it is not displaced at all." The poor teacher of paradoxes saw that Herophilus was laughing at him, and in an agony cried out :—"Leave, I pray you, *dialectics* and *sophisms* to me, and treat me according to the laws of medicine."

The inference that dissection was not openly allowed, will be strengthened by a short reference to the subject of the embalment of the dead—the first mentioned of this custom is found in the 50th Chapter of Genesis ; where, at the second verse, we read :—"That Joseph commanded his servants, the physicians, to embalm his father, and the physicians embalmed Israel," and at 26th verse of the same chapter it is written :—"So Joseph died, being one hundred and ten years old, and they embalmed him."

The Egyptians believed that so long as the human body could be saved from putrefaction or decay, the soul of that body continued in existence ; and from this feeling arose the custom of embalming, so common in remote ages. The embalmer was, in a certain sense, a *sacred* functionary ; nevertheless, it was the fashion to make a show of resistance, when he began his operation, in order to mark the innate horror of any, however necessary, profanation of the dead body. Herodotus relates that in Egypt the mummy embalmers made the incision in the side of the corpse with a sharp, æthiopic stone. Of these stones two varieties have been found in the tombs in Egypt, both of chipped flint, and very neatly made. One kind is like a very small cleaver ; the other has more of the character of a lancet. The account given by Diodorus Siculus of the resistance offered to the embalmer is, as follows :—"And first, the body being laid on the ground, he who is called the scribe marks on its left side how far the incision is to be made ; then the so-called slitter (*parachistes*) having an æthiopic stone, and cutting the flesh as far as the law allows, instantly runs off,

the bystanders pursuing him, and pelting him with stones, cursing him, and, as it were, turning the horror of the deed upon him, for he who hurts a citizen is held worthy of abhorrence.\* Immediately after death the corpse was put into the hands of the enbalmer, who, in the presence of the friends of the deceased, made an incision into the left side, as above described, through which he extracted all the intestines, leaving the heart and kidneys; the intestines were then washed in palm wine, and a solution of astringent gums. The brain was removed through the nostrils by means of a hooked instrument, contrived for the purpose, and the cavity filled with aromatic oils. The body was now anointed with spice-oils and balsamic gums (frankincense being prohibited), and allowed to remain for thirty days, after which it was immersed in a solution of nitre for from forty to seventy days (the latter being the extreme limit allowed); it was then enveloped in aromatised cere-cloths, and all being ready, consigned to the coffin, on which were painted emblems indicative of the condition of the deceased.

### THE INFLUENCE OF THE DISCHARGES AND NERVOUS SHOCK ON THE COLLAPSE OF CHOLERA.†

By JOHN COCKLE, M.D.

PHYSICIAN TO THE ROYAL FREE HOSPITAL.

(Continued from page 183.)

Dr. LENEY, a physician practising in Bray, has, within the last week or two, recorded cases of what he terms "Contagious *Hæmorrhœa Serosa*," a disease it appears, differing from epidemic cholera; here, the discharges were immense, cessation of the pulse, and other phenomena of collapse rapidly occurring.

An escape of the constituents of the blood so sudden, rapid, and excessive, seems almost incredible until we reflect upon the vast extent of the surfaces engaged, the capacity of the tubing to receive and, for a time, the almost boundless sources of supply. Secretion it is not, but one almost incessant current from myriads of minute converging streams knowing no let or hindrance save that afforded by the frail barrier of the limitary membrane of the tract.

Researches, comparatively recent, have thrown some light upon the physical phenomena of currents traversing membranes, and the means to moderate or, even to reverse, their action.

Dr. Alderson, in a recent lecture on cholera, has ably applied the experiments of *Matteucci* and *Bacchati* respecting the process of exosmosis, to the escape of fluids in cholera. There can be no doubt that his explanation greatly aids us in understanding the physical phenomena of the current, but it fails (as I suppose he would concede,) when applied to the higher causation of the malady; it does not reach those vital changes which precede and determine the rush of fluid to the membranous walls of the stomach and bowels.

Not to break the filiation of the argument as regards these simple, though profuse evacuations, we have to consider them in their immediate connection with cholera—as the destructive and not eliminative elements of the disease. If we bear in mind the fluids lost by the premonitory diarrhœa, and the amount of serous vomiting and purging coinciding with and following the developed disease, such a dissipation of the fluids seems alone sufficient to produce the extremest degree of collapse independently, even of the primary nervous shock to be referred to subsequently. I reproduce the testimony of Schütz of Berlin who has had immense experience in cholera. He states,

I have known patients brought into the hospital with but moderate vomiting and purging and no unusual depression of temperature or of pulse; before my very eyes, these patients suddenly passed enormous serous discharges from the stomach and bowels, and *pari passu*, sunk into the most perfect algidæ stage. This is no unusual result, cholera literature abounds with such. I do not see how such losses can be regarded otherwise than destructive, totally disproportioned to any critical requirements, and, determining all the symptoms it is our object to prevent.

So far for the outward indications of discharge. Let us now trace it in its hidden form. This stage of the pathology of cholera is of the highest importance to investigate, since it is alleged that cholera can prove fatal, by sudden collapse from the influence of the poison on the blood, without the customary drain. The power of cholera, suddenly to kill, I can neither affirm nor deny, but, I may say that such a mode of death is not seen in this country. That an intense influence of the agent when it has begun its action in the gastro intestinal tract may quickly, indeed, simultaneously, paralyse the heart, intestines, and, arrest nutrition, is certain, though never, I believe, without internal transudation. The fact, however, of comparatively sudden death has been so confidently stated, that we cannot evade such fact, neither ought we to attempt it. Mr. Jameson, in his graphic account of an outbreak of cholera in the camp of the Marquis of Hastings and, subsequently, during a march, speaks of hundreds rapidly falling, dying or dead. We must, however, liken this to the general description of a battle; striking incidents, only, are narrated, while minuter detail is left to later despatches. But, with regard to this very class of cases, the experienced Indian pathologists are scantiest in their *post-mortem* results. In any disease, with a well known pathology, we may, occasionally, find exceptions in some particulars, which would not vitiate the general result; but when such exceptions are selected to form the basis of a theory, it clearly behoves us to challenge and to scrutinize them most exhaustively. I must, therefore, endeavour to supply the *post-mortem* deficiency alluded to, from the experience of investigators nearer home. Cruveilhier, whose reputation as a morbid anatomist needs no eulogy of mine, made between two and three hundred examinations of cholera patients, and thus expresses himself with reference to cases unattended by much outward discharge. "It was particularly in individuals who had only passed a few choleraic discharges that this enormous quantity of fluid was discovered in the stomach and bowels after death;" again, "some patients did not pass during life, one single alvine evacuation, but, notwithstanding, their intestines were found after death, filled with the peculiar fluid." Those most accurate pathologists, *Reinhardt* and *Leubuscher*, state "In general, death occurred after the period of the very frequent and excessive discharges; there were exceptions, however, for many patients died before the rice-water secretion contained in the bowels could be evacuated." Scot, also, declares "that the stomach and bowels have, sometimes, been found after death, filled with fluid, though no vomiting and purging had been observed." To finish with one more very recent statement; Dr. Leney, whose observations have been before referred to, in drawing a contrast between "*Hæmorrhœa Serosa*" and epidemic cholera states, in reference to the late epidemic of the latter in Ireland, that those cases in which the secretions were retained, no evacuations taking place from the stomach and bowels, proved the most suddenly fatal, and, on *post-mortem* examination, both stomach and bowels were found distended with sero-albuminous fluid, almost to bursting. Numerous other confirmations might be cited to show that, while some patients die from shock and profuse external discharges, others, die from shock and from the same discharge though, during life, it is concealed from view, and not from any poison uneliminated from the blood. We must not, therefore, when a patient is brought into hospital, cold and pulseless, yet with but little drain, infer they die from poison in the blood; their history generally shows profuse antecedent discharges, and the abdomen is still dull to percussion and

\* Taken from E. B. Tyler—"Early History of Mankind," p. 217.

† Read before the Medical Society of London, Feb. 11, 1867.

resistant on palpation; neither must we forget that with the squalid and ill fed poor, though no real disease exist, their power of vital resistance is at times so low that discharges, comparatively small, may cause a fatal collapse. That recovery can take place under drain, is certain, but not as it appears to me, from any further elimination of poison from the blood. The excretion of fluid, is, I am quite sure, sometimes the result of returning power of the canal, and also, an evidence of the return of general reaction.

From the consideration of this amount of serous fluid either ejected from or retained within the gastro-intestinal canal, we naturally turn to the condition of the blood from which the abstraction has been so suddenly and directly made. How greatly changed it is both in its vital and physico-chemical endowments, all admit, however opposite the theory that each may hold. We may even proceed a step further and affirm such changes to be sequential, at least, that none, appreciable to sense, attend the onset of the disease. *Majendie*, than whom none could have had a larger experience in cholera, inasmuch as he attended between five and six hundred cases, states "I have seen on numerous occasions, in England, bleedings before the algide stage, at two or three hours interval; it was not possible to detect any difference between the blood drawn and that of a non-choleraic subject. \* \* \* It is worthy of remark that the blood is not changed at the onset of the disease, but gradually, as it progresses, hence I infer that the alteration is the consequence and not the cause of the disease. Permit me further to quote the testimony of two very competent Indian observers. *Scot* writes "It is established by the replies to this letter, as well as by an immense mass of concurrent evidence, that the blood is of an unnaturally dark colour and thick consistence. These appearances are very uniformly expressed by the terms dark, black, tarry, in regard to colour; and by thick, soapy, syrupy, semi-coagulated in respect to its consistence. The change in the condition of the blood is, likewise, fully proved to be in the ratio of the duration of the disease; the blood at the commencement seeming to be quite natural, and, more or less rapidly assuming a morbid state as the disease advances." *Searle* also, states "It is established by undoubted evidence, that the blood is of an unnaturally dark colour and thick consistence; these changes in the condition of the blood are, likewise, fully proved to be in the ratio with the duration of the disease."

The examination of the residual blood shows, that, in all epidemics, the total amount is diminished. In some cases, doubtless conditioned on the extent and continuance of the drain, the quantity remaining is so small, that scarcely a pint can be collected free. This amount of varying consistence, is massed in the heart, lungs, pulmonary arteries and veins. The systemic arteries are generally empty, and the large organs more or less anæmic. From the admitted density of the residual blood, and from the special losses it has sustained, we can easily conceive many of the physical characters accorded to it. But, with regard to the changed colour of the blood? not a relative darkness from simple aggregation, but one absolute, and all important. Let us not forget that the black colour did not exist at first; whatever its cause, it is the consequence of the progress of the disease. It cannot always be the result of obstructed passage through the lungs, since, during the early part of the cyanotic stage, the left ventricle contracts, and arterial pulses are still, though feebly, to be felt. They do not beat on air, and we can have no better proof they circulate black blood, than the fact well and repeatedly ascertained that, if an artery is opened during life or rather before its immediate close, the blood exhibits the same well-marked black colour. With a view to the possible solution of this problem, we must enquire afresh into the effect of the sudden and excessive abstraction of the plasma as specially affecting the blood disks. When a given quantity of the plasma has left the main vessels, and all available sources are cut off for remanufacture, the disks are said by *Schmidt*—one of the very highest authorities on the subject—to permit

exosmosis of their proper nutritive elements into the main current. They yield in part their globulin and hæmatin—elements as important in the life-history of these microcosms, as they themselves are in that of the macrocosm of the body. So that we have injured disks, and white corpuscles retained in a fluid, which has been robbed of its water and salts, partly spoiled as to its fibrine and albumen, and altered, as to its consistence. It is precisely at this juncture, as I believe, that change of colour commences which explains, in part, the subsequent phenomena. If the nutrition of these minute, though important organisms is dependent upon a standard composition of the blood plasma, and, if this fluid is modified as supposed, is it surprising that the disks, after the loss of their own internal pabulum, should participate in the disorder and become, at least temporarily paralyzed as it were, and unfitted for the object of their ceaseless journeyings—outward bound with oxygen for distant capillaries, and homeward laden with carbonic acid which they should discharge into the air cells. That they are, now, inadequate to the final end of their normal freightage is probable, since they pass the lungs unpurified and onwards to the left heart, systemic vessels and coronary arteries, in which last, they powerfully concur, in combination with nervous shock to bring the circulation, gradually to a stand still. By nervous shock is implied, not alone the primary depressing influence of the poison, but also, the exhaustion induced by vomiting, purging, and cramps.

There is nothing speculative in the above statement, for *Rayer* has conclusively shown that no chemical change occurs during either inspiration or expiration as the algide stage progresses; hence, the warm breath of health is replaced by one of unnatural coldness.

With regard to respiration generally, the respiratory centre is but slightly modified, the mechanical part of the process is essentially perfect, though, often, accidentally impaired by the severe cramps of the abdominal, thoracic, and diaphragmatic muscles. In a published memoir, I have stated as the result of my observations, that embarrassed breathing is not of constant occurrence in cholera. So essential is it to have a clear understanding on this cardinal point that I shall quote fuller evidence in support of my assertion. "Respiration is often nearly natural when the pulse is gone."—*Mackintosh*. "In the algide stage the respiration is sometimes natural so far as regards the number of respirations and the extent of the movement."—*Majendie*. "In the algide stage, the respiration is sometimes natural, at others, quickened or slackened."—*Cruveilhier*. "Respiration is not usually interrupted in the early stage unless by spasm."—*Scot*. "It has been shown that cholera asphyxia affords a remarkable illustration of the fact that respiration may continue free after the circulation, to all appearance, has ceased."—*Bell*. "Respiration is not, usually, interrupted in the early stage of cholera. In many cases terminating in death, respiration has gone on in its mechanical part with little or no interruption except, that it has become slower and slower. . . . In natives, respiration is, generally, pretty free until the very last."—*Searle*. "In many cases the respiration was quite calm till death."—*Reinhardt* and *Leubusher*. "I have known the respiration to be quite easy, and noted it as such, while the cramps, coldness, small, rapid arterial pulse and inelastic skin indicated the advance of collapse."—*Horace Jeaffreson*.

It appears, then, that in a very large proportion of cases, no true lung dyspnoea—no marked "besoin de respirer" necessarily exists although in some cases, it has, doubtless, been observed.

The testimony afforded is that of the very best observers, —and the results of pure clinical study.

Every theory of cholera must, in common with the other established data, submit to be tested by such evidence, and, if it will not stand such test—will not square with all the pathological facts of the disease, it fails in the required comprehensiveness.

During the cyanotic and glacial stages we may infer then, that some amount of black blood circulates for a time,

as in cases of congenital cyanosis, but why, in cholera, the brain, the only support left of the great tripod of life, should preserve almost to the last its higher functions intact, is a problem which neither the time nor my ability would permit me, properly to discuss.

That the condition of the blood is such as has been described is rendered more than probable from the effects so instantaneously following saline injections into the veins. Shortly after the fluid has entered the vessels, the colour improves, the temperature rises, the pulse returns, and the tissues again fill out, showing that hæmaturia is restored. When the injected fluid transudes, the collapse stage again returns, to be again removed by fresh supply, so that, *cæteris paribus*, this alternation might be almost indefinitely prolonged. In some well nigh hopeless cases, as in the recent remarkable one recorded by *Lorain*, one injection of 400 grammes of water at 40° Centigrade, saved the patient's life. Such results would seem to show that the condition of the blood does not so much depend upon any active general poisoning as upon such an abstraction of the nutritive material from the globules and plasma as temporarily arrests the physico-chemical conditions under which they normally act.

Algid fever, of all other affections, best illustrates the second influence contended for,—*shock*, or whatever neurotic change is comprised under it.

This remarkable affection, one of the forms of that portean malady, "*Pernicious Ague*," has been so thoroughly investigated by *Maillot* that we may confidently trust to his description.

The phenomena of alidity appear, not as a termination of the ordinary cold stage, but often, amid the best marked reaction. Suddenly, the pulse becomes quick and weak, falters, then ceases altogether; now,—but always subsequent to the arrest of circulation, the temperature, though unfelt by the patient, rapidly falls to a glacial point, and the surface assumes the cyanotic hue; respiration continues free; the cerebral functions are intact to the last. Some instantaneous change has unmistakably occurred in the nervous centres, no other view could account for such phenomena. Life is at once in the balance, and should serous vomiting and purging supervene, is almost certainly lost.

Here, the analogy between the two affections appears most striking and strongly points to the neurotic character of both. *Pernicious ague* might explain the death from coma said to occur in cholera, coma being one of the most common terminations of the former disease; it might further aid our explanation of those cases characterized by such rapid failure of the circulation and the temperature as are described in cholera: in both, the blood is black and stringy; in both, the heart is robbed of its contractile power.

Cholera, by universal consent, has been regarded as a mysterious disease. It doubtless is so. Yet more, perhaps, in the sense of the riddle of its proximate causation than in that of the fulness of its pathology. It is not like a violent shock fatally depressing the circulation through the nervous system; here, there may be no loss. It is not like a simple, though dangerous hæmorrhage, since here, although the vessels pour out their contents yet, should the circulation rally, there still is left some pure blood, a contractile heart, and magazines operative for repair and immediate fluid supply to the vessels. It is not, altogether, like *pernicious ague*, for here, paroxysmal recurrence of algid phenomena is the law. Cholera is, so to speak, the sum of these influences combined. It is the result of some special agent profoundly modifying the function of the extensive gastro-intestinal tract—rapidly radiating back a paralyzing influence on the great nervous ganglia connected with the spino-sympathetic centres, and suddenly abstracting from the circulation, under such depression, a large amount of blood constituents without any capital left wherefrom to write off the loss. The vital powers thus taken, as it were, by surprise, too frequently yield before they can, in any way recover.

Cholera, seems, then, in its very essence a disorder of

function and, moreover, one of special functions. Upon reviewing the phenomena of animal and organic life, we found in the former, the intellect intact, volition to some extent, still active, and the muscles obedient to its mandates; the mechanical play of respiration unless from spasm, unimpaired. Look to the spino-organic system and all the disturbance that we find, seems centered here, so that if it were not so old-fashioned, one would still maintain this system to be the great centre of *functional*, I do not say *organic* change, for that would bring back the old objection that no such changes are patent to our coarser or even aided vision. But, if cholera be a functional perversion, what changes could we expect to find?

Numerous theories have been since advanced, many of interest enough to arouse attention; none of weight enough to enforce belief. The old view, then, associated with the names of *Loder* and *Delpech* may relift its head, though robed in modern garb—in a functional and not organic aspect—as a secondary, and not a primary causation.

To ascend to this causation, two conditions must be satisfied; adequate knowledge of the laws which govern the acting agent, and a more precise acquaintance with the functions of those portions of the nervous structures upon which such agent does directly or, indirectly act. The latter knowledge may, probably, be a future conquest of Experimental Physiology. We want *Claude Bernard* to do for the abdominal, that which he has done for the cervical portion of the sympathetic. But, if we could admit *paralysis*, equivalent to *section*, we might even carry the light of his researches here, and find a given sameness in result, decided augment of temperature of the internal parts of the abdomen and, an undue supply of blood to the capillaries of the gastro-intestinal tract.

I have thus adopted what appeared to me the easiest method of accomplishing my task. If the nature of the disease is sought for in its fully developed, complex state, all past experience shows that it eludes our grasp. But, if the method is reversed, and we estimate aright the simpler elements—what part the discharges play, and what the nervous influence, the difficulty of the enquiry may be thereby, somewhat lessened.

In conclusion let me observe that this paper is to be regarded simply as suggestive. The time, seemingly, has not yet come to justify any dogmatic assertions. We must still pass the old question on. We require, it is superfluous to say, a constant faithfulness in our record of individual cases—a pure record unvarnished by any theory; but what I think a still more urgent need is, of a good clinical and pathological history of the various epidemics, showing to what extent, in each, the disease may have departed at times, from its ordinary type; and tracing, if possible, the conditions under which such variations have occurred. This is the only way to reconcile differences which, unquestionably occur, and to explain contradictions which are awkward and illustrations of the common fallacy of drawing general pathological conclusions from the *data* of a particular epidemic.

I have endeavoured, to the best of my ability, with one exception, to keep as evenly in the track of fair argument and established fact as the subject would permit. To ascertain to what extent you can approve the argument and accept the facts, is the object of the paper you have been good enough to listen to.

## REMARKS

ON

### AFRICAN, WEST INDIAN, AND OTHER FEVERS AND DISEASES.

By ALEXANDER LANE, M.D., Surgeon Royal Navy.

(Continued from page 186.)

This disease called "fever" is subdivided into "stages," according either to its duration or peculiar appearance; all those symptoms will depend in each case upon some peculiar idiosyncrasy or habit of body, and then there will be some apparent difference, though none in reality. A man

in perfect health will say, quite unexpectedly, "I don't feel at all well; I feel sick; I'll go and lie down." Shortly after he feels cold, and the rigors commence, more or less violent, according to the virulence of the poison; bed-clothes are heaped upon him to procure warmth, but of no avail; he shivers and shakes until the paroxysm is over, and then what is called reaction takes place; then will be quick pulse, hot skin, headache, &c. These symptoms, then, are called "fever;" this is the beginning, and it depends upon the locality, what name it gets; as in the tropics it would be called "yellow fever," and in a more temperate clime, simple, continued, or active inflammatory fever; but it does not get the name of typhus, or putrid, until it gets more advanced and symptoms denoting putrescency set in. The virulence of the poison has not been checked; it continues to exert its fatal influence upon the system, and thus gradually proceeds from bad to worse, until it has arrived at what is called its last stage, when death, in all probability, finishes the scene.

But, supposing that, by some chance—as the specific is yet unknown—that medicines have been given which have neutralized the poison, then the result is evident; the symptoms gradually secede, convalescence follows, and, of course, there are no such things as stages. I believe it to be a fact that, in all "fever," the cause is totally ignored, and the physician contends solely with the symptoms, which he designates a disease. But, if the poison is too powerful, the result may easily be anticipated. I am well aware that one person will recover from, whilst another will succumb under, the same mode of treatment; and that the same will take place under different modes of treatment from either, such depending upon the action of the medicine on the system in each case; but I would feel rather disposed to attribute the recovery in such cases more to the strength of the constitution or mildness of the poison than the virtues of the medicines, unless, indeed, some of them might have acted specifically; besides, many cases are set down as fever which are only "febrile," arising from some local irritating action. These cannot come under the designation of the disease called "fever," produced by a specific poison, and are all, generally speaking, removed by simple means.

When fever makes its appearance, it does not follow, as a matter of course, that all will be attacked; some will escape though in the midst of it, and why? I think the reason is very obvious. There are some who, from some peculiar idiosyncrasy of constitution, are not susceptible of the influence of the poison, and therefore escape its fatal consequences. It has been said that a person acclimatized is not susceptible, either in the tropics or elsewhere; but this is a great mistake. Certainly, they are less liable. A great deal depends upon the manner of living, and the care taken. An old resident will seldom commit heavy debauches, so as to render his constitution in any degree susceptible, knowing full well the result, and should he do so the chances would be fearfully against his imprudence, the vigour of the once strong constitution having been seriously undermined by the great relaxation produced by one long continuous heat, for a lengthened period.

An epidemic does not sweep off the entire population, those who are unsusceptible of the "mal aria" will escape though they are walking in its very midst and breathing its noxious virulence. I once saw at Sierra Leone, the inhabitants of one side of a street attacked with this malady, whilst those of the opposite side escaped, and though there had been communication, no evil consequences followed. This was attributed by some to a row of trees in front of the houses, which they said arrested its progress. People are astonished when an epidemic appears amongst them, and perhaps, they soon find out that a similar disease has appeared in another locality; then they endeavour to trace its origin to that locality; and should they succeed in establishing something, however remote or ridiculous, they will greedily seize upon it, as if it were impossible for it to have appeared there without some kind of transmission, forgetting that a similar cause may have existed at both places at the same period.

Let the thermometer stand at, from about 75° upwards, for six or eight months steadily in England, and you will have just as fatal a disease in all parts of it as ever ravaged Africa or the West Indies, we only want the heat—there is material sufficient.

The cattle plague was said—I believe some have positively affirmed it without positive proof—to have been brought over from the Continent, by cattle; and a commission was sent over to enquire into its character and origin, and what did it find? nothing; what did it discover? nothing; but, that there was the disease, and since then it has appeared in different parts of England and elsewhere, where no communication had been. The commission made an elaborate report, as in duty bound, and set the disease down as highly contagious, leaving its cause or origin in total darkness—though that must evidently have been atmospherical poison, a cause which may exist anywhere, when the means for its production are to be found.

If the remote cause of disease does not exist in the production of some peculiar poison from the earth, where does it exist? can it be in the food or drink? I think not. The poison of one disease is quite different from that of another, and yet all, in my opinion, are the produce of the earth, disseminated through the atmosphere, absorbed through the lungs, thrown into the circulation, and each appears in its own proper guise and form. There is no disease in which the blood is not poisoned to a certain extent, because the same disease will appear more or less violent, according to the extent and virulence of the poison and the susceptibility of the constitution. Look at cholera, which is produced by a most virulent poison, and for which no antidote has as yet been found; therefore we are left to fight against the terrible symptoms it produces in the best manner we can. I wonder the Government has not sent a commission into the East to look after its cause, origin, &c.; yet it has proved itself in many cases perfectly sporadic, and has appeared in places, times, and seasons when not expected. The measles or small-pox suddenly appear amongst us. Where do they come from? I knew an old lady, aged 80, die from the former, and she was the only one in that district who had them, nor were they communicated to old or young.

If the poison is in the blood, which I believe it to be, how can symptoms communicate the disease? In close and crowded, badly ventilated rooms, where there is want of cleanliness, pure air and attention, and no change of bed-linen, something very disagreeable will no doubt annoy the olfactory, but will the absorption of this produce disease? I am not prepared to say that it will not produce a similar disease, but much less violent in character—and, as I believe, without the rigors—in those who are susceptible than when produced by the original virus; and yet I would rather attribute it to the original cause, because we have no positive proof.

Where we find a disease yield to one or two medicines we may safely say that one or both are specifics against the peculiar producing poison. Where there is disease, as I said before, there is impurity of blood; therefore, the sooner we alter its condition the better, and the sooner will the affection disappear. If we cannot do this, it must linger on. Give what medicines you will, you look forward to their being absorbed and thrown into the circulation, for the purpose of acting upon some particular organ, or part, or perhaps the whole system; therefore, it is evident that if you do not wish to alter the circulating medium, you wish to put into it that state which will, or ought, to affect particular organs or localities. When you inoculate for the small-pox, do you not poison the blood? Therefore, is not the blood poisoned in all irruptive diseases? I think so. Therefore we require an antidote to the poison; if we do not possess this, is it not self-evident that treating the symptoms is all speculation? That the virus is in the blood is an undeniable fact. The patient recovers only when the strength of the virus is worn out by some peculiar tenacity of constitution, or perhaps the unconscious exhibition of an antidote, unexpected recoveries have taken

place, and to either of those I would attribute them. I never could see the propriety of slaughtering healthy cattle. When cholera makes its appearance in the village of a despotic sovereign, he might with as much propriety slay all its healthy inhabitants to prevent its being communicated to other parts of his empire. There can be no doubt about precautionary means, but I think we have had proof sufficient that all our remedial measures will not prevent the appearance of disease, nor will it appear in a place where there are not the means of its production.

When the symptoms are very violent, with a high thermometer, the finer tissues are in danger from inflammation from the continued and excessive injections of arterial blood, you must therefore, reduce arterial action. Bleeding will do this, and at the same time remove a portion of the poison, but it will not cure, there is poison behind. The inflammation produced is of a peculiar and specific character. Croton-oil will also have a desirable effect if given in sufficient quantity, so as to procure several free evacuations in the course of an hour or less; some think this too drastic a purgative, but I have not found it to be so. When applied freely to the tongue, or dropped upon sugar and swallowed, it acts as a poison, and its effects are sudden. Its passage, like other purgatives through the entire tube, is not required; hence there is less irritation, and the exhaustion which follows its operation is not like that which follows purely drastic purgatives. The symptoms are all much lessened in violence, the secretions are all brought into activity, and the system is rendered ready for the absorption of active medicines, such as mercury. The medicine which I found to be so serviceable was the pure nitrate of potash, in large doses, so as to saturate the system with it. It is a powerful antiseptic or anti-putrescent, and, as such, is an antidote to the poison; but as it was apt to induce gastric irritability, I tried another medicine which prevented this, whilst it added to its influence. With regard to counter-irritation—such as blisters for abdominal pain—I found that they did not produce the same effect as when that was idiopathic, not depending upon the poison which was circulating through its vessels. The pain of the application being deceptive has often misled the practitioner, as it in nowise lessened the internal action.

The trouble and expense taken with the idea of preventing the introduction of disease are most decidedly all praiseworthy, yet they do not and cannot prevent it, as we have had such sufficient proofs; and yet we allow a disease which is far more fatal, and, for aught we know, just as contagious, to stalk through the length and breadth of the land without let or hindrance—I refer to consumption. How do we know that it is not a contagious disease? Why not as contagious as the others? Is it because there is no heat of skin or violent headache? It carries off its thousands and tens of thousands in the most insidious manner, and yet there is not one word about its being contagious. Why may not the exhalations from one lung be absorbed by another? I see nothing to prevent it, yet all are silent upon the subject.

There is not a single symptom, however minutely described by authors and others, there is not the finest portion of disorganized matter, that is not produced by poison in the blood—call it impurity if you like, or anything else, there is something in it which should not be. Where the blood is pure there is no disease. I speak generally, and do not refer to sudden local affections, and whatever medicine or medicines will purify it, or remove that which is foreign to it, should, I think, be considered in the light of an antidote or antidotes, either in the constitution generally or in the particular local action.

When anything, no matter how trivial, puerile, or absurd, has obtained for itself a sort of ascendancy, name, or fame, real or imaginary, and it has obtained the sanction of time, it is a most difficult thing to disabuse the mind of the supposed fact; for the fact may be that it has never been disputed, that no one has ever doubted; that it was not a fact; hence when it is sought to be proved that this fact is in reality not only a supposition, but a non-entity,

few will be disposed to acknowledge that they have been living for so long a period in ignorance. How difficult it is to remove from the minds of millions, illusions of the most formidable character, established in the darker ages, both from ignorance and superstition; indeed the former is the progenitor of the latter, and how fondly they dwell upon such false idealities. Talent, education, and false pride are loth to give them up, even when positive facts are adduced to prove their incongruity, yet, some time or other, they must yield to the rise and progress of science and art.

Having thus, in some degree cleared the way, and endeavoured in a few words to explain that there are such things as misnomers, names given to that which does not exist, it is but right that those who are capable of judging upon such matters, and who can fully appreciate the beauty of consistent parts should judge for themselves. I do not see why this disease should be called "fever," except so far as heat of skin is concerned, and then it is only a febrile symptom; and as this symptom is not more prominent than any of the others, I cannot see why it should get the preference. Heat of skin seldom exists without some other local or constitutional disturbance, and, however delicate that is, there is always some arterial derangement. Where there is no violent reaction, or reaction more than ordinary, the exciting cause is proportionably mild, and where there are no rigors, where the symptoms are induced by some local excitement, they are generally removed by mild means, not requiring any active specific treatment. What produces rigors? they must have some cause, then what is it? When no positive cause can be assigned, must we not refer it to something atmospherical. A poison hostile to the system, absorbed through the lungs and thrown into the circulation produces the first shock; the symptoms which follow are merely the result, the system endeavouring to rid itself of this poison, whatever it may be—then how can a symptom be a disease?

## Lectures.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE GULSTONIAN LECTURES.

By Dr. REGINALD SOUTHEY.

ABSTRACT OF LECTURE I.

DELIVERED FEB. 27, 1867.

THE NATURE AND AFFINITIES OF TUBERCLE.

THE term tubercle has been vaguely applied to any little adventitious lump by ancient authors. Within the last two hundred years this name has been specially bestowed upon two kinds of substance found in the body, the one of cheesy or cretaceous consistence, the other pearly, grey, coloured, and transparent.

Carswell was the first to see that neither colour nor form were attributes that could be relied upon in distinguishing tubercle from other things.

Rokitansky ascribed those forms to tubercle, and considered that all were varieties of one common basic orastina, itself a qualitative anomaly of the fibrine of the blood. He concluded that the organisation subsequently attained by action of these forms must have been an after-process impressed upon the original structureless exudation.

A development by *cytogenesis* of cells and nuclei, he classified the three forms together under one common appellation, because he believed them to be manifestations of an identical blood dyscrasia expressed in different degrees.

Lebert reckoned the one feature in common to the three forms of tubercle to be a peculiar corpuscle or cell—a cell, however, to which no real specific value can attach, since it is noway distinguishable from an ordinary compound granular cell.

Virchow defined tubercle to be a new growth, organized

from the first moment that it is capable of separate identification, and classed it among that group of tumours which are constructed upon the pattern of lymph glands, and which stand most closely in relation with connective tissue formations. He attributed two forms to tubercle, "a fibrous" and a "cellular," the one being nearly a modification of the other, and thus modified only by masses of the external conditions of its growth.

Tubercle forms a simple or conglomerate tumour, and possesses all these elements—cells, nuclei, and fine granules that are normal constituents of lymph glands, only grouped after an abnormal manner, and presenting themselves in parts which ought, properly, to furnish no structure of their kind. It has a build of its own, but the form ultimately attained by the tuberculous mass is vouchsafed by the external conditions of its growth. In the parenchyma of solid organs, its final shape is round, or roundish; upon free surfaces it is more or less flattened.

The cellular composition of tubercle is its idiosyncrasy, when it can pursue its own peculiar course unembarrassed by complications. Its specific cell, specific only in that it forms the principal element of its period of highest aim, is a real cell, not a nucleus, nor a solid body, colourless, transparent, and having one or more small shining nuclei in its interior. The cell on which Ghiji and Lebert laid so much stress is a much later element, significant of the stage of retrogressive metamorphosis. The true tubercle cell of Wedl proceeds, by endogenous development, out of connective tissue cells or some embryonal modification of these.

The single tuberculum can then be seen, under the microscope, to be composed of three layers or rings; an outer of connective tissue fibrillations; a middle of perfect cells, packed close together, and passing by gradual transition into what cannot be distinguished from fine nuclei; and these nuclei again dwindling down into amorphous central granules.

The elements of tubercle are pre-eminently short-lived and degenerate, through a retrogressive fat metamorphosis, which is conducted under peculiar conditions of deficiency in moisture, such as serve to affix a special stamp upon the subsequent proceedings.

The simplest issue of the most uncomplicated form of tubercle is a species of dry crumble from within outwards. The denser, tougher, and more fibrous the structure is in which tubercle is developed, the more slowly retrograde changes are brought about in it; whereas, the softer and moister the matrix tissue of the growth, the more rapidly this breaks down and shells out.

When the external conditions are neither especially moist nor dry, the transition of tubercle is favoured towards a cheesy mass in which state it obtains its longest period of persistence.

Finally, grey and yellow tubercle differ from each other only in the amount of accidental interposed fat elements that they respectively contain. The more yellow being, as might be supposed, that which is most rich in fat. The grey granular tubercle softens at a peak point, the miliary nodule seated in the parenchyma of a solid organ softens at its centre, and peripheral softening affects the conglomerate form only, when the change ensues not spontaneously from any inherent proclivity of the mass, but is induced by external influences, such as inflammation or excess of moisture in the surrounding parts.

The lecturer then entered upon the progress and metamorphosis of the tubercle growth in particular tissues, specifying the changes that it underwent when exposed to peculiar external influences, illustrating the several points from the development of tubercle upon mucous membranes, in bone, in nerve substance, and in the kidney; he considered that it would be profitless to discuss how minutely the views which had formerly been entertained upon the origin of tubercle, first, because any caseous mass was thus reckoned by older writers, and secondly, because the opinions as to its nature have been too exclusively derived from its pusora in pulmonary tissue when it is always difficult of recognition, and most speedily deviates from its external state.

## CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REMARKS ON CHLOROSIS AND HÆMORRHAGE.

(Continued from page 189.)

OCCASIONALLY I have observed chlorosis to have arisen, as it were, spontaneously, and without the intervention of any one of the usually assigned causes; and that too within a very short period of time. I have noted cases in which the transition from a state of apparent health to that of fully formed chlorosis, has not occupied more than a week or ten days. Such a disease, thus rapidly established, and without any palpable cause, strikes one as a very singular phenomenon.

Equally remarkable is the slow and gradual development of the disease in young persons not exposed to any influence whatever, to which the disturbance of the health could be referred. When a cause has been in operation, which we can seize upon to account for the altered aspect and condition of the patient, our wonder is less excited; but when, on the minutest scrutiny, we are unable to discover any cause capable of giving rise to the disease, we are naturally led to inquire, how can this be? I have seen the disease to arise in young persons placed in circumstances the most favourable and conducive to health; and have been unable, after the most careful investigation, to discover any cause, either in the habits of life, or the affections of the mind, sufficient to account for the great change which had been wrought, the remarkable depression of the vital energies, and the totally altered colour and complexion. Can we throw any light upon a subject involved in so much obscurity? The result of many observations which I have made is, that the source of the morbid action is struma. The imperfection of organization, hereditary or acquired, usually termed struma, is the source of many constitutional as well as local evils. Amongst the former is chlorosis.

Of those affected with this disease, a very large proportion is strumous. In no instance have I met with a case of spontaneous chlorosis, except in a member of a family, upon each of whom the characteristics of the strumous diathesis have been unequivocally impressed. Though this does not explain all, it gives, at least, a clue to the interpretation. We shall, however, postpone any further remarks on this part of the subject, as they come more properly under the consideration of the signs and evidences of the strumous diathesis.

We cannot dismiss the subject under consideration without making some allusion to what may be termed the essential treatment, without instituting the important inquiry,—do the resources of art furnish us with any substance, mineral or vegetable, capable of restoring to the blood its normal density, and its due proportion of red corpuscles? The answer to this question points at once to a mineral, the efficacy of which is as remarkable as that of any other medicine in the whole catalogue of remedies; neither do bark, nor mercury, nor wine, nor bleeding, nor opium, nor antimony, even when most judiciously administered, exhibit effects more manifestly therapeutic than iron does in this disease; nor does iron bring more of wealth to the inhabitants of the country from the bowels of whose earth this valuable ore is dug up, than it does of richness to the blood of the chlorotic patient. It is remarkable, too, how universally diffused are chalybeate springs, as if it were the design of Nature that iron in abundance should

be mingled with the blood, and that it should be incorporated largely with vegetable matter. Whether the preparations of iron produce their effects directly by augmenting the proportion of red corpuscles in the blood, or indirectly by invigorating and improving the digestive function, still there is no medicine the curative properties of which are more fully established. The probability is, that it acts usefully in both ways. Iron, then, judiciously administered, is a most valuable and important therapeutic agent. Nor is its salutary action restricted to chlorosis; there are many other pathological conditions of the animal economy over which it possesses the same power in improving the blood, and thus restoring tone to the nerves and vigour to the muscles. Often in chlorotic patients have I watched the change wrought in the system from day to day under the vivifying influence of this remedy, and most striking, and sometimes rapid, have been its health-restoring effects. Were all cases of chlorosis simple and unmixed—were it not liable to the various complications to which we have already alluded, then, indeed, the treatment were easy, and the cure certain. But it is not always the case: various co-existing affections complicate the treatment, and even forbid for a time the employment of chalybeates; besides, there are individual constitutions so intolerant of iron, so peculiarly affected by it, that we are compelled altogether to forego the administration of this useful remedy. We occasionally, also, meet with patients who cannot endure it, except in quantities too small to effect a cure; we are, in consequence, sometimes compelled by necessity to look around for a substitute, and the most efficient one which I have been enabled to discover is bismuth. Under the influence of this metal I have seen gradual and satisfactory recoveries take place in persons whose idiosyncrasy forbade the use of iron. I must not omit to mention the marked utility of cinchona and its salts, and of the carbonate of ammonia. Many bitter vegetable tonics, also, are productive of benefit; but I place more reliance on bismuth, carbonate of ammonia, and the salts of Peruvian bark, than on any of the other substitutes for iron which are usually prescribed. The injurious effects produced by iron are throbbing and pulsation of the vessels of the head, headach, vertigo, and sometimes epistaxis. In one case which lately fell under my notice it produced all the symptoms of intoxication; in another, though given in moderate doses, it caused a delirium which did not subside until the third day. Its tendency is also to produce acceleration of the pulse, heat of skin, and febrile excitement. In a few instances I have observed a well-characterized periodic fever to have resulted from its excessive administration.

There is another ill effect which iron is apt to occasion,—constipation of the bowels; this itself is one of the most uniform symptoms of chlorosis; it is, however, augmented by the ferruginous treatment. Hence arises the important practical rule of thoroughly evacuating the bowels, and of completely allaying intestinal irritation, as a preliminary step to the administration of iron; and of combining with it, during the whole progress of the treatment, such mild aperients as are best suited to the individual constitution, and best calculated to maintain a sufficient and regular action of the bowels.

The mode of administering iron is not unimportant. There is none superior to that of drinking the natural waters at a chalybeate spa; its distance enhances its value, because it involves the necessity of travelling, of change of air, climate, scenery, and associations; and the more the patient enjoys travelling, the more exhilarating will it be to the spirits, and the more effective will the remedy prove. Of all the distant spas, I know not one more generally efficacious than the Laugen-Schwalbach, in Nassau. There are many, however, for whom the weakest of these springs is too powerful; for such, a water less strongly impregnated with the mineral should be selected. Domestic or pecuniary circumstances, and oftentimes the actual condition of the patient, will preclude the adoption of this remedy; so that, for the many, the treatment must be conducted without removal from the paternal roof. To the labours of the

chemist we are indebted for several excellent new forms in which this mineral may be exhibited; nor is this without its value, for the preparation which agrees best with one constitution does not accord equally well with another. There is also considerable variety in their effects; the muriated tincture, for example, produces on the stomach, bowels, and kidneys, an action far different from that of the subcarbonate or the sulphate; and so of the other preparations. Besides, in a disease which generally requires for its cure a prolonged course, it is no small advantage both to vary the preparation, and to be enabled to administer it in a palatable form. The acetated tincture of iron, a formula for which we are indebted to the late Dr. Percival, of this city, is, when carefully prepared and well preserved, a valuable medicine; given in asses' milk, or in cow's milk divested of its curd, it may be easily taken, and long persevered in.

The wine of iron, an old preparation, is one sometimes to be preferred, and may be given in the same manner as the acetated tincture. It is mild in its action, and very suitable for children. The wine of iron and rhubarb is, in many instances, a compound productive of excellent effects. The combinations of iron with ammonia are extremely useful; ammonia forms an important adjunct in the treatment of many cases of this disease, particularly those which are characterized by distressing coldness of the extremities. Mr. Bewley's effervescing chalybeate is a very eligible preparation, and applicable to many cases; impregnated as it is with fixed air, it is grateful both to the palate and to the stomach. The following formula I have also found suitable to many cases; water of the citrate of ammonia, three drachms; water, six drachms; syrup, a drachm; citrate of iron and quinine, from one to three grains:—mix, for a draught to be taken twice or thrice daily.

In both chlorosis and anæmia, I have observed that the treatment has been rendered more certainly, and more speedily effective, by administering iron in conjunction with Peruvian bark and the salts derived from it. Hence arises the value of the triple salt just named; hence also the efficacy of the aromatic iron mixture, which, when united in equal proportions with Griffith's mixture, constitutes a very useful compound. I have often prescribed—and I think with excellent results—bark, iron, and ammonia, conjointly in the following manner:—Decoction of Peruvian bark, ten drachms; tincture of bitter orange peel, one drachm; syrup of ginger, one drachm; bicarbonate of ammonia, fifteen grains. Mix. To be taken two, three, or four times daily, in effervescence, with half an ounce of lemon-juice. The compound iron pill, so prepared as to insure its solubility in the stomach, and repeated in sufficient doses three or four times daily, with the addition of about half a grain of sulphate of quinine—which, though an unchemical formula, increases much the efficacy of the compound—forms one of the most generally and certainly effective modes of administering iron. In pill it is less likely to produce headache, than in solution; and for those who can with facility swallow pills, this mode of introducing iron into the system is at once more easy, and admits, without causing disgust, of being longer continued. The saccharine proto-carbonate, diffused in a vegetable bitter, is also an excellent chalybeate. In cases which require a mild aperient, in co-operation with the chalybeate, I have found the following powders particularly useful:—Bicarbonate of soda, fifteen grains; tartaric acid, ten grains; dried sulphate of iron, from one to five grains; powdered white sugar, half a drachm. This powder should be kept in a dry place, dissolved in a wine-glassful of water, and swallowed whilst effervescing. These powders I have been in the habit of prescribing for the last ten years; they were first prepared for me by the late Mr. Fergusson of Kildare-street. I saw lately in a periodical a good formula for this powder, and very similar to the one now given. As a general rule—to which, however, there are some exceptions—iron should be given in small doses. Some of the natural chalybeate springs, which possess remarkable restorative properties, hold extremely

minute quantities of iron in solution—a hint derived from nature, which we may often advantageously adopt.

The effect of iron in changing the colour of the fæces is so well known that it is unnecessary to dwell upon it; it is also capable of producing an alteration in the aspect and properties of the urine. In proportion as the amount of red corpuscles in the blood is increased by the use of iron, change of air, or other remedies of a tonic nature, so is the quantity of urea and uric acid in the urine augmented. If the chalybeate treatment be too long persevered in, it may lead to and establish a condition of the system directly the reverse of that for which it was originally prescribed. Some time since I saw a young lady, whom, several months previously, I had treated for distinctly characterized and extreme chlorosis. In the interim she had gone to the country, had travelled, and had persevered in the chalybeate treatment for many weeks after the chlorotic symptoms had disappeared. When I saw her, I found her in a totally opposite state, complaining of flushings, headache, red pimples, and a deeply florid colour of the face. Such were the symptoms, which now troubled her far more than her former death-like pallor, and for which she more anxiously sought a remedy. The transition, in her case, was striking: she had been chlorotic, she was now hyperæmic; the red corpuscles, which had been minus, were now become plus. Of this transition I have met with several well-marked instances. A change having taken place in the condition of the blood, the treatment should likewise be changed, since the remedies necessary to ameliorate the condition of the blood in chlorosis, if too long persevered in, may originate an opposite and equally injurious state of the system. The truth of this remark is exemplified in those individuals who, by profuse hæmorrhage, are reduced to the chlorotic state. In many of these instances (in females, from uterine hæmorrhage; in males from long-continued hæmorrhoidal bleeding; and in both, from profuse epistaxis) the blood is so thinned that iron becomes the efficient remedy; but if continued too long, hæmorrhage is reproduced.

Having dwelt upon the effects of iron, and upon some of the formulæ for its administration, the inquiry suggests itself, do we possess any medicine capable of diminishing the amount of red corpuscles, when in excess, of equal efficacy with iron (whatever be its mode of action) in augmenting their quantity when deficient? Can we, in fact, take away from the richness of the blood with the same certainty that we can add to it? Obviously by bleeding, abstemiousness, and evacuations, the whole mass of the blood may be attenuated and impoverished: by these means, however, the blood is not only deprived of its red corpuscles, but all its constituents are wasted, and the object of diminishing the proportion of red corpuscles alone is not attained. Now this is a very interesting inquiry, and merits the fullest consideration. I shall merely touch upon it at present, and reserve more extended observations respecting it until we shall have spoken of the various forms of hæmorrhage. I cannot, however, avoid noticing some remarks which have been made on this subject by Dr. Freke, the clinical clerk to our medical wards, to whom I am indebted for much valuable aid in our researches in Stevens' Hospital, and whose accurate and extensive knowledge of organic chemistry is of great value in the investigation of the phenomena of disease, and its treatment.

In the year 1843, Dr. Freke published in the *Medical Times* the following inquiries:—"Would it not, then, be of importance if any means could be suggested whereby the red globules alone might be diminished, while the other constituents of the blood remained unaffected? Could this be accomplished by the hydro-sulphuret of ammonia?" He then proceeds to express his belief in the twofold possibility that such end might be effected, and that the hydro-sulphuret of ammonia might be possessed of the power of depriving the red globules of an essential constituent, "appropriating to itself a portion of that iron which would otherwise have contributed to the formation of the red globules." His grounds for such belief were, conjointly, the known affinity between iron and sulphur, the observed effects of

hydro-sulphuret of ammonia on the economy, and the supposed function of iron in the globules. In the last number of the same periodical appeared an article, headed "Researches on the Human Blood," by M. Bonnet, of Lyons, the concluding paragraph of which is as follows:—"M. Bonnet has further remarked that the hydro-sulphuret of ammonia destroys the globules completely, and deprives the blood of the faculty of assuming the bright scarlet colour of arterialization." Thus the suggestion put forward by Dr. Freke three years ago has been in a measure confirmed by the recent researches of M. Bonnet. This important practical inquiry requires further investigation; it may lead to valuable results. Whether hydro-sulphuret of ammonia acts primarily on the nervous system, as a sedative poison, or its direct effect be to dearterialize the blood, still, as a medicine, given in well-regulated doses, it may yet be found to possess curative properties.

In the second number of the *Dublin Medical Journal*, May, 1832, a case of disease of the heart was published, at my request, by my late friend Dr. Newton, in which the hydro-sulphuret of ammonia having been administered, the heart's action was reduced to forty-eight in the minute, with an abatement of all the urgent symptoms. In other cases, too, the influence of this medicinæ upon the heart and pulse were very remarkable. I was led to adopt this practice by the accounts given of it by Dr. Rollo, in his work on "Diabetes." I may further observe, that I have been for many years in the habit of prescribing the hydro-sulphuret of lime in the treatment of diseases of the skin. I have employed it internally, in doses of from ten to thirty drops, sufficiently diluted; and externally, in the form of vapour, of lotion, and of liniment. I have reason to speak very favourably of its effects, more especially in those cases in which, from appearances at least, we should be induced to expect an excess of the red corpuscles. Might not its action be similar to that of the hydro-sulphuret of ammonia?—and might not this investigation, if fully carried out, throw a clearer light upon the manner in which the sulphureous waters of Lucan, Harrogate, Aix-la-Chapelle, &c., and the various preparations of sulphur, influence the animal economy. The inquiry is one of interest, and involves the consideration of the treatment of a large proportion of cutaneous affections.

Before dismissing the subject of chlorosis we must notice the opinion entertained by some, that there is a close relation between the functions of the great sympathetic nerve and the symptoms of chlorosis. There are, undoubtedly, strong grounds for the opinion. The ganglionic system of nerves, termed the sympathetic, exercises so paramount an influence over digestion, absorption, deposition, secretion, circulation, respiration, and reproduction, that we cannot but conclude that many of the phenomena of chlorosis are traceable to a primary derangement in the function of this important and widely distributed nerve. I find that Dr. Hill has made some remarks on this subject, and written a sketch of the anatomy and functions of the sympathetic nerve, and its intimate connexion with the essential symptoms of chlorosis, which, when completed, shall be laid before the profession. We have noted, and have on record, a large number of cases, both of chlorosis and of hæmorrhage, in which the blood has been carefully examined; these, in a condensed form, shall be given after the subject of hæmorrhage shall have been treated of.

To Dr. Hill I am deeply indebted for his energetic co-operation in all these investigations: without the aid of his talents, industry, and perseverance, I could never have prosecuted these inquiries.

It is to be regretted that hitherto our investigations have been restricted to venous blood, the opportunities of examining arterial blood being rare indeed.

In the use I have made of the term *anæmia*, I wish it to be understood that it is intended to imply a diminution in the density of the blood, with pallor and debility, without any reference to its quantity, which may be either augmented or diminished.

## Hospital Reports.

### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

ANOMALOUS CASE CONSIDERED BY SOME TO HAVE BEEN MALIGNANT MEASLES, BY OTHERS THE PECULIAR BLOOD DISEASE WHICH LATELY PREVAILED IN DUBLIN.

[Reported by Mr. YEO, Resident Clinical Pupil.]

PATRICK CUNNINGHAM, a policeman, æt. 22, was admitted under Professor McDowel's care, January 31st. The constable in charge gave the following account of him:— He had always been a strong healthy man, but was of a sluggish disposition, and did not like taking exercise. He always had the character of being temperate. On the night of the 29th, he went on duty in perfect health, and came off duty at two A.M. on Wednesday morning without making any complaint. An hour afterwards, he complained of getting chilled, and feeling a great pain in his head and chest, he vomited a few mouthfuls of fluid, and said he felt very cold and weak, shortly after he complained of pain in all his limbs. Dr. Nedley was sent for, and saw him at about one o'clock P.M., and ordered him calomel and opium, and a blister over his heart. He had no more vomiting during the day. At about three o'clock P.M., his face began to change colour, some dark spots appearing on it, and gradually growing larger; next his legs became discoloured, and then his arms and trunk. At eleven P.M. he "took a bad turn" and became extremely weak, and was removed to the hospital at two A.M. on Thursday 31st.

On admission, he was cold, and complained of great pain in his head, chest, and extremities, and said he felt "perished." His intellect was perfectly clear, but he seemed frightened and restless, moving from side to side in the bed. The entire surface of his body was covered with dark purple blotches of various sizes, his nose and lips were perfectly black, a large dark purple patch occupied each cheek and his forehead; the outline of these blotches was distinct and well defined, and exceedingly irregular, looking like so many small maps sketched out on the surface of his body with some dark purple stain. The pulse at the wrist could not be felt. The heart beat so irregularly and rapidly that it was impossible to count its contractions. His tongue was dark blue, covered on the upper surface with a dirty moist fur; the vomiting had stopped; he had no motion from his bowels.

He had no pain or retraction at the back of his neck, all the spinal muscles seemed soft and natural.

The blotches increased in size, and became confluent on the face and extremities, leaving here and there a few irregular spots of skin which were of natural colour. Stimulants were freely given, but he died at six A.M., or twenty-seven hours after the commencement of the attack.

*Autopsy.*—On making an incision through the scalp, a great quantity of dark blood flowed from the veins; the dura mater was quite healthy; the sinuses filled with black blood; the cavity of the arachnoid contained no fluid; the entire of that membrane was beautifully clear and transparent; no sign of lymph at any part; no fluid in the sub-arachnoid spaces; the substance of the brain healthy throughout. The meninges of the spinal cord were all perfectly healthy; no serous effusion, or the slightest appearance of lymph; the posterior spinal artery was filled with dark blood and looked large; the spinal cord was perfectly healthy.

The pleuræ were adherent throughout, so as to cause much difficulty in the removal of the lungs, there was about two ounces of fluid at the base of the right lung, hemmed in by the adhesions. The lungs were in a state of intense hypostatic congestion, but crepitant throughout; no other evidence of any pulmonary disease beyond extreme congestion of the bronchial membrane.

The pericardium contained about an ounce and a half of

fluid, and also a small body of cartilaginous consistence, floating free in the cavity; on the front of the heart there were some removable white spots, but no sign of any adhesion or lodgment of the body in any one place. The heart large, nearly empty; a very small amount of fluid blood in the ventricles. The mitral and aortic valves quite healthy.

Liver congested, healthy in appearance, seventy-six ounces.

Kidneys slightly enlarged and congested, right, five and a half ounces; left, five ounces.

Supra renal capsules, enlarged, and perfectly black in colour.

Spleen, small, hard, and dense, seven ounces.

Stomach and entire of intestinal tract quite healthy.

Bladder, healthy, containing some clear urine, which, when tested, was found not to be albuminous.

In twenty-eight hours after death the body completely lost the dark congested appearance which it had presented, and became *vivid red*. The eruption remained well developed.

Professor McDowel detailed this case at a recent meeting of the Pathological Society. He said that some had regarded this disease, of which ten or twelve instances had already occurred, as an example of malignant fever, and others as a modification of measles. He saw no reason, however, for adopting either view, and was disposed to regard the disease as a modification of the cholera poison. Cholera, he observed, was essentially a hæmorrhœa, the serum of the blood being poured out into the gastro-intestinal cavity, whilst in this case there was a true hæmorrhœa, the blood (not its serum only) being poured out into the substance of the skin; and, just as in cholera, death was not due merely to the amount of serum lost, so here the cutaneous hæmorrhage was not the direct cause of death; but, like the serous hæmorrhage of cholera, was but the evidence of a morbid condition of the blood.

In this disease, which he said might be termed "petechia maligna," there was, as in cholera, profound depression of the vital powers, and rapid nervous exhaustion. In both diseases the mind remained unaffected, and in both the principal morbid changes consisted in more or less intense congestion of internal organs, especially of the lungs.

Examples of this "petechia maligna" had occurred before the outbreak of cholera last year, and the disease had reappeared on the disappearance of cholera, and hence Dr. McDowel considered it possible that some modification of the poison, whether telluric or atmospheric, which developed cholera, might have produced this equally fatal disease. A dark purple eruption had been recently observed in some cases of cerebro-spinal arachnitis, but it differed somewhat from that in the case above detailed. In the former dark serum was effused beneath the cuticle, and produced raised vesicles as occurs in gangrene; in the latter the blood was found effused into the cutis vera, and produced no elevation of the surface.

A REMARKABLE CASE OF MALIGNANT DISEASE OF THE LIVER, IN WHICH THERE WAS ALSO A MOST UNUSUAL CONDITION OF THE HEART.

#### Under the Care of Dr. GORDON.

A labourer, 50 years of age, came up from the county Westmeath, for admission, on the 1st of January. He was a strong, healthy-looking man, said he had been about two months uncomfortably from weight and uneasiness in his right side, and latterly was losing his strength, and his appetite failing; the development in the right side of the abdomen of a hard irregular tumour, with depressed centre, growing apparently from the surface of the liver, and of two smaller nodules immediately adjoining, rendered easy the diagnosis of Farre's tubercle of the liver.

Up to the period of his admission, and for a full week afterwards, the symptoms of this formidable disease were in abeyance, and caused but little distress.

On the 9th of January he began to suffer from vomiting, constipation, and pain in the abdomen.

On the 11th, the bowels had been freely evacuated, and the urine was secreted in normal quantity, but the irritability of the stomach continued, and from this time until his death, on the 31st, he was never altogether free from those two distressing symptoms, severe pain in the epigastric region, and either vomiting or inclination to do so.

The liver commenced now rapidly to enlarge, and almost daily there was an appreciable increase in size forwards of the irregular growth and of the entire organ into the cavity of the abdomen.

On the 21st, he began to complain of intense dragging pain in the belly, quite different from the sickening pain which he before complained of. This was doubtless caused by the rapidly-induced tension of the walls of the abdomen. About this time some new symptoms presented themselves—the lower half of the body became anasarctous, the urine was very deficient in quantity, and loaded with lithate of ammonia, and he began to suffer from palpitation. No disease of the heart could be detected.

The liver continued to increase in size with immense rapidity.

On the morning of the 29th, he was found in a state of complete collapse, cold, covered with profuse cold perspiration, pulseless, complaining of intense pain in the right side; the heart's action could not be felt, and was scarcely audible. He was supposed to be suffering from hepatic apoplexy. He was with difficulty recovered from this collapse.

On the 30th he was very weak, sinking fast. The walls of the abdomen, where he had been rubbing some iodized mercurial ointment, were becoming gangrenous. He died on the 31st. There was no jaundice at any time, but latterly he had the *jaune terreuse* hue so usual in cirrhosis of the liver.

*Post-mortem Examination.*—The liver was enormously increased in size, weighing twenty-four pounds. It had on the upper and anterior surface a large cancerous tubercle, with the depressed centre and corrugated margin. Some others over other parts of its surface, and numerous cancerous tumours were developed through its substance.

The collapse of the 29th instant was caused by a rent of the peritoneum on the right lobe. It was in a perpendicular direction, about four inches in extent. Adjoining the rent the serous membrane was now detached by a subserous effusion of blood. There was but a small quantity of blood in the cavity of the peritoneum, so that the collapse was, in all probability, caused as much by the actual rent as by the loss of blood. This latter was to so small an extent, that it must have been immaterial but for his reduced condition, and the changes which had taken place in the condition of the heart.

There was an extensive development of small cancerous tubercles through all the peritoneum, and over the pulmonary pleura.

The condition of the heart was very remarkable, Dr. Gordon observed in his clinical observations on the case that he had seen but one case exactly similar, and this occurred many years ago under his own immediate observation in the Whitworth Hospital; the case is published by Mr. Adams in the Pathological reports, vide *Dublin Medical Journal*, vol. 19, p. 322. The heart is still preserved in the Richmond Hospital Museum, and retains the shape and appearances which it then presented. In the present instance the heart was quite folded up, the ventricles, particularly the right, being quite compressed and flattened, while at the same time the wall of the ventricle was pushed inwards on itself, so that if a sharp instrument were driven through the ventricle at its external third, it would pass through the wall four times, or in four places. This condition was evidently of considerable duration, for where the ventricular walls were so compressed there was, as in the case published by Mr. Adams, a parboiled appearance, and also a gelatinous effusion, showing that they had been in contact for a long time.

The heart lay completely horizontal, the right ventricle of course quite empty, and the left nearly so. This condition of the heart was in all probability purely mechanical,

produced by an emphysematous condition of the lung above and the over distended state of the abdomen below; the symptoms which belonged to it were, the intermitting pulse, the imperceptible action of the heart, and its feeble sounds, and the gangrenous condition of the walls of the abdomen, the part in which, in the present instance, the capillary circulation was carried on at the most disadvantage.

## Reviews.

**SPHYGMOGRAPHIC OBSERVATIONS ON THE PULSE OF TYPHUS.** By THOMAS WRIGLEY GRIMSHAW A.B., M.B., L.K.Q.C.P.I., one of the Physicians to Cork-street Hospital, &c. Dublin: Falconer, 1867. Pp. 13.

IN this interesting monograph Dr. Grimshaw gives us the result of his application of the sphygmograph to the study of the pulse of typhus fever. Dr. Grimshaw has already shown much ability in his efforts to extend the application of methods of exact investigation to the study of fever, and we have in the pamphlet now before us another proof of the zeal and perseverance with which he pursues the path of scientific medicine. Dr. Grimshaw can at any rate say with truth that his observations were not hastily made, nor from insufficient data. For he tells us:—

“The observations upon which my remarks are founded were nearly all taken in Cork-street Hospital, the majority of the patients observed being under my own care, but many of them under that of my colleagues, Drs. Kennedy and Mason, to whom I have to return my best thanks for the facilities they have always afforded me in the pursuit of scientific enquiry. I followed about sixty cases throughout the course of their disease, the observations upon which were checked by many casual ones upon other cases. At the time the sphygmograms were taken, notes were also taken of the sensations conveyed by the pulse to the finger; the temperature in the axilla and rate of respiration were recorded as well as the other conditions of the patient. Altogether, about 3000 observations of pulse, respiration, and temperature, have been made by me, which I think must be considered sufficient foundation for the foregoing remarks. I hope they will be of interest to the profession, and eventually add, in some degree at least, to our knowledge of the symptomatology and treatment of typhus fever.”

In this hope we fully coincide with Dr. Grimshaw; but we are bound to express our opinion that the sphygmograph will require great improvement before it can be of any use for practical purposes. At best, it appears to us, that it can only be regarded as affording a measure of the rhythm of the pulse, but it gives no indication of its force, its tone and its volume, which, in our opinion, can only be ascertained by the *tactus eruditus* of the physician, and which no piece of mechanism however ingenious, can replace. Dr. Grimshaw, however, frankly admits this. “What practical use,” he asks, “can we make of the information offered us by the sphygmograph in typhus fever? At present, not *very* much, excepting the advantage we derive from a more accurate and definite knowledge of the general symptoms of the disease,” p. 9. Dr. Grimshaw has, in our opinion, produced a very creditable essay on this subject, and we commend it cordially to our readers.

**TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF LONDON.** Vol. VIII, for the year 1866, with a list of Officers, Fellows, &c. Pp. 404. London: Longmans, 1867.

THE present Transactions of the Obstetrical Society form a more bulky volume than those of any previous year, and indicate alike the zeal of the members and the increasing resources of the Society, which now numbers 500 Fellows, possesses a well-stocked library, and enjoys an annual surplus in money which is devoted to the advancement of obstetric science. The meetings of the Society are so regularly recorded in the medical journals that it is unnecessary to enter into a description of the topics described and discussed, and we need only observe that the volume, as usual, is very elegantly got up; that the illustrations are numerous and well-executed, and that the whole presents a faithful picture of a year's conscientious work in obstetric medicine and surgery.

### NEW AND OLD MEDICINES IN THE BRITISH PHARMACOPŒIA OF 1867.

IF any fault is to be found with the forthcoming British Pharmacopœia in reference to the number of substances it contains, the accusation would lie in the direction of redundancy rather than of deficiency. Nearly all the preparations described in the Pharmacopœia of 1864 are retained, the few exceptions being the catechu nigrum, cocculus, the spiritus pyroxylicus rectificatus (methylated spirit), and the unguentum cocculi, which four are expunged. On the other hand, many have been added to the list, and some which existed in former Pharmacopœias, have been restored. In the present day, when the merits of all drugs are keenly criticized and called in question, when many of our most approved medicines are condemned by some authorities as either useless or noxious, and when the efficacy of drugs is by some, and these no mean guides, denied almost altogether, one would perhaps rather expect that the list of substances in our medical *armamentarium* would be considerably reduced; but the framers of the Pharmacopœia probably thought that the public, after all, notwithstanding the dogmas of the homœopaths, and the hydropaths, and the mesmerists, and the kinesiopaths, *et hoc genus omne*, retained their faith in medicaments for the cure of disease, and accordingly a long and formidable array of substances, simple and compound, still figures as the constitution of our national *Materia Medica*.

We have the usual formulæ for pills, and powders, and tinctures, and infusions, and decoctions, and liniments, and ointments, and we find, in addition to these, that preparations are introduced having glycerine for their base, and which are called, respectively, glycerinum acidi carbolici, g. acidi gallici, g. acidi tannici, g. amyli, and g. boracis, all which preparations will probably be found useful as a means of introducing the respective drugs into the system

in a cleanly and agreeable manner. The combination of glycerine with various medicinal bodies has long been in use in France, where the preparations are called glyceroles. Whether used externally or internally, glycerine is a very convenient medium for combination with more active substances.

Another series of preparations, now introduced for the first time, is that of the *vapors*, those enumerated being the vapours of hydrocyanic acid, of chlorine, of conia, of creasote, and of iodine. Of the efficacy of these preparations we cannot write with much confidence, and as they are directed to be inhaled, we should recommend that when employed great care should be exercised. The vapour of prussic acid, for instance, must be used with caution, although it is true that only ten to fifteen minims are directed to be given at a time, with a drachm of water; and as to the vapours of chlorine and iodine, they are apt to produce great irritation, and may, perhaps, do more harm than good in many cases.

The lozenges, or trochisci, which appeared in the Pharmacopœia of 1864, have received an addition to their number, the novelties being the lozenges of ferrum redactum, of ipecacuan, of chlorate of potash, and of bicarbonate of soda, and all these will be found useful adjuncts to the list, being especially well adapted for the use of children.

Two metals make their appearance for the first time, namely cadmium and cerium, the preparations of which are respectively, the iodide of cadmium and the ointment of the iodide of cadmium, and the oxalate of cerium. The iodide of cadmium, in the form of ointment, is employed to promote absorption in cases of indurations and is similar in its action to the iodide of potassium; the oxalate of cerium, which is a tasteless powder and insoluble in water, has been recommended in the vomiting of pregnancy and in other forms of sickness not depending on organic disease of the stomach, and the dose is stated in the Pharmacopœia to be from one to two grains, although perhaps a larger dose might be given.

Our old friends the Black Draught and the Black Wash both make their appearance also for the first time, and in these days of medical scepticism it may be interesting to know that the former still consists of an adequate amount of senna and salts, with the more agreeable adjuncts of extract of liquorice and compound tincture of cardamoms.

Among other novelties are the carbohc acid, which is directed to be used as a *glycerinum*, and is said to be efficacious in some cutaneous affections; the sulphate of atropia and the solution of the same, the latter being an addition which will be welcomed by ophthalmic surgeons as affording a solution of atropia of definite strength, the carbonate of bismuth, and the solution of bismuth and citrate of ammonia, both useful in certain dyspeptic affections; an effervescent solution of lithia; a solution of carbonate of

magnesia, which is probably the same composition as that known under the name of Dinneford's Magnesia; the oil of theobroma, a concrete oil, with a smell resembling that of chocolate, and known as cacao butter, used in the form of suppository, together with tannic acid, mercury, morphia, and acetate of lead with opium; the calabar bean, under the name of *physostigmatis faba*, and *extractum physostigmatis*, the dose of which latter is stated to be from the one-sixteenth to one-fourth of a grain when used internally; the compound tincture of chloroform, which consists of chloroform, rectified spirit, and compound tincture of cardamoms; sumbul root, employed in the form of tincture as a stimulant and antispasmodic; the root of *veratrum viride*, or green hellebore, a very powerful drug, which has been highly extolled, especially in America, as a sedative in inflammatory diseases, and in gout and rheumatism, used also in the form of tincture, the dose being from five to twenty minims.

Among old acquaintances which figured in former Pharmacopœias, but were omitted in that of 1864, many practitioners will be glad to welcome back the acetum cantharidis, and the acetum and oxymel scillæ; canella alba also reappears, though its merits are not very remarkable, and the same observation may be made of the decoction ulpic, or decoction of elm bark, and the extract of lettuce; the essences of aniseed and peppermint are restored, and are really useful formulæ: the same may be said of the liquor hydrargyric perchloridi, the compound infusion of gentian, the pilula aloes et ferri, the mistura spiritus vini gallici; the iodide of lead and its ointment have likewise been re-instated, and we think deservedly so, as the ointment may be employed without discolouring the skin, an inconvenience which attends the use of the iodine ointment; radix pyrethre, the old pellitory root, and the syrup rhaunic, or familiar syrup of buckthorn, have been somewhat unnecessarily rescued from oblivion, and the nauseous sulphate of soda, or glauber's salt, is also restored, together with the spiritus ammoniaë fetidus, an equally nauseous drug, though perhaps efficacious in certain instances.

#### USE OF STIMULANTS IN POOR-LAW MEDICAL RELIEF.

We observe with regret that an unconsidered proposal to save money by refusing stimulants for the treatment of disease in workhouses has been jumped at by several Boards of Guardians with an alacrity seldom displayed in respect of charges involving any expenditure. On the 10th of December last, Mr. James Haughton, whose name is familiar in connection with Total Abstinence, moved at the North Dublin Union that the abolition of stimulants in the treatment of disease be brought under the special attention of the Medical Officers of the Union. Subsequently the matter was taken up at Cork, and a committee appointed to take it into consideration. Now, we observe that the

Holyhead Guardians, who, *en passant*, we may mention, have acquired celebrity by their obstinacy and obstructiveness in sanitary matters, have decided that stimulants shall not be ordered by their Medical Officer without previous communication with the relieving officer, who, in a published correspondence, warns the Guardians of the hardship and danger to life which such a system entails on the poor. We know that differences do exist in the minds of medical men as to the relative value of alcohol in disease; but we have never heard of any one whose opinion was worthy of complete confidence who denied the necessity for its use in certain cases, while many of the highest authorities place the greatest confidence in its use. The entire movement seems to have originated with Dr. Nicolls of Longford, and Mr. James Haughton, neither of whom, though doubtless influenced by the best intentions, we venture to say, can confer a conclusive authority for its adoption, and we are not aware that their opinion has been confirmed by any person of note, except Professor Gairdner, who by no means advocates the universal exclusion of stimulants. We hardly even think that the matter has reached a stage to justify an investigation into the statements of these gentlemen, and we cannot too strongly condemn Guardians who declare their readiness to incur any risk of life or limb to the paupers under their charge for the sake of an experiment which saves money. We don't think it necessary to go into details, but we append a few extracts from such evidence as the teetotallers are able to bring, which appear to us utterly insignificant, as compared with the vast experience of the entire of the profession:—

At a meeting of the Guardians of Longford Union, the following report was submitted by Dr. Nicolls:—

"MY LORDS AND GENTLEMEN—I beg to submit to you a report of the cases of cholera treated by me in the cholera wards, during the recent visitation of that disease to this town. The first cases were admitted on the 17th December, 1866, and the latest discharged on the 19th January, 1867. There were—extern cases, 20, intern, 2—22. Of those there recovered 15, died, 7—22; being at the rate of about—recovery 68; mortality 32 per 100.

"This contrasts favourably with the result of the cholera of 1849, when 77 cases were treated in the wards under my care, with the following results:—Recovered, 12; died, 65;—77. Of the first 50 cases there were—recoveries, 3; deaths, 47;—50; or, recoveries, 6; deaths 94 per 100. Those were treated with a liberal allowance of alcoholic stimulants and warmth, both internally and externally. I felt dissatisfied with this result, and determined to change the mode of treatment, which I did in the following 27 cases; withdrew alcoholic stimulants, and discontinued heat internally and externally. Immediately the improvement became visible, as the result was—recoveries, 18; deaths, 9; or, recoveries, 67; deaths 33 per 100. This convinced me that the former treatment was erroneous, and the latter correct and rational, and from that time to this I have ceased to use alcoholic stimulants in the treatment of contagious or infectious diseases, such as are usually admitted into fever hospitals and cholera wards. The difference in the death-rate in the former attack of cholera where alcoholic stimulants were used, and the latter where they were excluded, is very large, in the former 94, in the latter 32 per 100. It may be said that the cholera latterly was not so malignant as formerly, but it is generally considered by medical men and clergymen that in proportion to the number of cases, the death-rate in this and the neighbouring towns during the recent visitation was higher than in the former."

In a private note, Dr. Nicolls writes:—

"In addition to the cases treated in the cholera wards, I had six cases amongst the inhabitants of the town, every one of whom recovered—so that, out of the 28 cases I treated, there were 21 recoveries to 7 deaths. It is true the number is small, but it bears out the change of treatment I adopted in 1849."

The following is an address delivered by Mr. James Haughton:—

"Gentlemen, I have felt it to be my duty to bring the annual

report of the medical officers of the Longford Union under your notice.

"FEVER HOSPITAL.

"Remained, 0; admitted—interns, 10; externs, 41; 51—of whom 43 recovered, six died, and two remained. Of the deaths, one was a girl, aged ten years, who, when recovering from fever, was attacked with pneumonia (inflammation of the lungs), of which she died; one was a girl aged 18 years, she was recovering from fever when diarrhoea set in, of which she died; one was a woman, aged thirty-three, a wandering mendicant, brought in speechless and unconscious; she died thirty six hours after her admission. There were also three men of very intemperate habits—one was suffering from hectic and diarrhoea, the result of a chronic abscess; one was a rambling tinker, speechless and unconscious when admitted; another, a pensioner, in delirium tremens, of which he died; so that, in reality, there were but two deaths from fever, and those were unconscious and speechless, and died shortly after their admission. I continue the non-alcoholic treatment, which for the last 18 years I have found most successful.

"INFIRMARY.

"Remained, 60; admitted—interns, 491; externs, 272; 823. Recovered, 737; died, 45; remaining, 41;—823. Of the deaths, 13 were children not exceeding three years, and eight between three years and sixty years; twenty-four were sixty years and upwards. Of the cases treated in the infirmary many were serious surgical and midwifery, which all made good recoveries. I beg again most respectfully to direct your attention to the great necessity of having duly educated midwives in the different dispensary districts. I frequently hear of women and children being lost through the ignorance of the ordinary midwives.—I am, my Lords and Gentlemen, yours most obedient.

"S. NICOLLS, M.D., Medical Officer."

"Dr. Nicolls informs us that he continues the non-alcoholic treatment which he has found so successful hitherto. In his report for 1865 he states his practice in these plain words:—'I beg further to state, that this hospital is conducted on vegetarian and temperance principles, not one pound of flesh meat, pint of whisky, or bottle of wine having been used in it for the last fifteen years.' And he informs me that such is still his practice. This non-stimulating treatment of fever, we find by his last report, continues to be most successful. Taking the cases of death in that department, although Dr. Nicolls thinks only two should be placed to its account—the percentage is, nominally, twelve—but really only four. As we have no fever hospital in our union, I will, therefore, compare this result, as I did on a former occasion with the deaths during the past year in Cork-street Fever Hospital. In the report of that hospital for the year ending March 1865, I find that the deaths were over seven and a-half per cent., a proportion which Dr. Kennedy considers favourable, as the number of severe cases was large. It will be thus seen that Dr. Nicolls's practice contrasts favourably with that of as noble and as well managed an hospital as is to be found in these kingdoms. Dr. Kennedy states that the percentage of deaths in it from typhus fever is smaller than in England and Scotland, which he attributes to the different dietic habits of the people in those countries, where, he says:—'They use more malt drink, and much more animal food; and there can be little doubt these habits engender a state of the system very unfavourable indeed for the attack of such a disease as fever.' Dr. Kennedy is not a teetotaller nor a vegetarian; he uses both flesh and alcohol in the cure of disease, so that his testimony in our favour is very valuable indeed. In addition to the foregoing opinion, he says, in the same medical report from which it is taken:—

'Before leaving the question of the rate of mortality in typhus, I would observe on the marked difference which it obtains between the wealthier and the poorer classes, being very much higher in the former than the latter. It is not too much to say that it is three times more fatal amongst the one than the other. In addition, a class of food is in daily use, which has, at least, a tendency to keep the system at too high a standard of health; and when to all this is added the anxiety of mind which the head of a family so often feels as regards his worldly affairs, we need be at little loss in accounting for the much greater mortality in fever which exists amongst the middle and upper classes, when contrasted with their poorer neighbours.'

"The cost per head in the Longford Union is stated to be 2s. 3d. a-week, with us it is 3s. 6d. Favourably as Dr. Nicolls's treatment of fever contrasts with that of hospitals in other parts of the kingdom, the results as regards other

diseases in the Longford Union and in our union are even more striking. Gentlemen, having in February, 1865, gone at some length into this important question before this Board, I shall not now weary you by a repetition of the arguments I then used, or of the many evidences I then brought under your notice from the writings of several eminent physicians, strongly condemnatory of the free use of alcoholic liquors in our hospitals and poor-house infirmaries. On that occasion you passed a resolution, referring the matter to the Poor-law Commissioners, who had the matter investigated, which investigation proved that Dr. Nicolls's statements were fully borne out by facts."

## Notes on Current Topics.

ROYAL SOUTH HANTS INFIRMARY.—An investigation by the Committee of Management of the Royal South Hants Infirmary into some cases of alleged bad surgery has recently taken place. We have received a number of newspaper reports and comments upon the proceedings, but in spite of a diligent perusal have been unable to find amongst them many important facts bearing upon the points at issue. From what would appear on the surface, the profession is in a very unsatisfactory state in the town, and the infirmary, we should fear, not likely to increase its subscription list, by the late investigation. Mr. Scrase, pursuant to notice, brought forward some cases in which he averred there had been bad practice in the infirmary. The first fact that strikes us about them is, that none of these cases are recent. They occurred as far back as 1858 and 1859. Nevertheless, they are now brought forward, and a formal committee of investigation undertakes the inquiry. Such being the case, it might have been anticipated that the inquiry would be conducted with the utmost calmness. We find, however, the strongest excitement prevailing. Every speaker seems to have argued with the warmth of an advocate; even the chairman, who should surely have possessed some of the impartiality of a quasi-judicial functionary, saying, according to a local journal, that "if Mr. Scrase did not *substantiate his charges*, he would go out of the room a *dishonoured man*," adding, that it "was no joke to come there and sit for a long time, and unless the cases were conducted properly, he would shut up the book, and consider he (Mr. Scrase) had failed to prove his assertions." An inquiry carried on in this manner could scarcely result in any good, nor was it likely to give much satisfaction. For the sake of the profession we are glad to record that the committee entirely acquit their staff, and record their best thanks to them. But there are larger issues involved, and we propose, on a future occasion, to revert to them. At present we have certain enquiries of our own going on, pending which we shall reserve some points. We will, however, devote a few lines to a feature of vital importance to the infirmary and to the profession in Southampton. Several years ago an enquiry was made into some alleged mismanagement of that institution, and the very cases recently brought up were then alluded to. At that date it became abundantly clear that there was urgent need of reform in the general management of the institution. The practice of the infirmary was virtually secret—the practitioners of the town not on the staff being excluded from entering it even as visitors. This was condemned by the whole profession, and the several journals agreed upon the necessity of other changes. Now, so far as we have hitherto heard, those changes have not been carried out. Let then the governors address themselves to this wider subject. The very fact of

renewed charges being brought forward argues something wrong in the system under which this becomes possible. Had everything been in a satisfactory condition during all these years would Mr. Scrase have taken upon himself to renew this charge against the staff? Surely there is something else with which he and those who support him are dissatisfied, and this is made a mere stalking-horse. We do not indeed applaud the plan. An attack upon a professional man is to be strongly deprecated, except in the most extreme circumstances. No good can come of it, but much evil may. While, therefore, we rejoice that the reputation of no one has been injured by the decision of the committee, we would urge upon that body the necessity of no longer delaying to march with the times. Seven years ago their Infirmary was one of the closest boroughs in England, an age behind the time. What is it now? Has Reform been even proposed? Have they even now a bill ready? If not, we would advise the Governors to take the matter into their own hands, and elect a new committee of management pledged to reform.

LONDON HOUSES.—In an article respecting the imperfections of the Metropolitan Building Act, the *Daily News* draws attention to two causes of the insalubrity of some London dwellings which ought to be provided against in any future legislation. The first is the growing practice of carrying up houses to such a height in narrow streets, as effectually to cut off all sunshine from the opposite side. In as much as the value of land in London is continually rising, it is not unlikely that this evil may increase to an unexpected extent. But can nothing be done to provide for greater width of thoroughfares? at least, in the suburbs, some regulations might be enforced. The second complaint urged by the *News* is the scandalous practice of speculative builders, who excavate the gravel or other foundation to sell, and then fill up with "made ground," the compound that results from sticking up a board with the inscription "rubbish may be shot here." The emanations from the refuse which forms the foundation of many a pretentious villa must be injurious to the health of the inhabitants, and we should be very glad to see the builders prevented from thus acting.

EDINBURGH HOUSES.—The *Courant* of Edinburgh has commenced a series of revelations of the present condition of the homes of the poor in the northern capital, which cannot fail to do good. Few, besides medical men, are aware of the squalid misery in which, in all our great cities, the poor pass their lives. We sincerely wish the *Edinburgh Courant* God-speed in this useful crusade.

VIVISECTION.—We observe in the March number of *Belgravia*, the magazine recently started by Miss Braddon, a very sensible article on vivisection, by Dr. Scoffern. It is written in so strictly argumentative a manner that no one can possibly object to a single paragraph, as likely to wound the susceptibilities of the French. Everything like indignation is carefully excluded, and even the concluding sentence, which consists of an illustration of how a distinguished hospital surgeon prepared himself in the dissecting room for a difficult and unusual operation, by practising on dead subjects, is toned down to a bare matter of fact—its truth and human interest alone supplying the one sentiment of the paper. It is quite unnecessary for us to give Dr. Scoffern's argument. We do not defend the atrocities

perpetrated under the name of vivisection. On account of its character we hope this common sense statement of Dr. Scoffern's will be translated into French, and widely circulated in France, where we think it would receive the attention it merits.

FEMALE DOCTORS.—The Society of Apothecaries of London has issued a notice that in future no certificate of attendance on lectures will be received unless such lectures have been delivered before the classes of a recognized school of medicine. The lady aspirants for the license must, therefore, abandon their notions, or pass through the course of dissections, &c., in company with students of the other sex—a thing a lady could not be expected to do. The regulation is, in fact, expressly designed to exclude females.

WORSE THAN GREGARINES.—Our readers last week had an opportunity of seeing to what extent the writers of sensational paragraphs may go. A contributor to the *Lancet*, as if in very sport at the alarm already created, has had the audacity to out-Herod Herod. After showing his erudition respecting the *pediculus*, and dwelling on the "ill effects of the artificial practices of adornment, which are supposed to enhance the conventional beauty of the fair sex," he goes on to assert that "many ladies carry about with them in their 'chignons' the seeds of ringworm." Nor is this all, for this remorseless writer adds, "that there is in our markets a novel species of false hair called 'church-yard hair,' consisting "not only of the shafts but the roots also," and obtained, as the name implies, "from the scalp of the dead." We should be glad if this revealer of horrors would inform us whether his budget is yet empty.

PAYMENT OF MEDICAL OFFICERS IN DUBLIN FOR CHOLERA SERVICES.—Our observations last week on certain remarks, which were attributed to a guardian of the North Dublin Union, have elicited from that gentleman a reclamation, which we think it necessary to notice. The phrase of which we complained was:—

"If I desire to entertain my friends frequently, I don't think it necessary to pay *my servants* extra for their attendance, nor do I see why our doctors have any right to claim special payment."

The gentleman declares that he made use of these words in reference to the porter of the Green-street Hospital, and not to the medical men. We beg to observe that the words used occurred in the course of a discussion on the question of payment of the medical officers which was the only business for which the guardians were summoned to consider on that day; and, we cannot conceive, how the question of the porter could have intruded into the matter, unless perhaps that functionary were grouped with the doctors. That the attributed significance was attachable to the gentleman's words, whether it be intended or not, we have the authority of a guardian present for saying that he and others were under the impression that the words were intended to apply to the doctors. We are, however, glad to have elicited the denial of the gentleman to whom the phrase was attributed, and we hope we may accept it as an acknowledgment of the bad taste of such a tone of remark as applied to educated officers of the Union.

In connection with this subject we have to inform our readers that the letter of the Poor-Law Commissioners in favour of the extra remuneration of the medical officers, which appeared in our last, was since under the consideration

of the Board. It was moved by Dr. Brady, that the remuneration be at the rate of three guineas a-week, but we regret to observe that his suggestion was not accepted, and the previous niggardly offer of the Board was affirmed.

Unfortunately the Board, in their policy, cannot obtain credit even for the very limited virtue of economy, because they have not extended their principle to all their officers. While they refused to recognise the services of their dispensary surgeons, they voted not only their thanks, but a more valuable honorarium of £50 to their apothecary, Mr. Tate, whose duties in the cholera epidemic were infinitely less onerous than those of the medical officers. That gentleman received no more than his due, but the vote exclusively to him shows that the parsimony of guardians may relax under peculiar circumstances.

**MEDICAL CHORAL SOCIETY.**—We observe with pleasure a notice of the Medical Choral Society of Dublin, which appears in our advertising columns to-day. The Society inaugurates its existence under very favourable auspices, especially as regards the countenance which it has received from the senior members of the profession and teachers in the Dublin School. Next to strictly professional employment, it is of great importance that students in our profession should enjoy every opportunity of devoting themselves to such desirable pursuits as music, and any amusement which may divert their leisure from the streets ought to be met with the most anxious assistance by those who have the status of the rising generation of the profession at heart. There is, we believe, an ample constituency for a flourishing society, and we can venture to anticipate that its members will be no worse surgeons and physicians, and will certainly be the better gentlemen for their connection with it. It is neither desirable nor possible to make all medical students professional "stews," and they can dilute their professional business with no better ingredient than an evening's glee singing.

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

FRIDAY, FEBRUARY 15, 1867.

Dr. BUTCHER, President of the College, in the Chair.

THE PRESIDENT said that an important question had been submitted to three members of the Society on the last occasion of their meeting—namely, to ascertain the constituents of a salivary calculus. He now called upon those gentlemen to submit their report.

Dr. MAPOTHER read as follows:—

REPORT OF THE COMMITTEE AS TO THE CHEMICAL CONSTITUTION OF THE SALIVARY CALCULUS PRESENTED TO THE SOCIETY BY DR. LEECH.

"One-third of the portion given was heated in the flame of a spirit-lamp, when it blackened, and emitted the burnt-feather smell characteristic of the nitrogenized compounds. Its organic matter was, therefore, presumably, dried mucus. By further heat the mass became white, the carbon being oxidised, and the ash was alkaline from lime. By complete incineration the loss of weight was one-twelfth.

"The inorganic constituents were carbonate of lime and phosphate of lime, respectively, in the proportions of two-thirds and one-third. The quantity being so small, an

exact quantitative determination was not attempted, but the percentage may be roughly stated as follows:—

Carbonate of lime . . . . .	60
Phosphate of lime . . . . .	30
Organic matter (probably mucus) . . . . .	8

"The remaining portion was boiled in distilled water, and the liquor was tested on a white slab with persulphate of iron. No trace of sulphocyanide of potassium appeared."

In another submaxillary calculus which I examined in 1863, there was no carbonate of lime.

The compositions of those analysed by various chemists are as follows:

	Wright.	VonBibra.	Lecanu.
Carbonate of lime . . . . .	81 79 80	13	20
Phosphate of lime . . . . .	4 5 4	38	75
Soluble Salts . . . . .	6 4 5	38	5
Animal matter . . . . .	7 8 8		

Those from the horse contained:

	Lassaigne.	Henry.
Carbonate of lime . . . . .	84	85
Phosphate of lime . . . . .	3	4
Organic matter . . . . .	9	2

No analyst mentions that sulphocyanide of potassium was present, which, even if originally present, would dissolve out in the fluids of the mouth. It will be seen from the above widely diverse analyses, that concretions deposited from saliva differ almost as widely as those formed from urine, at least with regard to the proportions of their constituents.

Dr. Mapother likewise added, that he understood Dr. Jameson possessed two salivary calculi, and perhaps, if he had brought them down with him that evening, he would kindly let the Society see them.

Dr. JAMESON said he had brought the specimens with him, having heard that such a subject would be before the Society. They were two very excellent examples of salivary calculi. One was extracted by himself from their old friend Jerome Morgan. He had been suffering a great deal of distress and inconvenience from a swelling in the sublingual region. He (Dr. Jameson) cut down on it, and extracted this calculus. He had a part of it analysed, but he forgot with what results. The other specimen was also a very beautiful one, and had been extracted from a similar situation under the tongue. There was a regular ball and socket joint formed between the two portions of the calculus. This specimen was given him by Mr. Edward Dillon, the demonstrator, a few days after he (Dr. Jameson) had extracted the calculus from Dr. Morgan's sublingual region.

Dr. LEECH said the calculus he removed had a ball and socket joint also, and likewise a nucleus.

Dr. JAMESON observed that there was a nucleus in the centre of the calculus which he had extracted.

The CHAIRMAN said they had to thank the gentlemen who had made the analysis of Dr. Leech's calculus. The sulpho-cyanide of potassium was not detected, in the first instance, by the gentleman who analysed a very small portion of the calculus. A doubt having been thrown out whether that peculiar salt might not have escaped his observation, a larger portion was kindly given by Dr. Leech, which having been subjected to examination by three most competent analysts, the original analysis was confirmed. The specimens shown by Dr. Jameson were very typical ones. The largest of them did not, however, approximate to the size of that exhibited by Dr. Leech. He had, himself, seen specimens very nearly as large as it. He thought when the calculi arrived at a certain size they were broken by the motion of the tongue, and the ball and socket joint was then formed by the movements of that organ.

TREATMENT OF CERTAIN DISEASES OF BONES AND JOINTS BY THE DEEP INTRODUCTION OF CAUSTIC.

Dr. FREDERICK KIRKPATRICK spoke as follows:—Mr. President, I am anxious to bring under your notice this evening, for the consideration of the members of the Surgical Society, a subject which has for some years engaged

my particular attention—namely, the treatment of diseases of the bones and joints by the deep introduction of caustic, combining and extending its action by means of incision, so as to bore down to the seat of the disease, into the cancellated structure of the articulating extremity of the joint, in the incipient stage of disease, or into the joint itself in the more advanced periods. I do not, sir, by any means wish to make light of those great achievements of conservative surgery which have so interested and engaged the profession of late years, or to utter one word in depreciation of the operations for excision of joints, those difficult and heroic operations which must always be honourably associated with your name. But, sir, the treatment which I have the honour to bring under your notice this evening has been attended with so great a measure of success in my practice, that I feel warranted in pressing it upon the notice of my professional brethren, and in requesting that they will give it a fair trial in their hospital practice. Great numbers of patients afflicted with diseases of the bones and joints are admitted into the North Dublin Union, and of late years I have been enabled to devote myself to the carrying out of this mode of treatment, as I have been relieved from the general charge of the establishment, and have only to visit a few wards set apart for curable surgical diseases.

Sir Benjamin Brodie, in his great work on this subject, states that those diseases originate in the cancellous structure of the bones, and he describes the incipient morbid condition as “a preternaturally vascular state of the bones, the presence of a reddish fluid mixed with medulla in the cancelli, and a deficiency of earthy matter.” I would wish to add to this the further statement, that this diseased condition at its onset commences very near to the surface, and quite accessible to our reach, as it is in general produced by a fall or some external injury. But, sir, nature has so firmly encased those projecting extremities of the joints by means of a firm periosteal membrane, a condensed cellular tissue, and great thickness of the integument, that when matter is formed it never can make a direct exit, but either forces its way into the cavity of the joint, or takes a sinuous and often distant course through the muscles to the surface. Now, Sir Benjamin Brodie further states that this morbid condition which precedes ulceration and abscess is not to be relieved by local remedies, and he says that an opening is not to be made when much substance intervenes, but directs you to wait for thinning to take place.

Notwithstanding this great authority, I am bold, sir, to declare that this is the very time for successful interference on the part of the surgeon. The mode of operation which I propose is simple, and only occupies a few moments. The patient having been placed under chloroform, the deep boring of the diseased articulating extremity is effected by the alternate use of a small strong knife, and a piece of the potassa c. calce slightly pointed and moistened with proof spirit. A funnel-shaped deep hole is formed after a few days, which is attended with very little pain or surrounding inflammation, and if the disease is attacked in the early stage, healing from the bottom takes place with great rapidity, and the disease is often cut short by the single operation. On the other hand, if the softened structure is not sufficiently opened up by one perforation the process is to be repeated in a few days, either using the solid caustic or the potassa c. calce in powder, introduced with a piece of pointed wood. If this is not sufficient, a counter opening must be made at the spot where softening of the bone is indicated. There is no limit to the depth that can be reached in this manner, and in one instance I passed a catheter from one aperture to the other completely through the bone. I will now read for the Society two cases selected on account of the very rapid cures that follow this plan of treatment:—

John Corbet, aged 11 years, of delicate aspect; three of his brothers and sisters had died, and his father had been carried off by cancer at 41 years of age.

For twelve months he had been disabled by disease of the right hip, and had been in two hospitals.

The hip-joint was unaffected, but the great trochanter was tender and manifestly diseased.

A large abscess existed at the back of the thigh towards the inner side.

On the 8th of May I opened the abscess with incision and caustic. During the next month the discharge was so profuse, and the child was so rapidly running down, that I decided on boring the trochanter, notwithstanding the very unfavourable constitution I had to deal with.

On the 15th of June, having made the surface insensible with ether spray, I made an opening and bored the softened structure of the bone fully to the depth of an inch. A round funnel-shaped opening was formed after a few days poulticing, and a free and healthy discharge followed, with an immediate reduction of the flow from the sinus in the thigh. It was only necessary in this case to repeat the caustic once, and on the 15th of July, one month from the application of the caustic, both apertures were perfectly healed. There has been no recurrence of disease in the vicinity of the joint since.

Patrick Howard, a healthy robust man, aged 28, by occupation a cab driver; admitted into hospital with disease of the joint between the first and second phalanx of the middle finger. The finger was red, swollen, and painful, and measured an inch more than the corresponding one of the opposite hand at the centre of its dorsal surface; a fungus protruded with an opening in the middle leading directly into the cavity, from which there was a free discharge. There was lateral motion, distinct grating, and acute pain complained of, and the articulating extremities touched by a probe were found denuded of cartilage.

The history he gave was, that he was bitten by a woman in a street row, and the joint opened seven weeks before admission; that he continued to drive his cab until his hand became so painful and useless that he had to relinquish work and seek admission to hospital.

On the 9th of January he was placed under chloroform; the projecting fungus was destroyed, and the caustic freely entered into the joint; the knife being used, laterally, to facilitate the proceeding. Some of the powdered potassa c. calce was also rubbed into the diseased cavity with a small piece of pointed stick, round which cotton was rolled, so as completely to destroy the diseased membrane lining the joint.

On the 12th the swelling was much abated; skin of the finger pale and wrinkled to the edge of the slough; pain entirely gone.

On the 14th, a clean granulating cavity was exposed, which was dressed from the bottom with dry lint.

On the 20th, healing was so much advanced that adhesive strapping was applied, and on the 26th, the seventeenth day from the introduction of the caustic, he was discharged to his work with a stiff finger, a very small cicatrix marking the surface where the caustic had been so freely applied.

The PRESIDENT said the point laid down was one that would admit, he thought, of discussion. If you can rescue a joint, as Dr. Kirkpatrick had done, either from amputation or excision, that was a complete triumph of conservative surgery, and they all knew well the meaning of that word. Any observation coming from so practical a surgeon must meet with deserved attention. The point raised was one perfectly novel, and it required their careful consideration. If by this treatment early adopted they could rescue a limb from excision or amputation, a great service would be rendered to the patient. Excision had its own class of cases to which it was specially applicable, and the great mistake in the profession was endeavouring to make excision take the place of amputation. It could not do so. If the mode of treatment proposed by Dr. Kirkpatrick was sustained by the test of experience, and shown to be free from the risk of danger to the life or limb of the patient, it would be one of the greatest improvements in surgery which the present century had brought out.

DR. KIRKPATRICK observed that there was no limit to the depth to which they might go with his operation. He had passed a catheter quite through the tibia. He first used the ether spray, then made the incision, and then

passed in the catheter, and after that the opening could be made as large as he pleased. After half an hour the patient suffered no pain. He had a horror of tetanus following, and ever since he commenced this practice he had given a nightly dose of opium until all danger was over.

Mr. COLLIS should not delay the meeting by repeating what the President had said, that this mode of treatment might supplement what seemed to be wanting, both in excision and amputation. These had their proper places, and what was wanted was an early treatment of an early stage of bone disease. Many years ago he was struck by a case under Sir Philip Crampton's care, in which the bones of the carpus were much diseased. He made free and bold incisions, and allowed the inflammatory products to drain from the bones. The result was that the bone cicatrised, and the man recovered and had the perfect use of his wrist. He had seen that man many years afterwards, and he was able to use his hand with perfect freedom. If they studied the situation in which these inflammatory accidents occur, they would find, as a rule, that the part generally inflamed was the dense subcartilaginous layer of bone—the part that lies immediately in contact with the cartilage. As soon as this was inflamed the cancellated structure below became softened and undermined. The products of inflammation found a difficulty in escaping. He had for a good while thought that the proper treatment for this disease would be the trephining of the head of the tibia when the knee was affected. The site of selection was the inner condyle of the tibia. However, as Dr. Kirkpatrick's treatment was less severe than trephining, it deserved attentive consideration and a fair trial. It was not empirical, although proved by experience. It was founded on sound physiological and pathological considerations, and it was one which, if it emanated from that Society, would tend to add to the laurels which the Society had gained by the noble improvements in surgery—especially in the treatment of joints—which had emanated from it.

Mr. B. W. RICHARDSON observed that, if he did not mistake, the same principle of treating the diseased bones of joints had been followed by Chassaignac for some years. It appeared to him (Mr. Richardson) that the object of Chassaignac and Dr. Kirkpatrick was the same, although produced in a different manner; the former being in the habit of using drainage tubing, &c.—Dr. Kirkpatrick, caustic. He (Mr. Richardson) recollected having a conversation some time since on the subject, with the Rev. Professor Haughton, during an excision of the knee-joint by Dr. Barton, in the Adelaide Hospital. Dr. Haughton told him (Mr. Richardson) that he had seen, in Paris, diseased joint-bones, through which Chassaignac had passed drainage tubing, and with excellent results.

In confirmation of Mr. Richardson's observation,

Mr. EDWARD HAMILTON stated that he had seen Chassaignac pass drainage tubes through diseased tarsal bones when he (Mr. Hamilton) was last in Paris.

#### IDIOPATHIC GLOSSITIS.

Mr. CROLY stated—At the meeting of the Surgical Society held on the 18th of January, I had the honour of reading a communication on acute glossitis, illustrated by seven cases, which occurred in my own practice. By a curious coincidence, I have had (since bringing the subject under the Society's notice) another case of idiopathic inflammation of the tongue under my care in the City of Dublin Hospital. The patient was seen by most of my colleagues, and also by several medical friends. I shall, as briefly as possible, detail the history of the case, which was one of unusual severity:

About eight o'clock on the night of the 23rd of January, I received a letter from Mr. David Hadden (one of the resident pupils in the hospital), requesting me to visit, as quickly as possible, a girl just admitted, who was suffering from urgent dyspnoea and symptoms of glossitis.

On arriving at the hospital I found a girl sitting up in bed, suffering from alarming dyspnoea. Her tongue filled the entire cavity of her mouth, and its convexity almost

touched the palate. Saliva poured copiously from her mouth: her head was thrown back; her countenance was anxious, and she breathed entirely through the nostrils; pulse 120 in the minute. She could not speak. I ascertained, on examination, that the region of the tonsils of each side was free from swelling, and not tender on pressure. The submaxillary region, however, was enlarged, and very sensitive to the touch. The girl could not bear any pressure on the apex of her tongue, which protruded between the teeth, and was covered with a white exudation. The breath was fetid. There was no tenderness of the gums, and the patient had not taken mercury or any other medicine lately.

The girl's mother states she was in good health until the 17th of January, when she caught cold by taking off her boots and walking in the snow. She complained of *shiverings, headache, thirst, and soreness of her tongue*. She was menstruating at the time, and the discharge was checked.

It was to me quite evident that she was suffering from acute glossitis of a very severe form, and from the aggravated symptoms I felt most anxious about her. I lost no time in introducing a sharp-pointed curved bistoury into the mouth, keeping its blade flat towards the tongue until its point reached the base of the organ, and then, having turned the edge of the knife towards the tongue, made a rapid, deep longitudinal incision between the raphe and edge, and parallel to the septum. I quickly changed the bistoury to the other side, and made a similar free incision. The hæmorrhage was copious.

The relief to the breathing was almost immediate. I directed three leeches to be applied to each submaxillary region, and a hot poultice put on when the leeches came off. The patient tried to swallow some milk, but could not succeed. She took ice in small pieces, and enjoyed it very much. A turpentine enema was administered, as the bowels had not acted since the commencement of the attack.

24th. Mr. Hadden's note says: Patient had a restless night; she swallowed a little wine-and-water with difficulty, and continued the ice; bowels were freely moved; countenance less distressed, and the breathing not so difficult.

Six P.M. On visiting the patient I found her symptoms not as much relieved as I had anticipated, and as the tongue was still very much inflamed, I made incisions again into the organ in the same situation as the previous ones. A large quantity of blood escaped, and as she could not swallow, I ordered nutritive injections of beef-tea and whisky to be administered every third hour.

Eleven P.M. Breathing much less difficult; the girl could speak a little; her voice, heard for the first time since admission, was peculiar, and the speech "thick" and indicative of the disease; pulse 112, and stronger.

25th. Patient slept tolerably well last night; she can swallow a little, and still enjoys the ice; nutritive injections continued.

26th. Pulse 100; saliva still flowing freely from the mouth.

27th. Tongue still much enlarged, and protrudes beyond the teeth; the patient cannot swallow enough of nourishment to keep up her strength. Ordered nutritive injections every hour.

28th. Pulse stronger; patient swallows a little iced milk; white exudation is separating from the tongue.

29th. The incisions, so far as they can be seen, are mere lines; the edges of the tongue are deeply indented from the teeth; the *hardness and enlargement consequent on the effusion of lymph still remains*.

Mr. Croly proceeded to say that, on the last occasion when this subject was under discussion, he mentioned that the first case described by him coincided with those published by Dr. Fleming, where the disease commenced under the chin. In the next case half the tongue only was affected; the third case involved the whole tongue; the fourth case only half the tongue; the fifth case the entire organ; and the last case arose from erysipelas. He (Mr. Croly) considered that the case which he brought before the Society that evening was a typical case of glossitis; and he was

certain that if the tongue had not been cut freely and deeply, the trachea should have been opened to save the girl's life. Whatever the case might be termed, it required leeching and a free incision. The tongue swelled so much, that the upper teeth were embedded in it, leaving holes one quarter of an inch deep which any of the members could see if they pleased, as the girl was in attendance for that purpose.

Merrion-street.

DEAR CROLY,—I read your cases with interest, and have no doubt that the term "glossitis" applied to them is quite correct. They (the cases) are obviously identical in character with those to which you allude as described by myself some years since. Why the term "glossitis" is objected to is not, I think, very clear; and it appears to me that dissentients are inclined to state the distinctive characters which THEY assign to genuine glossitis, as contrasted with the phenomena of the cases related by you and myself. In our cases we have an affection arising suddenly, running a rapid course, attended by pain, swelling, tenderness, and increased vascularity of the organ engaged, and frequently followed by abscess—the latter not uncommonly in the substance of the tongue. The disease finally is arrested by the same measures which are efficient in inflammation. I do not, therefore, feel myself authorized to resort to hair-splitting, and to refuse to place the disease in the category of inflammation, merely because authors assert that acute glossitis is rare. I well recollect a similar case, many years since, in the hands of Sir P. Crampton, who did not hesitate to call it *glossitis*, and to treat it as such.—Yours, sincerely,

T. J. GEOGHEGAN.

Dr. H. J. Croly.

Dr. FLEMING stated that he adhered to the original observations which he made in his paper, but which he had not read for a long time. That paper was based on cases which had fallen under his immediate observation, and, with respect to those cases, he commenced by saying that there were two forms of glossitis—one idiopathic, the other symptomatic. He mentioned the treatment applicable to idiopathic cases, which, he repeated, were cases of extremely rare occurrence. With respect to the cases of symptomatic glossitis, such as traumatic, or arising from other causes, he had mentioned the treatment suitable for them likewise, and their characteristic symptoms. If he made any remarks on the last evening as to accuracy in diagnosing the disease, they were as much applicable to himself as to others, for even the best of us might be mistaken. As to affections of the tongue that were confounded with glossitis: there were affections of that organ which suddenly supervened, but that wanted some of the true symptoms. Sometimes the tongue swelled suddenly, and the swelling would as suddenly subside, unaccompanied by fever, and supervening as suddenly as they found these sudden congestions occurring in other situations. If they analysed the case brought before them that evening, he had a little doubt in his mind whether it was a case of "idiopathic" glossitis. It was stated there was a sudden suppression of the catamenia. That might have produced this sudden congestion of the tongue, and might have produced all the symptoms. He should be disposed to call it a case of symptomatic, rather than idiopathic glossitis. His object was to elicit information, and he acknowledged that he always derived more or less benefit from the discussions which took place at that Society.

Mr. PORTER thought that Dr. Croly was justified in coming forward and explaining the case, as he had now done, so plainly. He (Mr. Porter) had not the slightest doubt, from his description of the case before the Society, that it was one of glossitis. It was not a common disease. He never saw but one case of idiopathic glossitis, and that was under the care of the late Dr. Graves. He had seen some severe cases of swelling of the tongue. One of the most severe he had ever seen was shown him by the late Dr. Lagrange, and it arose from the sting of a wasp.

Dr. WHARTON said he visited the hospital at Dr. Croly's request, to see the case, and no doubt whatever the tongue presented all the signs and symptoms of abatement of an acute attack of inflammation. The impression of the teeth was left very deeply indented in the tongue, showing how

great the swelling and consequent pressure must have been. He admitted the disease was a very rare one, but had no doubt this was a case of glossitis.

Dr. BENSON saw the case also, and concurred in the opinion that it was one of acute glossitis. As to attributing it to the suppression of the menses that was out of the question. No one ever heard of a swelling so enormous, and accompanied with fever and pain, arising from such a cause.

Mr. FLEMING observed that he feared he had been misunderstood. He did not deny that the case was glossitis, his impression, however, being that it was symptomatic, and not idiopathic inflammation of the tongue.

Dr. O'GRADY said that he had seen the case, and had no doubt it was a most urgent case of acute glossitis.

Mr. CROLY—This case was admitted to hospital without any previous history. He took it as he found it—a case of enormous swelling of the tongue, filling the mouth so closely that he had to pass in the bistoury flat in order to make the incision. The girl had no wound of the tongue; therefore, it could not be traumatic; it was not likely to have arisen from the sting of a bee at this season, and as to suppression of the menses he thought that was only a coincidence. He mentioned the circumstance because it was told to him, not because he thought it had any influence in causing the disease. The mother's history of the case was that the girl caught cold, shivered, and felt unwell. The class of people to which she belonged often attributed affections to suppression of the menses, and she mentioned that circumstance, but he did not attach any importance to it. The tongue did not swell rapidly; the case began with pain in the tongue, then difficulty in swallowing, and so went on until she came into hospital with the organ enormously swollen, as he had described. He was perfectly satisfied that the girl would have lost her life if an incision had not been made.

Mr. B. W. RICHARDSON read the following paper by Dr. Johnson of Kilkenny:—

CASE OF PROTRUSION OF INTESTINES THROUGH AN ABDOMINAL WOUND, ENDING IN RECOVERY.

By ZACHARIAH JOHNSON, A.M., F.R.C.S.I.

Wounds and injuries of the great cavities must always present unusual interest to the surgeon, on account of the great importance of the organs contained within them, and unavoidably implicated or endangered. The following case of protrusion of the intestines through an abdominal wound, and ultimate recovery, will not, I hope, prove uninteresting or uninteresting:—

On the 8th of September, 1865, a farmer, named Thomas Maher, when on his way home from market was wounded in the abdomen with a knife or dagger by one of his companions. He almost immediately felt the bowels protrude. He was carried at once to a police barrack, which was scarcely more than a quarter of a mile distant. I saw him between eight and nine P.M., about an hour and a half after the injury. He was greatly alarmed, but not suffering as much as might be expected from prostration or pain. On opening and removing his trousers nearly all the floating and movable intestines were exposed to view. The first impression was that the wound, through which they had escaped, must be a very large one. The intestines were intensely vascular, of a vermilion hue, partly from exposure to the air, and partly from rubbing to the rough material of a coarse trousering; they were also much distended with gas. From the appearance of the viscera, it was hard to think that inflammation of a formidable character would not ensue, although the distended condition of the protruded bowels favoured the conclusion that they had escaped perforation. He had lost a considerable quantity of blood, but at this time there was little or no bleeding.

I proceeded at once to replace the intestines, but found the wound not at all so large as I had expected, judging at first from the great mass of intestine which was exposed to view. I found very great difficulty in restoring the bowels to their natural position, and it was only by manipulating patiently for a very long time that I succeeded, inch by

inch and bit by bit, in getting them back into the abdomen. A piece of omentum, which could not be got to return into the cavity, had to be excised. The wound was found not to be at all as large as at first supposed. It was rather less than two inches in length—rather oblique, and to the left of, and a little below, the umbilicus.

The edges of the wound were now brought into apposition, and firmly secured by several strong interrupted sutures, an ample compress placed in front of them, and secured in its position by large adhesive straps, and a broad roller firmly applied over all.

The sutures were effectual in preventing any further protrusion of the bowels, although it was difficult to prevent it until their insertion.

He was now placed in the police sergeant's bed, and given a full opiate, with directions to observe strict quiet, and abstain from all food and drink. The abdominal muscles were relaxed by raising the head and shoulders, and placing a cushion under the knees, and this position he was ordered to observe until seen again.

I saw him early on the following morning in the police barrack. He had passed a good night, had some sleep, and was free from pain. His condition was altogether so favourable, that I advised his removal into the county infirmary, a distance of about two miles from the barrack.

He was carried carefully on a stretcher, and not allowed to make any effort or exertion whatever. He did not suffer in any way by the move; the full influence of the opium being kept up all through. Free doses of opium were now given at such intervals as the circumstance called for. Pills with grs. ij of the pulvis opii were at first given on every threatening of pain, which were gradually reduced in quantity as the danger of inflammation decreased. He was allowed the smallest possible quantity of food and drink.

It would be unnecessary to enter into a minute detail of symptoms and treatment from day to day. The case progressed favourably, and at no time did the dreaded peritonitis set in. The same principles of treatment were observed throughout, only modified in degree, as the danger became more remote. The doses of opium were gradually lessened until their use was left to the promptness of discretion or pain. Milk and light farinaceous food was allowed in quantity progressively increased.

No attempt was made to interfere with the action of the bowels, which remained torpid for several days, but then acted spontaneously and naturally, affording additional evidence of the satisfactory progress of the case, and absence of those lesions and complications which there was such great reason to apprehend at first.

The sutures were not disturbed for several days, and then only one by one, as each appeared to irritate or cut its way through the involved parts. Strong and ample straps of adhesive plasters, supported by compresses, and a broad abdominal bandage, formed the only guard against escape of the intestine on the removal of the last suture. At no time, however, after the insertion of the sutures did any portion of the abdominal contents escape, and the wound closed in gradually, healing from the bottom until the process of cicatrization was complete.

This man left hospital about a month after the injury in perfect health, wearing an umbilical truss over the site of the wound, as a measure of precaution. I saw him several months afterwards; he was then in perfect health, and continued to wear the truss, but only as a precaution, as he was unconscious of any inconvenience or evil consequence from the wound in the abdominal walls.

I have ventured to offer these particulars of this case, although aware there are several on record equally striking and remarkable, where recovery followed on extensive protrusions of the abdominal viscera through wounds more or less extensive in the abdominal parietes. The addition of one such to those already recorded, with a detail of the treatment which conduced to a result, successful beyond all reasonable anticipation, may not be wholly useless, as tending to confirm the line of practice suitable in such cases, and will, at least, be reassuring to the young surgeon, should he ever meet with such a formidable accident.

I would here add, that at first small doses of calomel were combined with the opiate pills. This was done in the expectation that peritoneal or enteritic inflammation would almost surely follow on the violence which had been sustained by parts of such delicate organisation, and with the view of being able to bring the patient readily under the influence of the mercury, should it become necessary to do so. However, so favourable was the progress of the case, that the mercury was very soon omitted, and the event entrusted to the salutary influence of the opium alone.

At no time was it necessary to resort to either general bleeding or leeching, but it should be remembered that he lost a good deal of blood before he received any medical assistance.

The difficulty of getting back the intestines was so great, that for some time I almost despaired of being able to do so without dilating the wound—a measure to be avoided, if possible, for many obvious reasons; however, they were eventually restored to their natural position by the exercise of much patience and perseverance. But the intensely vascular condition of the intestines from exposure to the air, and friction with the coarse clothing of the patient, together with the amount of tedious manipulation to which they were subjected, made it a matter of surprise that formidable inflammation did not follow, and still more so that recovery should have been attained without any of the dangerous consequences which, at first sight, seemed almost inevitable.

The PRESIDENT thought the society ought to be much obliged to Dr. Johnson for sending them the history of that important case. None knew better than those around him how frequently Surgeons met with these serious accidents, and also the difficulty in restoring the parts, protecting them, and saving the patients' lives. This case was admirably detailed, and the result was most fortunate.

Mr. PORTER said that one important feature in the case was the amount of handling and inquiry to the intestines without any serious consequences. They knew, in the present day, when ovariectomy was performed so frequently, the Surgeon endeavoured to deal with the intestines as delicately as possible. Here was a case where they were exposed to friction and to exposure to the air, and yet the patient had recovered.

Mr. B. W. RICHARDSON remarked that it was wonderful what the intestines would sometimes bear with impunity. It was only that morning he had been speaking to Professor Sinclair on the subject and who mentioned a case quite confirmatory of those alluded to by Dr. Johnson. It occurred in the practice of Dr. Shekleton, a former master of the Lying-in-Hospital. A French prisoner was brought to Dr. Shekleton after one of the battles in the Peninsula, where Dr. S. was then serving. The man had a large, dark, nearly black, pedunculated protrusion through the anterior abdominal wall. On examination, the tumour was found to be covered with dirty adherent charpie, which, on being carefully removed, disclosed a large mass of intestine of a nearly black colour. Further investigation led to the discovery of a ligature which tightly constricted the neck of the protrusion, and which had been placed there by some person, whether professional or otherwise he was unable to say. Dr. Shekleton cut and removed the ligature, and a careful examination having led him to think that the intestine was not dead, and had a chance of recovery, he returned it into the abdomen, and secured the apposition of the edges of the wound of the abdominal wall. The man subsequently made an excellent recovery, and was exchanged.

The PRESIDENT said this case tended to the same conclusion they had arrived at that night as to conservative surgery. Even in the worst cases of strangulated hernia, the surgeon was often astonished after returning the dark, almost black, intestines to find the patient recover, while often he would operate in a case not apparently so bad, and in which he had reason to anticipate a favourable result, and yet the patient died. He thought they should be much obliged to Dr. Johnson for his valuable paper, and

that they ought to encourage country practitioners who frequently meet with very interesting cases to communicate them to the society.

#### FURTHER NOTES ON ANATOMICAL IRREGULARITIES.

By ALEXANDER MACALISTER.

It will be remembered that a few evenings since I exhibited to the Society a specimen of irregularity in the branches arising from the arch of the aorta, in which the two carotids arose by a common trunk, and the right subclavian, arising from the left extremity of the transverse portion of the arch, ran behind the trachea and oesophagus over to the right side. It is a curious coincidence that during the last week I have met with a second example of this same arrangement, differing from the former only in one respect—namely, that the arch exhibited no lateral inclination, but lay entirely to the left of the spine, its transverse portion passing directly backwards. The right recurrent laryngeal nerve, in this instance, did not wind round the subclavian—a fact which was commented on in connexion with the last described example.

I have met with another interesting arterial irregularity which might be of considerable surgical importance—namely, the origin of the internal or circumflex femoris vessel from the internal or deep epigastric, about half an inch above the origin of that vessel, from the external iliac. Burns has described an instance in which this vessel arose from the external iliac, and I have seen it coming off from the femoral (a very common arrangement), and when it comes from the profunda it is very frequently above the external circumflex. I have seen it likewise arising by a common trunk with the external circumflex, as Green has reported, but I have never before seen or read of instances of the variety.

I have likewise to exhibit a specimen of the extensor medii digiti, nearly separate from the indicator at its origin, but completely distinct for more than two-thirds of its course. This muscle has been occasionally noticed before, and Mr. Wood published an instance of the kind in the Proceedings of the Royal Society, June, 1864.

Another interesting variety consists in the presence of an extensor of the first phalanx of the hallus, separate from the long extensor of the great toe. This muscle is one of common occurrence, generally is only attached to the annular ligament, or to the lower sixth of the tibia; sometimes it extends higher up. I have seen it merely a slip springing from the extensor hallucis longus proprius, or as a tendon with no muscular fibres attached. I have seen, but much more rarely, an extensor ossis metatarsi hallucis, and once found the three slips to coexist as in the thumb.

In the third specimen on the table, the palmaris longus will be seen to present a moderately thick fleshy belly for seven inches of its central portion, with an inch and a half of tendon at its origin and at its insertion.

## Correspondence.

### QUACKERY TRIUMPHANT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With your permission, I would again wish to say a few words on the subject of the above social evil, and this for two reasons, in the first place with the intention of bringing the subject under the notice of the profession through the instrumentality of your columns, and thus indirectly of the community at large, in the hope that it may at no very distant day engage the attention of Parliament; and secondly, as I consider quackery to have arrived at a new and greatly advanced phase since I last had the honour of advertizing to the subject in the pages of the MEDICAL PRESS AND CIRCULAR.

I shall first treat of the second proposition, viz.:—That quackery has made giant strides within the past six months, as evidenced not only by the numbers, but audacity of the individuals concerned therein.

If the proverb be true, "that the darkest hour comes immediately before the dawn," verily we must be on the eve of a most luminous period in medical science! for I am of opinion, that the gloomiest days of medicine could not boast of any, thing like the numbers of vile pretenders to medical knowledge which swarm around on every side at the present time—even in the enlightened metropolis of Ireland; in proof of which let any one glance at the pages of the *Irish Times* during the past few weeks, in which I have counted during one week no less than forty advertisements emanating from obscure confidential quacks, native and imported—a marked feature in most of which is, that these sapient and philanthropic individuals state that they have discovered how to treat successfully all diseases of the nervous system *without medicine*, in a few days—albeit they insert their ability and willingness so to do in the department styled "Medical." By this "wonderful medical discovery" the modern quack (of the past six months) has shown himself, a vast improvement on the antiquated animal who formerly was at least obliged to cure the disease by levelling a pill at the part affected; but, forsooth, all these medical cures must now succumb to the enlightened discoveries of philanthropic individuals, who, for the mere consideration of two penny stamps can thus dispense immediate health and happiness to all willing to accept it! Witness the following—extracted from the *Irish Times*:—

"Just Published, post free for two stamps.—Wonderful Medical Discovery, demonstrating the true cause of nervous, mental, and physical debility, lowness of spirits, indigestion, want of energy, premature decline, with plain directions for perfect restoration to health and vigour—Without Medicine.—Sent free on receipt of two stamps, by W. Hill, Esq., M.A."

So much for specimen number one. Now for number two, which, if not emanating from the same worthy and enlightened discoverer, I think he should put his "M.A." knowledge to work, and make a further discovery of the piratical individual who seems to have appropriated his style at least. But perhaps I may wrong him, for "facies non omnibus una, nec diversa tamen, qualis debet eni sororum." (Extracted from the *Irish Times*):—

"Post free for two stamps.—The Masterpiece of Medical Science.—The new discovery for the self-treatment and cure of physical debility, pains in the back and limbs, nervousness, impaired sight and memory, and premature decay, without medicine.—Sent free on receipt of two stamps, by G. Clinton, Esq."

In the following, the sapient author seems not to have arrived at so high a standard, though discovering much, as to be able to cure all diseases *essc medicina*. (Extracted from the *Irish Times*):—

"Just published, post free for two stamps.—Grand discovery in medicine.—Read the Secret Friend, a new medical guide for the cure of nervousness, indigestion, physical debility, lassitude, and all other cases requiring confidential advice, arising from injurious habits, &c. This valuable work will be sent free from the author's residence, secure from observation, on receipt of two stamps. Address Dr. J. A. Barnes, —."

Calculated as the above undoubtedly are to entrap the unwary and thoughtless, I consider the following to be of a much more pernicious tendency, appearing, as it does, in the *Irish Times* of January 12th, et sequentia, *immediately before* the "leading article," thus *seeming* (I can hardly conceive that it *really does*) to appear under editorial sanction:—

"Nervous Diseases of Women and Children—namely, hysteria, spasms, fits, convulsions, and other forms of nervous affections, great and permanent benefit, even in the most hopeless cases, and a cure where this is possible may be confidently expected. Please to send a full, correct, and plain statement of the case as to the age of the invalid, the cause, symptoms, duration, &c., of the illness and the nature and effects of previous medical treatment for a reply to B. 485, Medical, office of *Irish Times* newspaper, Dublin."

Bearing in mind that the above specimens are only a few out of the forty quack advertisements appearing during the space of one week, in one of the Dublin newspapers, I think most persons will concur in the truth of my statement as to the great increase of this opprobrium to legitimate medicine; and consequently the very great bodily, social, and material injury to which both sexes are exposed to from this disreputable class of human vultures. But were confirmation necessary to prove the extent and wide-spread nature of this evil, I think the following amply sufficient, as it

not only shows the ready method by which the ensnaring advertisements of designing quacks can be imported into the bosom of the most respectable families, but also another form under which this protean monster seeks to draw victims to its shrine—I think it worthy of insertion—About the commencement of the present year I observed individuals hawking, about the principal thoroughfares of Dublin, almanacks for the year 1867. Now, as this is a class of publications no one could conveniently do without, and the outlay to procure a “respectable looking one” though marked “three pence” was only “one penny.” I observed numbers possess themselves of “The Dublin Household Almanack,” and as it appeared “value for the money,” I also bought one. On examination I found it to contain twenty-four pages, small 8vo, and of that number, the “Almanack” properly so called, occupied only twelve pages, exactly one-half, the remaining half being actually “crammed” with quack advertisements of every description, the less objectionable consisting of—Blair’s gout and rheumatic pills; Frampton’s pill of health; Hayman’s balsam of horehound; Dr. A. Coffin’s trichopherous; Morrison’s pills, to cure cholera; Norton’s ditto; Keating’s cough lozenges; Holloway’s pills, &c., &c., “et hoc omne genus.” And as a specimen of the obscene class, the following will serve:—

“Wray’s Balsamic Pills, (established 34 years), a certain cure for urinary diseases, whites, gravel, affection of the kidneys, pains in the loins, lumbago, stone in the bladder, irritation of the bladder or urethra, disease of the prostrate glands, and a decided specific for gout and rheumatism.—Price 2s. 9d. and 4s. 6d. per box.—Sold by Thomas Hackett, 18, Lower Ormond-quay, Dublin.”

And—

“Medical advice free.—Dr. Lea may be consulted gratuitously in the following disorders, which he has many years most successfully treated, viz.—consumption, dropsy, hooping cough, gout, rheumatism, sciatica, paralysis, female and nervous affections, diabetes, cancer, scrofula or king’s evil, scurvy, and eruptions generally, likewise other complaints, including those of a confidential nature, (in both sexes), on receipt of stamped envelope for reply.—Address, G. Lea, M.D.”

Not to enumerate many others—now, sir, here was a book, which even the most fastidious could not from its name and external appearance object to, published by a Dublin publisher at a very low figure, sold in numbers in the public thoroughfares of Dublin in open day and all the day, and who can sum-up the amount of suffering and discord it is calculated to introduce into families; for believe me the poet Juvenal has struck the right string when he says—

“Fallit enim vitium specie virtutis et umbra,  
Quum sit triste habitu, vultuque et veste severum.”

However, not to trespass further on your space, I think I have abundantly proved my position; and will therefore proceed to fulfil my first intention in writing this letter, viz., to endeavour with your co-operation to bring the subject prominently before the attention of the profession, and through them of the community, and especially members of the national legislative body. That Parliamentary intervention is necessary, I think is fully proved by the simple fact alone, that although the “Medical Council” has numbered years by its existence, yet it has done literary nothing, or worse than nothing, to remedy this evil, nor, practically at least, has it to the slightest extent enabled the general public to distinguish the really qualified from the mere impudent vile advertising pretender. But apart from Parliamentary interference, can we not do something ourselves, at least to ameliorate this evil, if not eradicate it? I think a united Profession such as ours ought to be able so to do, if backed and assisted by our Colleges and Corporate Medical Societies; and I would suggest that a meeting of the Profession should be convened to take the whole subject into consideration with a view to ultimate proceedings, legislative or otherwise, to have this vile class of impostors suppressed, and thus remove for ever an evil that has too long been an opprobrium to our noble Profession, and a disgrace to our country.

Hoping, sir, as you have ever been foremost in advocating the claim of anything calculated for the advantage of the profession, or the mitigation of the wrongs of suffering humanity, that you will not permit this subject to be overlooked, but will give it the benefit of your able co-operation until something definite has been effected, and apologizing for occupying so much of your space—faithfully yours,

JOHN S. A. CUNNINGHAM, M.D., &c., &c.

## MEDICAL ACT'S AMENDMENT BILL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your paper of February 20th, Dr. Williams asks, “What is to be done with students, medical assistants, and midwives, if the proposed bill proves efficacious for the thorough and legal protection of the medical profession?”

As to midwives, the sooner their practice is stopped the better. They attend principally upon the very poor, and by so doing they deprive the Union Medical Officer of the fee allowed by the Poor-law Board. If we add to the above cogent reason the fact of the general ignorance of the greater class of women practising midwifery, I think it is high time some steps should be taken to protect the lives of those who are foolish enough to employ them.

With regard to medical assistants, why should they not be compelled to register? By so doing medical men could ascertain the character of an applicant for an assistant, by referring to a Medical Assistant’s Directory, which might be published under the authority of those appointed as Registrars. All persons claiming to be registered as assistants to produce to the Registrar evidence as to their ability to act in that capacity, and certificates as to their general character. No one to be allowed to act as an assistant unless registered, and all registered persons to have the title of assistant-surgeons as long as they act in that capacity. A fine might be inflicted upon all unregistered persons using the above title, and upon those acting as assistants, unless duly registered. I do not think that assistants would object to the above, and by this means the difficulty with regard to them would be overcome, and they themselves become not only an important but a recognized branch of the medical profession. Students are already compelled to register.—I am, sir, respectfully yours,

T. T. B.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last issue of THE MEDICAL PRESS AND CIRCULAR, I see a letter from Dr. Williams, regarding the Medical Act, and the proposed Amendments. In his views I fully coincide, and I have no doubt the entire profession will do the same. It is well known that quackery is as rampant as ever, by adapting itself to the requirements of the “Medical Act,” and no longer assuming those titles and qualifications by which legitimate practitioners are known. In this town we have one of the voracious tribe, doing a large business. For the last few years he has ceased taking medical titles, and thus, while avoiding the penalties imposed by the “Act,” he continues quacking away as formerly.

Let a clause be inserted in the proposed “Amendment Bill,” forbidding any person to act as a medical man, except he be a qualified and registered practitioner. An exception can be made in the case of medical assistants, etc.

I think the Medical Council, as a representative body (?) should insist on the Legislature the great necessity of something similar to what I propose, for the purpose of guarding the just rights and interests of the profession. No doubt, union and concord among local practitioners would go far to suppress the traffic of any particular quack; but as doctors differ, not only professionally, but socially and politically, this happy state may not be attainable at all times and in all places, consequently, a legal enactment is imperatively required.—Yours, very truly,

CHARLES GARLAND, L.K.Q.C.P.I., L.R.C.S.I.

## TREATMENT OF ENTERITIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On looking over my case-book for 1823, I found the following which may, perhaps, prove interesting to some of your readers.

In August, 1823, we were at Carthage, on the Spanish Main, and we had hardly anchored when a boat came alongside with a request that the doctor should go on shore, and visit professionally a respectable French emigrant merchant, who was reported to be in a dying state from the disease called “typhus fever.” I went on shore and found a rather corpulent elderly gentleman in bed, in a fine large airy room. On examination I found all the symptoms of the disease called “typhus fever,” but I found also that he had “acute enteritis;” he could not bear the slightest abdominal pressure. His French physician had given up all hopes of him, his treatment had been quinine and ammonia; the family were very anxious that I should do something. Foreigners have an idea that English

naval surgeons are very skilful, at all events their advice is always solicited in case of necessity.

I did not admire this case very much; however, I ordered thirty grains of calomel, and five of opium, instantly, the calomel to be repeated every hour, in conserve of roses. I ordered also one ounce of the camphorata mercurial ointment to be rubbed well into the thighs and arms every hour. I stimulated gently the thighs and arms by a smooth iron heated in boiling water, so as to create rapid absorption. In twelve hours the symptoms were alleviated: in twenty-two hours complete ptyalism had taken place, when I pronounced the patient out of danger, so far as the disease was concerned. In the meantime I had ordered an enema consisting of two ounces of castor-oil beat up with the yolk of two eggs in a pint of warm gruel, which procured two very copious and highly fetid evacuations with great relief. Having given the necessary directions for future treatment we left next day, and of course I heard no more of it.

Four years afterwards I visited Carthage, and we had not been about two hours at anchor when I received a friendly visit from my friend the merchant, who told me that he had had a rapid recovery, and that next to God, for he was a good Catholic, he was indebted to me for his life, and that my instructions had been most scrupulously observed. As I refused any pecuniary consideration, he sent me on board, just as we had weighed anchor, a box containing presents to the value of about 300 dollars.—I am, sir, your obedient servant,  
ALEXANDER LANE, M.D., Surgeon Royal Navy.

P.S.—About five years after this I received a letter from the French Physician which had followed me from station to station, thanking me for the valuable information he had received, that he had adopted my treatment, and had been most successful. My ideas about this disease had not been quite matured at this period.

### THE IDIOT QUESTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The idiot question is a very important one. In idiots the organs of relation are undeveloped as well as imperfect, and the mind remains dormant. There is, nevertheless, a great diversity in idiots, for some are very much more susceptible of culture than others. *In limine*, it is undesirable that numbers labouring under a common deficiency should be herded together. It would be better that each single idiot, every lunatic, all deaf and dumb persons, should be surrounded by those, only, who were of sound mind and perfect faculties. This, however, in the first instance, at least, would be inconvenient, and therefore it is asylums become inevitable. Nevertheless, as soon as possible, the developed idiot should be placed in ordinary schools, where his deficiencies should be supplemented by the intelligence of others. It may be objected that the idiot needs special training. In fact, he needs both special and general training, and the teachers in ordinary schools could very readily make themselves conversant with the special forms of culture needed by idiots and deaf and dumb persons. For it is, in truth, a very great loss to those who are maimed in faculty and intelligence to be shut out from others who, in these respects, are more happily circumstanced; and, their deficiencies notwithstanding, there are many things in which idiots and imbecile persons might, to a certain extent, share in the common culture of those around.

The maintenance of idiots, as of other unhappily defective individuals, should fall upon the community at large. It is not right or fair that a few charitable persons should be exclusively mulcted, every one should bear their proportion. In this way the burthen would fall heavily on none. The practice of raising a fund, and then laying it out in brick and mortar is a bad one. The building is raised, and there is nothing left to maintain it, save the onerous and precarious expedient of sending round the hat. I submit that in all such cases the sum, whatever it might amount to, should be put to interest, and that the interest alone, supplemented by any funds in aid that were obtainable, should be applied to the construction of proposed asylums and to their after maintenance. So impressed with the importance of this, not long since, was a merchant in Boston, U.S., that when he left 80,000 dollars for a benevolent object, he stipulated that not a single dollar of the money should be expended in brick and mortar. The consequence was that people clubbed together and built the asylum, which, subsequently, owing to the merchant's provident forecast, had an ample revenue for its maintenance.

Supposing the asylum for idiots once established, however, a

great enemy awaits it, and that is the spirit of mere routine. Routine, it is true, we must have, but unmixed routine is greatly to be deprecated. It shuts out improvement, and contracts our usefulness. I once visited an asylum of note for idiot children. The general appointments and management were worthy of every commendation, but the special culture of the inmates appeared to me to languish, in fact, seemed in many respects quite unworthy of the munificent provision. Idiot children, indeed, when they attain a certain forwardness, would be better circumstanced if mixed up with, and sharing the culture bestowed on other children. They would thus, as far as their low estate would permit, share the general culture of the multitude, and reap the advantages flowing from that great implement of human advancement, education to wit, which I firmly believe, is destined one day to regenerate the world.  
HENRY MACCORMAC, M.D.

## Parliamentary Intelligence.

### HOUSE OF COMMONS.

FEB. 25TH.

PETITIONS were presented, by M. AKROYD, for granting the franchise to graduates in medicine, arts, and divinity; by Mr. GREGORY, from Mr. Joseph Hopton, Leeds, in favour of the educational franchise; by Mr. TALBOT, from the Board of Guardians of Bridgend and Cowbridge Union, in favour of the rating of mines, woods, plantations, and real property; by Mr. BUTLER, from the District Board of Works of the parish of Whitechapel, and from the Vestry of the Hamlet of Mile-end Old-town, praying the House to pass a measure for the equalisation of poor-rates throughout the metropolitan parishes on the basis of annual value; by Mr. LEFROY, from the President and Council of the Irish Medical Association, praying for superannuation allowances to medical officers of poor-houses and dispensaries.

### ENSIGN CULLEN AND SURGEON MORRIS.

In reply to Mr. Gilpin, Mr. MOWBRAY stated that there had been two separate courts-martial held on Ensign Cullen and Surgeon Morris, one of the charges being applicable to Surgeon Morris only. As regarded Surgeon Morris the trial commenced on Dec. 11th, and had not concluded when the last mail left. It was not usual to lay the proceedings of courts-martial upon the table, and until the whole of the proceedings had been completed he could give no answer.

### CRIMINAL LUNATIC'S BILL.

Mr. WALPOLE, in moving the second reading of this Bill, said its object was very important. There was at present no power to discharge from confinement the class of persons to whom it applied, when reported to be quite recovered, unless they were set completely free. But this measure proposed that, instead of simply discharging them out of prison without any conditions, the Crown should be enabled to impose conditions, so that they might or might not be subject to supervision as might be necessary.

The bill was read a second time.

FEB. 26TH.

### FACTORY CHILDREN.

Mr. FAWCETT moved a resolution affirming the expediency of extending the educational clauses of the Factory Act to children who are employed in agriculture, which was seconded by Mr. AKROYD, who spoke of the good effect of the Act in manufacturing districts.

Mr. TREVELYAN supported the motion, and dwelt on the importance of a combined effort for the advancement of general education. He thought the country gentlemen had not sufficiently stirred themselves in the matter.

Mr. GOLDNEY and Mr. READ denied that the country gentlemen were indisposed to promote education in the agricultural districts, but said the difficulty was to get the children to school and keep them there.

Mr. WALPOLE, while pointing out that the subject would be riper for discussion when the Report on the Employment of Children in Agricultural Districts in Gangs was before the House—as it would be very shortly,—intimated

that he had already arrived at the opinion that it might be necessary to extend some provisions of the Factory Act to children employed in agriculture. It might be necessary to enlarge the powers of the Commissioners to enable them to inquire into the educational condition of children not employed in gangs; and as he was about to bring in two Bills for the extension of the Factory Acts on Friday, he, therefore, begged Mr. Fawcett not to press his motion.

After some observations from Mr. H. Bruce, Sir F. Crossley, Mr. Alderman Lusk, Mr. Whalley, and Colonel Stuart, Mr. Fawcett withdrew his motion.

FEB. 27TH.

Petitions were presented by Sir F. Crossley, from the Halifax Poor-law Guardians, in favour of abolishing the power of removal of poor persons from one locality to another; and another praying that all mines and woodlands may be made liable to pay poor rates; by Mr. W. E. Forster, from the Bradford Board of Guardians, in favour of rating mines, timber plantations, and other property to the relief of the poor; and by Alderman Salomons, from the Local Board of Health for the district of Woolwich, for equalising the rates for the relief of the poor over the whole metropolis.

#### DUBLIN UNIVERSITY PROFESSORSHIPS BILL.

Mr. LAWSON, in moving the second reading of this bill, explained that its object is to remove another of the religious disabilities which Roman Catholics have just reason to complain of, by throwing open to persons of all religious denominations the three professorships of anatomy and surgery, chemistry, and botany in Dublin University. As far back as 1853 a commission, of which the late Archbishop Whately was a member, recommended the removal of these restrictions, so that the present measure came before the House with some authority. The Solicitor-General for Ireland, speaking in another place, seemed to take exception to the course pursued in introducing the bill; but he ventured to think the learned gentleman would hardly endorse the same argument in his place in that House.

Mr. LEFROY said he was in a position to give not only his own assent but also the assent of the Board of Trinity College to the bill. The reason why a measure was not introduced on the part of the university authorities themselves was owing to some diversity of opinion between the University Board and the Medical Board with regard to other amendments.

The bill was then read a second time.

The Solicitor-General for Ireland and Mr. C. Fortescue supported the second reading of the bill.

## MEDICAL OBITUARY NOTICE.

### DR. HORACE GREEN.

THIS distinguished American Physician has passed away at the ripe age of 64. His name has long been "familiar as a household word" on both sides of the Atlantic. He visited this country in 1838, and soon afterwards distinguished himself as one of the most original investigators of diseases of the air passages. He first described "follicular disease" of the throat, and first proposed to treat laryngeal diseases by topical applications, by means of a sponge probang passed down to and beyond the vocal cords. His views encountered great opposition. It was positively denied that the probang could be thus passed, and for many years poor Horace Green maintained the controversy almost unaided. Nor was opposition always fair. Indeed, few men have encountered so much undeserved obloquy. The New York Academy, after an enquiry, about which the less said the better, issued a "report" on the subject, bearing marks of personal hostility to Green. Many of our own authorities adopted the view that Green had been mistaken, and a good deal of controversy ensued. This is scarcely worth reviving. We rejoice that the brave old man survived to see the laryngoscope come into daily use, and demonstrate to the eyes of the most sceptical some of the positions he had laid down. It is, perhaps, rare for such true workers

and genial men, when once they have raised opposition, to live to see their own views so signally proved; and, no doubt, the recent brilliant progress of laryngoscopy compensated the subject of this notice, at least we may hope to some extent it did, for some of the most unhappy hours of his younger days. He died at Sing Sing, on the River Hudson, on the 29th of November last.

### SCHOLARSHIPS AT MERTON COLLEGE, OXFORD.

On Saturday, May 4, there will be held an Election at this College to—

1. One Classical Postmastership, value £100 per annum, tenable for five years.
2. One Mathematical Postmastership, value £80 per annum, tenable for five years.
3. One Classical Postmastership, value £80 per annum, tenable for five years.
4. One Natural Science Scholarship, value £60 per annum, tenable for five years.

[Candidates for the above must be under 20 years of age.]  
[Candidates for the Natural Science Scholarship will be examined in the ordinary Classical Matriculation subjects—viz., a portion of a Greek and Latin author, Latin writing, grammar, arithmetic, and algebra; and to those who pass this examination, papers will be offered in physics, chemistry, and physiology.]

Also,

5. One Classical Postmastership, value £80 per annum, for five years. Open to candidates of any age.
6. One Exhibition, value £25, for three years. Also with no limit to age.

Candidates are requested to send to the Warden, on or before Monday, April 29, certificates of age and testimonials of conduct.

The Examination will begin on April 30, at 9.30 A.M.

### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Quarterly Examination for Licenses in Medicine, February, 1867.

(Second Day.)

#### PRACTICE OF MEDICINE.—DR. MOORE.

1. Symptoms and physical signs of effusion in the left pleural cavity?
2. Symptoms and physical signs of aneurism of the transverse portion of the aortic arch?
3. Pathology and symptoms of tubercular meningitis?
4. Enumerate the exciting causes of hæmoptysis?
5. Describe the condition of the urine in albumenuria, and the complications which may ensue during the course of the disease?

#### MIDWIFERY.—DR. JENNINGS.

1. State Hunter's view of the placental circulation; also any one of the other theories that have been advanced on this subject.
2. Under what circumstances may the "tampon" be used during pregnancy? In what cases would its use be improper?
3. Enumerate the symptoms of rupture of the uterus. State the various modes of delivery in such cases, and the circumstances that may render each eligible or necessary.
4. Describe a well-marked case of "Chlorosis;" give also the pathology and treatment of this disease.
5. Describe purulent ophthalmia in newly born children, its causes, treatment, and possible results.

#### MATERIA MEDICA AND MEDICAL JURISPRUDENCE.

##### DR. BELCHER.

1. What is the composition of antimonium Tartaratum; and what is the mode of its preparation?
2. In what cases would you prefer the use of antimonial, alkaline, and saline diaphoretics; and of stimulant diaphoretics, respectively?
3. Prescribe a draught containing tincture of hyosciamus, for want of sleep in a case of Typhus occurring in an adult? (The prescription to be written in words at full length, without symbols or abbreviations.)
4. Describe the symptoms of poisoning by strychnia; and explain the mode of administering tobacco as an antidote in such cases.
5. How would you proceed to detect feigned epilepsy in a case of supposed malingering?

## MEDICAL GLEANINGS.

*(From the British and Foreign Medico-Chirurgical Review.)*

## ON OVARIOTOMY.

M. KEBERLE, who has done so much towards the introduction of ovariotomy into France, observes that the prejudices against it in that country are gradually diminishing, and comments upon the difficulties there are in statistically comparing this with the other great operations. These have so many analogies as to render them comparable, while ovariotomy is not only a more or less serious operation according to the general conditions under which it is undertaken, but also with respect to the particular cases and the different operative procedures. The surgeon who only operates in desperate and complex cases will necessarily obtain less successful general results than if he operated only in simple and favourable cases. The cases which are met with on the continent are generally unfavourable ones, the prejudices against the operation causing great delay in resorting to it. And yet, practised in opportune time, and before the development of grave complications, due to the prolonged existence of the tumour to theappings, &c., it has been subjected to, and to the adhesions which have formed, ovariotomy is relatively an operation of slight gravity, as is shown by the statistics which have been published of late years.

M. Kœberlé points out that the fatality of ovariotomy so frequently observed on the continent cannot be explained by the vitiated air of large towns, the nationality of the patients and the like, as other cases operated on in the same localities and occurring in persons of the same country, have succeeded well. At Strasburg, prior to his own successful operations, all cases proved fatal. His first fourteen operations, between 1862 and 1865, were performed at St. Barbe, an establishment which is far from presenting favourable sanitary conditions; and yet he met with ten recoveries to four deaths. Among these fourteen cases there were seven cases of single ovariotomy, one of which, occurring in a patient in very bad health, proved fatal. Of the seven cases of double ovariotomy three proved fatal, in two of these death being due to the operation itself. The number of cases of double ovariotomy which have occurred in M. Kœberlé's practice is very remarkable—viz., ten examples (four dying and six recovering) out of twenty-seven cases. Mr. Wells only met with seven double ovariectomies in 150 cases, and declined operating in seven other cases; and Dr. Keith has only had three double ovariectomies in thirty-five operations. To the present time M. Kœberlé has never, even in the most difficult cases, &c., in spite of most extensive adhesions, had to leave an operation unfinished. In his first fourteen operations there were two series of four successful cases separated by five cases giving rise to three deaths, and the practice of the English surgeons present very remarkable instances of series of successful and unsuccessful cases. The only case in which M. Kœberlé cut short the ligature of the pedicle, proved fatal, although the patient presented conditions very favourable to recovery. She died with symptoms of septicæmia forty-four hours after the operation, the only abnormal appearance found at the autopsy being a circumscribed sero-purulent collection around the ligature.—*Gazette des Hopitaux.*

## ON SOME CAUSES OF THE INCREASED SPREAD OF SYPHILIS.

PROFESSOR SIGMUND in this paper states some of the causes explanatory of what he says is a well-established fact, that syphilis is much on the increase. But it seems to us that the causes which he adduces have always existed, and in no wise explain any increase which may have recently been observed. First among these is the ignorance of the patient as to the nature and duration of his complaint, and the insufficiency of the time he remains under medical inspection—so that he is often unaware that he is ill, or believes himself cured long before he is so. The spot where the contagion operates may in the first instance exhibit very slight and fugacious changes of structure which by some simple application, and without medical aid, may disappear, to be succeeded within some weeks by more decided textural changes, such as induration, papulæ, &c., affecting the same part. In women, the diseased conditions are even much less readily detected than in men. During the period of incubation also, which is seldom shorter than two or three weeks, and in not a few cases extends to six, it is impossible for the patient to be aware of an affection which he

may have ample opportunity of spreading. How common, sexual intercourse is even after disease has made considerable progress, the experience of every hospital surgeon testifies. Next comes the generally spread opinion that the patient is cured as soon as skinning over of a sore has taken place. The specialist is in no such haste to pronounce on the matter until he has watched the patient during the period in which constitutional symptoms may arise. Many patients are thrown into a state of false security by the immediate employment of prophylactic measures, which experienced observers know to be useless or mischievous—the course of syphilis not being preventable by any such means. It will be long, however, before surgeons and their patients accept this opinion. Erroneous diagnosis causes the most different non-syphilitic appearances to be mistaken for the true disease until the characteristic symptoms of the latter appear. Lastly comes the difficult question of latent syphilis, during which persons apparently well continue long to have the power of affecting others. The general conclusion is that more careful examination and prognosis are requisite, and that the public should be indoctrinated in the necessity of these. Professor Sigmund protests against the inactivity of the medical profession in the face of the ever-increasing spread of the venereal disease; and maintains that even individual action may do much by propagating correct ideas upon the subject.—*Wien Med. Wochenschrift.*

## HOSPITAL GANGRENE.

DR. FISCHER has published an elaborate and valuable report on the cases of hospital gangrene observed in the External Division of the Berlin Charité during 1864-65. They amounted to 44 in number; 33 occurring in men and 11 in women. Many of the cases are given in full details, and the following are some of the conclusions which the reporter arrives at from their observation:—

1. Hospital gangrene may occur at any time of the year and in all states of the weather.
2. Although it may attack the strong and the weak, the young and the old, yet aged and cachectic individuals are its especial victims.
3. The hospital genesis of hospital gangrene is not tenable.
4. Hospital gangrene develops a specific contagion. (a) This contagion is transmissible by contact to wounds and animals. (b) It is not improbable that communicated to the air, it may infect wounds through this. (c) It is very questionable whether this contagion gives rise to a specific general infection before or after the development of the local malady. (d) Ulcers may be produced by hospital gangrene alike in all the tissues. (e) Ulcers and wounds of every description may be attacked by it. (f) For its development an ulcerated or exposed surface is not essential, as it may appear spontaneously in healthy skin. (g) A first appearance of hospital gangrene does not weaken its disposition to occur, and frequent relapses are not rare. In relation to treatment, Dr. Fischer speaks highly of the advantage derived from treating these patients in the tents placed in the grounds of the Charité. He insists strongly on the importance in the general treatment of pure air and perfect quiet, to absence of depressing emotions, and the necessity of good nourishment.—*Annalen des Charité Krankenhauses.*

## IMPROVED FORM OF PROBES FOR THE LACHRYMAL PASSAGES.

DR. WILLIAMS observes that "it has been customary to bend Bowman's probes to such a curve, as adapt them to the presumed direction of the nasal duct in each individual: but I have seen false passages formed where undue violence had been employed in their use; and, at best, the mucous lining of the sac or canal was often torn or abraded by the unyielding extremity of the probe causing considerable hæmorrhage, and giving rise to irritation which retarded the cure.

"I have found great advantage in using probes made with bulbous extremities of the six sizes of Bowman's scale, but very slender for some distance from their ends; so that the whole of that part of the instrument, without being unduly flexible, has an elastic pliability, enabling it to adapt itself to any sinuosities of the passage, and to find a route through the obstructions without laceration or contusion of the parts."—*Boston Med. and Surg. Journal.*

**LONDON AND GENERAL WATER PURIFYING COMPANY (LIMITED).**—The third ordinary meeting of this company took place lately at the offices in the Strand, Viscount Ingestre in the chair. The report of the directors, which was read by Mr. Ruding, the secretary, stated that the board had much pleasure in finding that the hopes they expressed in the last report of the expected increased returns had been more than borne out, the returns of the past year being three times those of the preceding one, and their only regret was that the heavy expenses incidental to an undertaking of this kind had absorbed the otherwise handsome profit. They trusted, however, by the experience gained, to be able to effect a curtailment of expenses without in any way diminishing the operations of the company. During the past year the company's cistern filter had been adopted at the Regent's-park and Tower Barracks, and had been selected by the London, Middlesex, and St. George's Hospitals, thereby demonstrating not only its superiority over all others, but the great importance, in a sanitary point of view, that was attached to the filtration of water by the highest medical authorities. Strong hopes were entertained that before long the authorities in India

would have satisfied themselves from the adoption of the cistern filter. The medical profession still continued proportionately the largest supporters of the company, and it was to them that the results hitherto attained were mainly to be attributed. The directors had again declined availing themselves of the power under the articles of association to accept fees, not wishing to divert the funds of the company for any purpose, but to devote them solely to the development of business to its utmost extent. The report was received and adopted.

**CONVICTION UNDER THE MEDICAL ACT.**—On Monday, at Dewsbury, W. Knowles, of Hanging Heaton, was brought up on a charge of wilfully and falsely pretending to be a surgeon, and taking the name and using the title of surgeon, implying that he was registered under the Medical Act. Mr. William Wiseman, surgeon, was the complainant, and it appeared the defendant was formerly an assistant in his service. He had selected three out of at least fifty cases which had come to his knowledge in which the defendant had signed certificates of the deaths of patients, and styled himself a surgeon. The evidence being conclusive, the defendant, by the advice of his attorney, withdrew his plea of not guilty, and admitted the three offences proved against him. Fines amounting to ten guineas were imposed, with the alternative of three months' imprisonment.—*Yorkshire Post.*

**SUNDAY LIQUOR TRAFFIC.**—The Earl of Derby received a deputation on Wednesday evening, February 27th, at his official residence in Downing-street, which had been appointed by a large meeting of working men in the Lambeth Baths, on Friday last, to plead with him against the sale of intoxicating liquors on Sunday. The deputation was introduced by the Rev. John Garrett, D.D., and was accompanied by Archbishop Manning, Rev. Newman Hall, Mr. Bazley, M.P., and Dr. Ellis, and consisted of representatives of every branch of trade. His lordship after listening attentively to the various speakers expressed much satisfaction at having received such a deputation, saying it was a question first for the House of Commons; that the Government could not undertake the anxiety of introducing such a measure, and advising rather that it should be introduced by an independent member of Parliament. The deputation then withdrew, expressing their thanks to his lordship for so kind and satisfactory a reception of their request.

**THE POOR-LAW MEDICAL OFFICERS.**—On Wednesday last a large number of the metropolitan Poor-Law medical officers met at the Freemasons' Tavern to consider the provisions of the Metropolitan Poor Bill. Dr. Rogers, of the Strand Union, presided, and there were present many gentlemen interested in Poor-Law questions as visitors. Letters of apology were read from Mr. Thomas Hughes, M.P.; Mr. Devonport Bromley, M.P.; and others. And the honorary secretary, Dr. Dudfield, read a very able report upon the bill, which was generally approved, and it said, "No part of this statesmanlike scheme has excited more lively pleasure than the clauses which propose to put the treatment of the outdoor sick poor upon a proper footing. Efficient medical attendance, together with adequate relief, would keep many a family out of the workhouse, and so largely tend to diminish pauperism. For it is too true that the first plunge is all that is dreaded in this case as in many others; and the honest poor man who shrinks from the thought of entering the workhouse for the first time, after he has taken that fatal step is too prone ever after to regard the house as an easy resource in time of difficulty, and as a comfortable home—so pernicious is the loss of a proper sense of independence." The chairman moved the adoption of the report, and in doing so detailed the struggles the Poor-Law medical officers had, for a period extending over eleven years, maintained against the guardians in the endeavour to obtain rights for themselves and the proper necessities for the sick under their charge. He then referred to the establishment of the Association for assisting the Sick Poor in the London Workhouses, and dwelt upon the vast good which that association by the assistance of the press had been able to accomplish in a very short time. He also referred to the labours of Dr. Anstie, Dr. Carr, and Mr. Ernest Hart, in visiting and reporting upon the London workhouse infirmaries, and said the value of those reports was to be seen in the great exposures which had followed as to the management of those workhouses. He expressed himself as greatly pleased with Mr. Hardy's Bill, but urged [that, there were points which would have to be considered in committee. Dr.

Welsh seconded the adoption of the report, which was carried unanimously. Dr. Dudfield then moved the following resolution:—"That this meeting is of opinion that Mr. Hardy's Metropolitan Poor Bill will effect considerable improvement in the medical care and treatment of the sick poor; and they recognize with great satisfaction that it embodies nearly all the recommendations suggested by this association." Mr. Eugene Goddard seconded the motion, which, with an addendum proposed by Dr. Fowler, seconded by Dr. Carr, that all the charges of the indoor sick poor should be defrayed out of the common fund, was carried unanimously. Resolutions were also carried that the Bill should be watched, and endeavours made to obtain life appointments for medical officers and for other purposes, and the proceedings closed in the usual manner.

MR. BAXTER LANGLEY, of Lincoln's-in-fields, has been appointed receiver under the High Court of Chancery in accordance with a decree in the case of *Brighthouse v. Margetson*.

## Notices to Correspondents.

The Titles and Contents for Vol. II. are issued with this Number. Communications to the London Editor should be addressed to 20 King William-street, Strand; to the Edinburgh Editor, at Maclachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

### MEDICAL VACANCIES.

Andover Union—Medical Officers for No. 4 and No. 5 Districts.  
Cheshire Lunatic Asylum—Assistant Medical Officer.  
Chorlton Union—Assistant Medical Officer for the Workhouse, Withington.  
Islington Dispensary—Resident Medical Officer.  
Lambeth Workhouse—Resident Medical Officer.  
St. Giles and St. George, Bloomsbury—Assistant Medical Officer.

### MEDICAL APPOINTMENTS.

T. BAKER, M.R.C.S.E., has been appointed Medical Officer for the Roberts-bridge District of the Ticehurst Union, Sussex.  
G. CARPENTER, M.R.C.S.E., has been appointed Medical Officer to the Workhouse of the Castlecomer Union, Co. Kilkenny, vice C. E. Ross, M.B., deceased.  
T. DANDY, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the Rufford District of the Ormskirk Union, Lancashire, vice C. Dandy, M.R.C.S.E., deceased.  
R. GOODING, M.B., has been appointed a Surgeon for the Greenwich District of the Royal Kent Dispensary.  
G. F. HARDEN, M.B., has been elected House-Surgeon of the Bolton Infirmary and Dispensary.  
W. HARDY, L.R.C.P.E., L.M., M.R.C.S.E., has been appointed Medical Officer to the Portsmouth District of the Portsea Island Union.  
JAMES NEAL, M.D., has been appointed Honorary Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for Diseases of Women and Children, vice J. Archer; F.R.C.S.E., resigned.  
H. R. PALMER, M.R.C.S.E., has been appointed a Surgeon for the Greenwich District of the Royal Kent Dispensary.  
J. R. PERRINS, L.R.C.P.Ed., L.S.A., has been appointed Resident Medical Officer to the Sick Children's Hospital, vice W. O. P. Nolston, M.D., whose appointment has expired.  
H. M. TUCKWELL, M.D., has been appointed Consulting Physician to the Warneford Asylum, Oxford, vice G. W. Child, M.D., resigned.  
G. WATSON, M.D., has been appointed House-Surgeon to the Dumfries and Galloway Royal Infirmary, vice John Smith, M.B., C.M., resigned.  
S. WOODCOCK, L.R.C.P.Ed., has been appointed Medical Officer for the No. 1 District of the Chorlton Union, vice John Smith, M.R.C.S.E., resigned.

### MEDICAL DIARY OF THE WEEK.

THURSDAY, MARCH 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS—Operations, 10½ A.M.  
CENTRAL LONDON OPHTHALMIC HOSPITAL—Operations, 1 P.M.  
ST. GEORGE'S HOSPITAL—Operations, 1 P.M.  
UNIVERSITY COLLEGE HOSPITAL—Operations, 2 P.M.

LONDON SURGICAL HOME—Operations, 2 P.M.  
WEST LONDON HOSPITAL—Operations, 2 P.M.  
ROYAL ORTHOPEDIC HOSPITAL—Operations, 2 P.M.  
ROYAL INSTITUTION—3 P.M. Prof. Frankland, "On Coal Gas."  
HARVEIAN SOCIETY OF LONDON—8 P.M. Dr. Tilbury Fox, "On Parasitic Diseases of the skin, and on a Case of Fibroid Molluscum associated with Kelis."

FRIDAY, MARCH 8.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS—Operations, 10½ A.M.  
WESTMINSTER OPHTHALMIC HOSPITAL—Operations, 1½ P.M.  
ROYAL COLLEGE OF SURGEONS OF ENGLAND—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Saurapsida, or Reptiles and Birds."  
ROYAL COLLEGE OF PHYSICIANS—5 P.M. Croonian Lectures: Dr. Andrew Clark, "On the States of Lung commonly comprehended by the term Pulmonary Phthisis."  
ROYAL INSTITUTION—8 P.M. Rev. W. Greenwell, "On the Yorkshire Wold Tumuli."

SATURDAY, MARCH 9.

ST. THOMAS'S HOSPITAL—Operations, 9½ A.M.  
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS—Operations, 10½ A.M.  
ST. BARTHOLOMEW'S HOSPITAL—Operations, 1½ P.M.  
KING'S COLLEGE HOSPITAL—Operations, 1½ P.M.  
ROYAL FREE HOSPITAL—Operations, 1½ P.M.  
CHARING-CROSS HOSPITAL—Operations, 2 P.M.  
ROYAL INSTITUTION—3 P.M. Prof. Frankland, "On Coal Gas."

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

PATERSON.—On the 18th of Jan., at Kurnaul, East Indies, the wife of Dr. H. F. Paterson, Royal Artillery, of a daughter.  
SPEEDY.—On the 25th of Jan., at Poonah, Bombay, the wife of Dr. Speedy, Surgeon 45th Regiment, of a daughter.  
GOODING.—On the 11th ult., at Sussex-place, Cheltenham, the wife of J. C. Gooding, M.D., of a daughter.  
WIGLESWORTH.—On the 15th ult., at Brougham-terrace, Liverpool, the wife of Arthur Wiglesworth, Surgeon, prematurely, of a son.  
HUGHES.—On the 20th ult., at Forney, the wife of W. F. Hughes, M.R.C.S.E., of a daughter.  
WILKINSON.—On the 23rd ult., at Aston-road, Birmingham, the wife of A. G. Wilkinson, M.R.C.S.E., of a son.  
LORD.—On the 25th ult., at Victoria-place, Crewe, the wife of Richard Lord, M.D., of a daughter.

### MARRIAGES.

ADLEY—BURNBY.—On January 19th, at Barrackpore, Calcutta, W. H. Adley, Surgeon, 17th Bengal Cavalry, to Evelina Ross, younger daughter of Major-General G. Burney, Bengal Army.  
ARMSTRONG—PRATER.—On February 19th, at the parish church, Woolwich, J. C. Armstrong, M.R.C.S.E., of Gravesend, to Annie, second daughter of A. Prater, M.D., of Barrington-villas, Shooter's-hill.  
HEAD—CLEAVE.—On February 20th, at St. Brook, R. L. B. Head, Surgeon, R.N., to Lizzie, daughter of T. Cleave, Esq., Trevanion, Cornwall.  
JONES—EDSFORTH.—On February 19th, at the parish church, Wyresdale, Dr. Jones, of New Malton, Yorkshire, to Mary, fourth daughter of the late Eidsforth, Esq., Poulton Hall, Lancaster.  
OAKES—KELLETT.—On February 20th, at Ballyconnell, County Cavan, F. A. Oakes, Staff Surgeon, to Anna Selina, eldest daughter of the Rev. O. S. Kellett, Esq., Rector of Tomregan, Cavan.  
THURSFIELD—WILLIAMS.—On February 14th, at Llandudno, T. G. Thurstfield, M.D., Broseley, Salop, to Anne Catharine, eldest daughter of John Williams, Esq., Bodofon.  
WOTHERSPOON—PRIMROSE.—On February 27th, at 24, Royal-crescent, by the Rev. Dr. M'Ewen, assisted by the Rev. John Moodie, William Wotherspoon, L.F.F. & S. Glasgow, to Jessie McFarlane, only daughter of Peter Primrose, Esq.  
KELSO—RANKING.—On Jan. 10th, at St. John's Church, Trichinopoly, by the Rev. Octavius Dene, B.A., John Andrew Kelso, Esq., Lieutenant Royal Artillery, to Marion, daughter of William Harcourt Ranking, M.D. Cantab., F.R.C.P.L., and niece of J. L. Ranking, Surgeon-Major and Acting Garrison Surgeon, Trichinopoly, Madras.

### DEATHS.

MEGGY.—On the 6th Jan., at Uitenhage, Port Elizabeth, South Africa, F. Meggy, M.R.C.S.E., formerly of Park-crescent, Stockwell, aged 28.  
OWEN.—On the 15th ult., at Fitzroy-square, J. L. Owen, M.D., late of Brooklyn, New York, and of Carnarvon, aged 50.  
MONDAY.—On the 16th ult., in London, J. R. Monday, M.R.C.S.E., of Olveston, near Bristol.  
LOWE.—On the 18th ult., at Worcester, Edgar Lowe, M.R.C.S.E., Surgeon in the Gloucestershire Militia, aged 36.  
EVANS.—On the 18th ult., at Narberth, Jessie James, the wife of Maurice Griffith Evans, M.D., and youngest surviving daughter of the late Evan George, Esq., of Plas Crwn, in the County of Pembroke.  
MORRIS.—On the 21st ult., Wm. Morris, M.R.C.S.E., of Tudor-road, Upper Norwood, formerly of Camberwell, New-road, aged 66.  
FERGUSON.—On the 2nd inst., at Ailsa-cottage, Girvan, Ayrshire, of bronchitis, William, infant son of Alexander Fergusson, L.R.C.P. Ed., &c.

## INSURANCE.

## INDIA AND THE COLONIES.

**THE STANDARD LIFE ASSURANCE COMPANY,** with which the **COLONIAL LIFE ASSURANCE COMPANY** is now amalgamated, affords the greatest facilities for effecting Assurances on the Lives of Persons proceeding Abroad.

Local Boards and Agencies in each Colony, where Premiums are received and Claims settled.

Moderate Premiums, at Rates suited to each Climate.  
Immediate reduction to Home Rates on return to Europe or other temperate climate.

Loans advanced to Civilians and Military Officers.

Profits divided every Five Years.

Annual Income of the Company upwards of £650,000 sterling. Invested Capital and Accumulations upwards of £3,500,000.

## BOARD OF DIRECTORS IN DUBLIN:

CHAIRMAN OF THE BOARD,

The Right Hon. Lord DUFFERIN AND CLANEBOYE.

DIRECTORS.

Joseph Boyce, Esq., J.P., D.L., Deputy-Chairman.

Sir Edward Borough, Bart., Deputy-Chairman.

James Stirling, Esq., Ballawley Park, Dundrum.

J. D. LaTouche, Esq., Dundrum.

The Hon. St. John Butler.

Robert P. Bayley, Esq., J.P., Rookwood.

C. G. Burke, Esq., Master of the Common Pleas.

WILL. THOS. THOMSON, *Manager.*

WILLIAM BENTHAM, *Resident Secretary.*

DUBLIN—66, UPPER SACKVILLE-STREET.

Edinburgh—3, and 5, George-street.

London—82, King William-street and 3, Pall-Mall, East.

## UNIVERSITY LIFE ASSURANCE SOCIETY.

EXTENSION TO FOUNDATION SCHOOLS.

Additions in 1885 at the rate of 1½ per cent. per annum.

CHARLES McCABE, *Secretary.*

24, Suffolk-street, London, S.W.

## APOTHECARIES' HALL, LONDON.

NOTICE IS HEREBY GIVEN that, at a Meeting of the Court of Examiners of the Society of Apothecaries, on the 14th instant, the following resolution was agreed to:—

“That the Court of Examiners refuse to receive any Certificates of Lectures, or of Anatomical Instructions, delivered in private to particular Students, apart from the ordinary Classes of public, recognised, Medical Schools.”

W. P. BRODRIBB, *Secretary*  
to the Court of Examiners.

February 25th, 1887.

## LONDON NURSES' INSTITUTE.

42, South Audley-street, Grosvenor-square, W.

**T**RAINED NURSES (Medical, Surgical, Mental and Monthly) can at all times be obtained from this Institute.

Hospital Appointments by special arrangement.

Letters and Telegrams should convey the nature of the case to be attended.

T. HAMILTON, *Manager.*

## LISNASKEA UNION.

## Brookeborough Dispensary District.

**I**N consequence of the resignation of Dr. McGOWAN, the Committee of Management of the above Dispensary will, at their Meeting to be held in their Committee-room in Brookeborough, on *Tuesday, 19th March, instant*, at the hour of Two o'Clock, proceed to the Election of a Medical Officer for the above District, whose qualifications must be in accordance with the recent orders of the Poor-Law Commissioners.

Salary, as Medical Officer, £100 per annum.

All applicants must appear in person on the day of Election, and will be required to present their Diplomas and Testimonials to the Committee on that day.

By Order,

MATT. H. SANKEY, *Hon. Sec.*

LURGANEHRAE, BROOKEBOROUGH,  
2nd March, 1887.

The private practice and Registration Fees have been found to exceed the sum of £150 during the last year.

## MEDICAL CHORAL SOCIETY.

FOUNDED A.D. 1866.

Patron:

LORD TALBOT DE MALAHIDE.

President:

T. E. BEATTY, Esq., M.D., F.R.C.S.I.

Vice-Presidents:

E. HAMILTON, Esq., M.B., F.R.C.S.I.

R. M'DONNELL, Esq., M.D., F.R.S.

S. WILMOT, Esq., M.D., F.R.C.S.I.

C. P. CROKER, Esq., M.D., F.K.Q.C.P.

J. MORGAN, Esq., F.R.C.S.I.

E. P. WRIGHT, Esq., M.D., F.R.C.S.I.

W. COLLES, Esq., M.B., F.R.C.S.I.

W. O'B. ADAMS, Esq., M.B., F.K.Q.C.P.I.

A. H. JACOB, M.D.T.C.D., F.R.C.S.I.

Committee:

E. D. MAPOTHEE, Esq., M.D., F.R.C.S.I.

W. J. HEPBURN, Esq., L.R.C.P. & S. Edin.

W. B. PEARSALL, Esq., L.R.C.S.I.

R. M. CRAIG, Esq., L.R.C.S.I., L.K.Q.C.P.I.

B. J. NEARY, Esq., L.R.C.S.I., L.K.Q.C.P.I.

J. A. BAKER, Esq., F.R.C.S.I.

C. MAYNE, Esq.

E. MATHEWS, Esq., jun.

H. CARDEN, Esq.

C. BELL, Esq.

W. CONALLY, Esq.

J. ALEXANDER, Esq.

Hon. Secretary:

T. W. HIME, Esq., A.B., Steevens' Hospital.

Treasurer:

R. KELLETT, Esq., Steevens' Hospital.

Conductor:

W. HOUGHTON, Esq.

This Society has been formed for promoting the Study of Music among the Members and Students of the Medical Profession.

All Members and Students of the Medical Profession are eligible for election as Members of the Society.

Weekly Practise Meetings are held in the Schoolhouse adjoining St. Anne's Church, Molesworth-street, under the superintendence of the Conductor.

It is proposed to give at least two Concerts each Session.

The Annual Subscription of One Guinea entitles the Subscriber to Two Tickets for each Concert.

The Subscription for Performing Members is 5s. per Quarter. Performing Members require to be proposed, seconded, and balloted for.

N.B.—Gentlemen desirous of becoming Members can learn all particulars by applying to the Secretary.

## SURGICAL SOCIETY OF IRELAND.

**T**HE Meetings of the Society for the Session 1866-67 will take place at the Royal College of Surgeons, on the undermentioned Evenings, at Half-past Eight o'clock precisely:—

1867.—Friday, 15th March.

„ Friday, 29th March.

„ Friday, 26th April.

Members who intend to read Papers before the Society are requested to inform the Secretaries, in writing, of their intention a few days previously.

Discussion on any Paper is not permitted unless the writer calls for it or desires it.

When the Contributor of a Paper wishes that the Secretaries should read it to the Society, he will please forward it to them some days before the Meeting.

Except under special circumstances, no Member can be permitted to occupy the Meeting in reading a Paper for a longer period than half an hour; and the Society will not be held responsible for any opinions advocated in the communications read. Neither can a Member be allowed to speak for more than ten minutes, during a debate relative to a communication.

After a Paper has been read it becomes the property of the Society, for publication in its proceedings.

The exhibition of recent morbid specimens is allowed precedence of all other communications; but a specimen cannot be considered a recent one unless it has been removed from the body within the fortnight immediately antecedent to the Meeting.

Each Member of the Society, being a Subscriber of 5s. to the Refreshment Fund, is entitled to as many Tickets for Visitors as he may require, at 6d. each.

Naval and Military Surgeons are admitted as Honorary Members of the Society on sending their names to the Secretaries.

None but Physicians or Surgeons are admitted to the Meetings of the Society.

CHARLES BENSON, M.D.,

B. WILLS RICHARDSON, F.R.C.S.I.,

} *Honorary Secretaries.*

Oration.

THE ANNUAL ORATION FOR 1867,

DELIVERED AT THE

HUNTERIAN SOCIETY,

HELD AT THE LONDON INSTITUTION.

By WILLIAM SEDGWICK SAUNDERS, M.D.,

CONSULTING-PHYSICIAN TO THE SCINDE AND DELHI, EAST INDIAN, BOMBAY AND BARODA, GREAT SOUTHERN OF INDIA AND CALCUTTA, AND SOUTH-EASTERN RAILWAY COMPANIES; VICE-PRESIDENT HUNTERIAN SOCIETY; TREASURER TO NEW SYDENHAM SOCIETY; MEDICAL EXAMINER TO MUTUAL LIFE OFFICE, ETC., ETC.

(Continued from page 208.)

THE process is said to have cost £300 of our money, and was, of course, only applicable to the rich. The fee for embalment alone, varied from a talent (which has been estimated by some as equivalent to £193 15s., and by others to £243 15s. of our present money) to a mina, in value about £3 4s. 7d.

The embalment of the middle classes was, in some degree, regulated by their means; the simplest form being, the destruction of the intestines with strong oil of tar, and after their removal soaking the body in a strong solution of nitre for a period not exceeding seventy days.

Some have ascribed the practice of embalming to the fact of the periodical inundations of the Nile, rendering interment impossible at such seasons, and hence have thought that necessity had quite as much to do with the custom as the religious principle; but this idea is not well founded. The Nile continues to overflow, but embalming has ceased for ages.

After Hippocrates the name of Aristotle comes before us. Aristotle was the pupil and friend of the venerable Plato, whose doctrines he adopted and developed: he lectured at Athens 370 years before Christ. As a physician and naturalist he was far in advance of his contemporaries, and as a mathematician and moral philosopher, his transcendent learning was, for ages, the theme of every scholar; and his "System of the Universe" was adopted by the whole of the civilized world. These great qualities attracted the attention of Philip of Macedonia, who chose him as the tutor of his son Alexander (the Great). Ignorance and superstition were, however, omnipotent, and for having enunciated the doctrine of one God, and a supreme first cause, the priests of the various temples seeing their craft in danger, excited the populace, who threatened his life. Warned by the fate of Socrates, he retired to Chalcis to wear away a life embittered by personal suffering, and sorrow for the folly and ingratitude of his countrymen.

The heart's deepest feelings are roused at the remembrance of the deeds of violence perpetrated against every benefactor of mankind who has had the courage to promulgate truths beyond the comprehension of the vulgar on the one hand, and opposed to the vested interest of established errors on the other. The fate of Aristotle is a common result, not confined to the dark ages, not without examples amongst ourselves.

The learned Philo of Alexandria, who lived A.D. 40, has given us an interesting account of the very remarkable sect living in Egypt in his day, known as the "Therapeutæ," or "healers." He describes them as a confraternity who, after having received a special training in the University of Alexandria, devoted themselves to the healing art; they led a secluded, contemplative life, and laid the foundation of the monastic system. Eusebius calls them Christians, but this is not confirmed by Philo, who was a member of the sect; they were, probably, Platonists, or philosophical pagans. They ascribed their cures to prayers, fastings, and incantations, eschewed all material remedies and medicaments; but made free use of magical rites of both forms—the leucomancy, or white magic, used in invoking the gods, and necromancy when the demons were to be propitiated or coerced. St. Luke, before his conversion, is supposed to have been a Therapeut; and St. Paul denounces some of

their errors. Of their faults we cannot judge, but we may admire the benevolence with which they devoted themselves alike to the physical and moral welfare of their fellow men—in this respect, no unworthy forerunners of Him who commanded his disciples, not only to "instruct the ignorant," but to "heal the sick."

We pass over three centuries to come to the time of Celsus, who, in the reign of Tiberius, and the first century of our Lord, was established at Rome; where he acquired great honour and renown. To these he was fairly entitled by the extent of his learning and the especial attention he paid to surgery and medicine. His principles governed the medical world without a rival until the time of Galen, who divided the empire with him for centuries.

Celsus was the first native Roman physician whose name has been transmitted to us. The practice of medicine and surgery being prior to his time in the hands of eminent Greeks and Asiatics, excepting that there existed in Rome (at that period) a race of native practitioners, who belonged to the class of slaves or persons of low degree; and to whom were entrusted only the subordinate branches of the healing art.

The great proficiency of Celsus on the subjects of rhetoric, philosophy, military tactics, and rural economy, as mentioned by Quintillian, has induced many of our older writers to doubt whether he ever really practised medicine and surgery, or, whether, like the elder Cato, he simply studied them as a branch of general knowledge; and this scepticism has been favoured by the fact of his name being omitted by Pliny, in his "Treatise on the History of Medicine." On the other hand, no one, I think, can rise from the perusal of his celebrated work, "De Medicina," without being thoroughly convinced that his intimate acquaintance with the theory and practice of medicine, surgery, and pharmacy could only have resulted from close bedside observation.

Galen was born at Pergamos, in Asia, in the second century; his learning was great, and his literary labours enormous. Having traversed Egypt and Greece, and acquired a knowledge of every science taught in the schools there, he settled in Rome. His works have been estimated at over 300 volumes—medical, physical, and meta-physical.

Galen bled more frequently than his predecessors, but he gave very careful directions as to the conditions under which venesection should be resorted to, as well as to the quantity of blood to be taken.

Averroes, Avicenna, and other Arabian physicians held him in great veneration; and Dr. Alison says:—"For centuries after his death his doctrines and tenets were regarded in the light of oracles, which few persons had the courage to oppose; and the authority of Galen alone, was estimated at a much higher rate than that of all the medical writers combined, who flourished during a period of more than twelve centuries.

Rome, in its decadence, was too much occupied with the intrigues and villainies of the factions by which it was ultimately destroyed, to spare any time for the culture of science. It was not until after the total disappearance of the Eastern Empire, and the hollow tranquility which succeeded the triumphs of Mahomet, and the subsequent subjugation of Spain by the Moors, that learning reared its head in Alexandria, and the Arabian physicians came into view.

Although Greece had disappeared, even in the noonday of its glory, its literature never possessed more devoted admirers, nor more faithful exponents than are to be found among the Arabian philosophers, and yet what a striking contrast is exhibited in the characters of the two people. Whilst making the philosophy of Greece their own, they by no means lost their distinctiveness and individuality. The Greeks delighted in all that was brilliant and fascinating, like the beautiful scenery of Attica and Asia Minor. The Arabs were thoughtful and grave, monotonous and arid, like the deserts they inhabited. The genius of poetry illumined all the meditations of the former, and their thoughts were graceful, even in their errors, whilst the reflections of the latter were dull and melancholy, albeit they were based on truths.

A dreary night now ensues—we have no name of note until Paulus Ægineta in 640: but what a series of historically grand events interpose: The invasion of Europe by the Huns—Division of the Roman Empire—Taking of Rome by Alaric—Visigoths established in Spain—Saxon heptarchy begun—Conquest of Italy by Totila—Birth of Mahomet, down to the taking of Alexandria by the Arabs—Greece and Rome having virtually disappeared; and our next author (Paulus) probably present at the burning of the great library.

Paulus Ægineta is entitled to our homage, as the author of an abridgement of the works of Galen, and many excellent treatises on medical subjects, especially on those incident to childbed and the diseases of women; he lived in the seventh century, and his labours have been thought worthy of being translated by the Sydenham Society. Paulus Ægineta was the first writer upon *small-pox* and *measles*, and the originator of the theory of *zymosis*, which has received so much attention of late. He died about the middle of the seventh century, and with him expired the last of the Greek writers upon medicine.

Avicenna, who lived in the year 980, deserves a fuller notice than we can afford him; his works are said to present great clearness and acuteness. At the early age of eighteen he was chosen Physician to the Court of the Caliph of Bagdad, where for some offence he was imprisoned, and ultimately died. He has been called the "Hippocrates of the Arabs."

Rhazes was contemporary with Avicenna, and has attracted the respectful attention of the lovers of ancient medicine. His most esteemed work is a treatise on small-pox, which was translated by Dr. Mead in 1548.

I will conclude these sketches of the Arabian schoolmen with a brief notice of Averroes, the most eminent of them:—

This profound scholar was born at Cordova, in Spain, of which city his father was the alcade, about the year 1120. He was educated in Morocco, then in its glory, and in the celebrated schools there studied law, philosophy, and medicine. His admiration for Aristotle was unbounded, and his unwearied application to the examination of that great man's works, secured for him the reputation of the ablest commentator on the Aristotelian philosophy. He rose to the dignity of a judge in Morocco, but the freedom of his opinions being in advance of the age, he was imprisoned for some years, and only released on recanting his errors; he died 1206 during the Caliphate of Almanzer.

The glories of the Moorish power now began to wane, and after repeated discomfitures in 1516, that intelligent and highly civilized people were finally expelled by Ferdinand the catholic: the cross triumphs—the crescent retires, and takes with it all that is admirable in arts, or humanizing in science; the Spaniard has chased away Mahomet, and receives the Inquisition as the first-fruits of his conquest.

The war against opinion was carried on so vigorously that Copernicus, whose acute perception had discovered the errors of Aristotle's theory of heavenly bodies, was fiercely denounced. Copernicus was born in Westphalia in 1473, he studied at Cracow, where he received the degree of Doctor of Medicine; at Bologna his piercing genius discovered that the sun was the centre of the planetary system, that the earth was a planet and revolved round the sun like other planets, and thus was first made known the true system of the universe. Being distasteful to the church, the Pope issued a sentence of excommunication; and he died with a heart oppressed by such unmerited persecution.

These discoveries were further pursued by another learned physician, Galileo, who was born at Pisa in 1564. He entered the University there in 1581, and prosecuted his studies with such zeal and success, that in a very few years he became Professor of Mathematics. He now began his career as a teacher of the philosophy of Copernicus, and soon received unpleasant evidences that the disciple of truth must be ready to suffer. A congregation of cardinals, monks, and mathematicians of the old school, deter-

mined that his works were heretical and dangerous, and the holy inquisition sentenced him to prison. After remaining incarcerated some months he was taken before his judges, and required to renounce his errors, and with his hand upon the Gospel, to swear that they were sinful and detestable. Having performed this horrid penance, his conscience upbraided him, and as he rose from his knees, he exclaimed, "yet it does move," for which relapse he was further sentenced to perpetual imprisonment. He continued thus excluded for many years, during which time blindness, deafness, and pains in his limbs embittered his existence, and death at length, more merciful than the Holy See, released him from his trials. Newton was born in the year this noble martyr died.

For the edification of the worshippers of the "good old times," a few more instances of the loving kindness which prevailed may be acceptable.

The clerical sages of the University Salamanca pronounced that the assertion of Christopher Columbus, that a continent existed beyond the seas, was blasphemous and feloniously wicked. A Bishop of Salisbury expressing his belief in the existence of the antipodes was denounced by the Bishop of Mentz as a dangerous heretic, and committed to the flames.

Bigotry, however, is not confined to any one creed, since we know that Calvin the reformer, a man who had suffered persecution "without learning mercy," no sooner finds himself invested with the power to punish the freedom of thought which he had himself indulged in, than he persecutes to death the learned physician Michael Servetus, not for any immoral proclivity, but because he believed him to be unsound on the doctrine of the Trinity. Servetus took his degree of Doctor of Medicine at the University of Paris about the year 1535. He is the author of some medical treatises on the circulation of the blood, and also translated Ptolemy's geography; he was for some time in constant correspondence with Calvin, but as the "Odium theologicum" is the bitterest, Calvin shewed his christian charity by causing his antagonist to be consigned to the flames.

But I must hasten forward, Fallopius looms in the distance, and with him the men come fast and numerous. Gabriel Fallopius was born at Modena about the year 1523, and was one of the great triad of anatomists in Italy, who laid the foundation of the modern science of anatomy at the latter end of the 16th century. Fallopius succeeded Vesalius in the chair of anatomy and surgery at Padua in 1557. His career was brilliant but short, and he died in 1562. It should be mentioned that Fallopius shared the usual fate of great discoverers; his originality was disputed, and his learning questioned; but it has been always so, and in appreciating the works of our predecessors, we must keep in view the enormous difficulties by which every onward step, whether in art or science, is beset.

"Envy doth merit, as it shade pursue." Truth does indeed ultimately prevail, but too frequently the heart of the discoverer is broken before the obtuseness of the mediocrities in power, by whom it is obstructed, can be overcome.

Although a little diverging from the strict chronological order, I must here introduce to you our old acquaintance Paracelsus; this eccentric genius had too little virtue to be admired, and too much talent to be despised. He was born at Zurich, in Switzerland, in 1493, and was consequently contemporary with many more learned, but less celebrated men; an unblushing and presumptuous egotist, he presents himself in a moral point of view, the exact antithesis of the amiable and virtuous Hippocrates. That he made some very useful discoveries must be granted to him; he introduced the use of opium into Germany, and was the first practitioner who employed preparations of mercury, antimony, sulphur, iron, and other remedies.

Van Helmont is the most indulgent of his biographers, and Lord Bacon the most severe; but perhaps the description given by Zimmerman comes nearest the truth—"Paracelsus burnt publicly at Bale the works of Galen, Avicenna, and other eminent predecessors, because, he said, 'they

knew nothing of the cabbala and magic,' which lay at the root of all medical and natural laws. He undertook to cure all diseases by the use of certain words and charms. He enjoined secrecy on his disciples, and certainly was the first *great quack* from whom the numerous band of Charlatans have proceeded."

He has left his mantle behind him, and his descendants, with none of his brains, have largely inherited his presumption. On the occasion of his inauguration in the Chair of Medicine he thus expresses himself:—

"Know," says he "that my *cap* has more learning than all your professors, and my beard more experience than all your academics! I speak to you Greeks, Latins, Frenchmen, Italians, &c., &c. You will follow me, I shall not follow you. You, I say, doctors of Paris, Montpellier, Dalmatia, of Athens, you Jews, Arabs, Spaniards, English, I tell you all that nature obeys me; and if God does not deign to assist, I have yet the devil to resort to. I am king of all science, and command all the hosts of hell."

We have in this impostor the very embodiment of the true quacks of to-day; their language is indeed a little subdued, but their pretensions are as large; and, let me add, that whereas Paracelsus, in his days, had the countenance and support of many persons of rank, so in ours, there does not exist an ignorant pretender without the patronage of the great, and this patronage, too often, in the exact ratio of his presumption and falsehood.

It must not be overlooked that this arch impostor died miserably, in poverty, induced by dissipation, and the possessor of the elixir of immortality breathed out his drunken soul at the age of fifty.

We have a lively picture of the state of things begotten by this man in the pages of Burton, an example in himself of the power of credulity, and a proof that great scholastic learning was by no means at variance with the wild vagaries of the times.

Let me offer you one specimen on the subject of demoniacal possession, first introducing you to a new character, Cornelius Gemma, who was born at Louvain in 1535, and was one of the greatest scholars of his age, a professor of medicine in his native town (the chair having been conferred upon him by the great Duke of Alva, who governed the Low Countries), and whose writings embrace the subjects of medicine, mathematics, magic, and spiritual possession. Like Cardan, he was thought a little extreme in some views, but this one example suffices to demonstrate the evil influences of Paracelsus. Gemma, in his second book on natural miracles, says:—"A young maid called Katherine Gualter, a cooper's daughter, in the year 1571, had such strange passions that three men could not hold her. She purged a live eel—I myself saw and touched—a foot and a half long; she vomited twenty-four pounds of fulsome stuff of all colours twice a-day for fourteen days, and after that great balls of hair, pieces of wood, pigeons' dung, coals, and after them two pounds of pure blood, and then again coals and stones (of which some had inscriptions) bigger than a walnut. All this I saw with horror. Physic could do no good, so she was handed over to the clergy."

Marcellus Donatus relates a story of a country fellow who had four knives in his belly, every one a span long, and indented like a saw; also a wreath of hair, and much other baggage. How they came "into his guts" he knew not.

Burton lived about 1576, and was consequently of the same age as our great Harvey, of whom we have now to speak. Before we proceed, however, it will not be out of place to notice the general belief in astrology, and especially lunar influences which prevailed at this period. Herbs and roots had their several patrons, and it was only when gathered and preserved under certain prescribed circumstances that their specific virtues were assured.

This superstition is not yet extinct; even in this year of grace, 1867, we are not quite emancipated from the ignorance of the primeval ages, and it is not a very unusual thing to see an advertisement in the *Times* announcing a "child's caul" for sale. These and such-like absurdities,

"though it make the unskilful laugh, cannot but make the judicious grieve."

Nor is this credulity confined to the illiterate classes. The dupes of St. John Long, as many of us may remember, included "potent, grave, and reverend seniors," and on his memorable trial, a certain noble lord gave evidence that Mr. Long had extracted a piece of lead from his head. Some scoffers think it a pity that the quack, having succeeded to some extent, left so much behind.

In speaking of Harvey, it is difficult to strike out any new path in a tale that has been told so often. Yet, we may extract something out of the consideration of the times in which he lived, and the men by whom he was surrounded. He was born at Folkestone, in 1578, and commenced his travels at 19 years of age. What his previous education had been does not appear, but we find him at the age of 24 elected Doctor of Medicine at Padua—then the most famous University in the world. On his return to England he received the honour of Doctor of Medicine at Cambridge. James the First, and his son, Charles the First, favoured him with their countenance, and in 1628 he was induced to publish an account of his great discovery. As a matter of course he was at once denounced as a visionary; personal abuse was unsparingly poured upon him; but, as the grand fact enunciated was not to be shaken, his enemies turned round and discovered that, after all, it was not new, and had been the doctrine of many eminent physicians from the earliest days. The old, old story: the same sickening detraction—the same miserable envy rife in every age and clime. Harvey died in 1658.

The College of Physicians in London owes its foundation to Dr. Thomas Linacre, of All Souls, Oxford, a man of profound learning, who had won honours at Rome, Bologna, and Florence.

Linacre, through his interest with Wolsey, a wise and liberal patron of learning, obtained, in 1518, letters patent from Henry the Eighth, constituting a corporate body of regular Physicians in London. He was elected the first president, and meetings were held at his house in Knight Ryder-street until his death. With a munificence not without many worthy imitators in our profession, as we shall presently point out, he bequeathed this house to the College.

Harvey was elected president of the College of Physicians in 1654, but excused himself on account of his age and infirmities. Such, however, was his attachment to that body (best evinced by *donationes inter vivos*), that, in 1656, he made over his personal estate in perpetuity for its use, having previously (on the occasion of the College being removed from Knight Ryder-street to Amen-corner) built them a library and public hall (now the site of Stationers' Hall), which he granted for ever, together with his private library and valuable collection of instruments. He died in 1658.

I may here mention that, after the fire of London, the College of Physicians was rebuilt on a site in Warwick-lane, formerly called Eldenesse-lane, until the erection of the palatial residence of Guy of Warwick, the King-maker.

Sir Christopher Wren was the architect of the new College, and its burnished dome gave Pope the opportunity of displaying his powers of satire thus—

"Witness a dome, majestic to the sight,  
And sumptuous arches bear its oval height;  
A golden globe, placed high, with artful skill,  
Seems to the distant sight—a gilded pill."

Shortly after the death of Sydenham came Dr. Freind, who was born in 1675. Being a man of worth and learning, he soon acquired a leading position in his profession, and, having devoted himself early in life to the study of politics, he was returned to Parliament as member for Launceston, where, having warmly espoused the cause of the amiable Atterbury, he fell under the censure of Walpole, who sent him to the Tower on a charge of treason. This misfortune gave rise to one of the finest instances of friendship and devotion, on the part of his friend Mead, that has ever been recorded for the honour of human nature. Walpole was taken seriously ill, and of course sent for Mead, who at

that time was the most popular physician. The doctor is reported to have addressed the minister thus:—"You are very ill, Sir Robert, and I can cure you; but one condition is indispensable. Dr. Freind has been in prison some months, and my esteem for him is so great that I will not prescribe a single thing for you until he is set at liberty." Walpole hesitated, but Mead was resolute, and at length the tyrant gave way. Freind was released, and Mead, when he paid his first visit of congratulation, took with him a considerable sum of money, the produce of fees he had received from Freind's patients during his incarceration.

Next in order, we must say a few words of Dr. Mead. Richard Mead was born in 1673, at Stepney. Political troubles drove his father, who was rector of the parish, into Holland, where this future ornament of the medical profession was educated, at Utrecht, under Grævius. He continued his studies at Leyden, and, travelling into Italy, took his degree of doctor at Padua. On his arrival in England, where his fame had preceded him, the University of Oxford confirmed his title, and the College of Physicians received him with applause, as did the Royal Society (then but recently established).

He soon became the leading practitioner of the day, and in course of time Physician to George the Second. For more than half a century he attended at St. Thomas's Hospital, and is said to have suggested to Guy the foundation of the hospital known by that name. A more noble, disinterested, and generous man than Mead never lived. His emoluments were very large, and his benevolence and hospitality kept pace with his income. It is stated that no poor applicant ever left his door unrelieved.

"Large was his bounty, and his soul sincere,  
Heaven did a recompense as largely send."

He lived without envy, leaving his many literary labours as monuments of his talent and industry, and after a life of 80 years, died full of honours.

The reign of Queen Anne has been called the Augustan age of literature in England, and was in no less degree looked upon as the great day of medical science. In the former we have to name Swift, Addison, Warburton, Pope, Steele, Parnell, Rowe, Gay, and others; and amongst Physicians—Freind, Mead, Radcliffe, Cheselden, Arbuthnot, Garth, &c., &c.

Radcliffe next comes under notice; he was a man cast in a rougher mould than Mead. John Radcliffe was born at Wakefield, in Yorkshire, in 1650, and educated at Oxford, where he became a Fellow of Lincoln College; after a two years residence he resigned his Fellowship and devoted himself to physic, removed to London, and settled in Bow-street, Covent Garden. He was a man of ready wit, and great conversational powers, with much pleasantry and frankness. In 1686 he was appointed physician to Princess Anne of Denmark, and after the revolution was often consulted by William the Third; the latter on his return from Holland sent for Radcliffe, and shewing him his ankles swollen, and his body emaciated, the doctor brusquely said, "Truly I would not have your Majesty's two legs for your three kingdoms." This sally lost him the king's favour, nevertheless he still prospered, and sat in Parliament for the borough of Buckingham.

In the last illness of Queen Anne, Radcliffe was sent for, but excused his attendance on account of indisposition; the Queen died the next day, and Radcliffe was greatly censured, which is said to have hastened his own death, which took place three months after.

There is a story told of his quarrel with Sir Godfrey Kneller, the celebrated painter. They were next door neighbours, and enjoyed a certain garden in common. Kneller complained that Radcliffe took no care that the door leading into this garden was kept properly shut, and sent a snappish message to the doctor, that if he were not more mindful he would shut up the door and keep the key. Radcliffe's answer was, "Tell Sir Godfrey Kneller he may do what he likes with the door provided he does not paint it." Kneller retorted to this sarcasm, "Tell the doctor I will take anything from him except his physic."

I cannot find that Radcliffe ever published any work; but at his death he left the munificent sum of £40,000 to the University of Oxford for the formation of a public library of medical and philosophical science, and a further considerable sum to provide for an annual augmentation of books and instruments. Garth, in allusion to this bequest, remarked that for Radcliffe to found a library was as if an Eunuch should establish a Seraglio.

Samuel Garth was among the celebrities of this time: The correspondent of Bolingbroke, the friend of Swift and Addison, and the patron of Pope, he must have possessed great merit to have reached such a position; he was born of a good family in Yorkshire, the date of his birth I have been unable to discover, but he was admitted a Fellow of the College of Physicians in 1693.

Garth was an active and zealous Whig, and consequently familiarly known to all the great men of that party; his orthodoxy was questioned, but it was the fashion of the times to be a free thinker. Pope apostrophises him in his second pastoral—

"Accept O! Garth the muses early lays,  
That adds the wreath of ivy to thy bays."

And again, in conjunction with Arbuthnot, in "the Farewell to London,"

"Farewell Arbuthnot's raillery  
On every learned sot,  
And Garth the best good christian he  
Although he knows it not."

Pope's favourite physician was Dr. John Arbuthnot, and never was grateful affection better bestowed. He was the son of an Episcopal clergyman in Scotland, born in 1675, and went through a course of academical studies at Aberdeen, where he also took the degree of Doctor of Physic.

On his arrival in London he supported himself as a teacher of mathematics, of which he was a great proficient, and became known to the world of letters by his examination of "Dr. Woodward's Account of the Deluge," by an able treatise on the "Advantages of Mathematical Learning," and the first book of the memoirs of "Martinius Scriblerus" has also been attributed to him. An accident introduced him to Prince George of Denmark, and led the way to his appointment of Physician to Queen Anne, and he retained the favour of the Court until the death of the Queen, when, being more than suspected of holding Jacobite proclivities, he was compelled to leave his quarters in St. James's Palace, and he retired to a small house in Dover-street.

Pope dedicated to him the prologue to his satires, and thus gracefully mentions him:—

"Friend to my life (which did not you prolong),  
The world had wanted many an idle song."

The concluding stanzas are so full of tenderness that I venture to give them:—

"Oh! friend, may each domestic bliss be thine,  
Be no unpleasing melancholy mine,  
Me, let the tender office long engage  
To rock the cradle of reposing age,  
With lenient arts extend a mother's breath,  
Make languor smile and smooth the bed of death.  
On, cares like these, if length of days attend,  
May Heaven, to bless those days, preserve my friend,  
Preserve him social, cheerful, and serene,  
And just as rich as when he served a Queen."

For some time before his death he suffered from asthma and dropsy, and bore his affliction with characteristic fortitude and resignation. He died in 1734, leaving a son, who was one of Pope's executors, and two daughters.

Next to the illustrious Scotchman whom we have just dismissed comes a very worthy native of the Emerald Isle—Hans Sloane, the son of Alexander Sloane, the head of a colony of Scotchmen, who, in the reign of James I., settled in the north of Ireland. Hans was born at Killileagh, in the year 1660. He very early showed a liking for Natural History, and on his arrival in London attended lectures on Anatomy, Botany, and their kindred sciences, and formed a close intimacy with Boyle and Ray. After four years study he visited Paris and Montpellier, in which places he took his Degrees in Medicine. In 1684 he returned to London and commenced practice, being

now a Fellow of the Royal Society and of the College of Physicians. On the appointment of the Duke of Albermarle to the government of Jamaica he accompanied that nobleman, and thus acquired a rich addition to his Museum of Natural History.

A curious illustration of the observant mind of Sir H. Sloane is furnished by the fact of his having noticed that the natives of the West Indian Islands, who eat much of the green fat of the turtle, perspired a yellow oil; the explanation being that the true green fat of the turtle is a green-coloured cellular tissue enclosing a yellow oil, which passes through the system undigested. The anatomical data on which this statement is advanced have been, at a comparatively recent period, verified by actual experiments performed by the late Dr. Pereira, assisted by our much esteemed former President, Dr. Daldy. It occurred to my mind that this fact in dietetics might present a lesson of caution to an audience peculiarly exposed, as citizens of London, to the temptation of eating a material, which, however appetising, is incapable of healthy assimilation.

We have now reached the period at which legitimate medicine was established in this country; and as my discourse has already exceeded the assigned limits, it remains only to record our solemn tribute of the affectionate remembrance we all entertain towards those members of our society whose faces we shall so sadly miss in our next sessional meetings. Constituted as our cherished society is, as a friendly gathering of kindred spirits, actuated by mutual necessities, meeting as brothers, knowing no rivalry but the desire to impart, each to other, the results of our matured experience, it is with more than ordinary grief that we bow submissively to all-wise dispensation when Providence sees fit to lessen our numbers by death.

But it is not we alone who have sustained a loss. The name of Barlow will live for ages to come as the type of the scientific physician of the nineteenth century. A man of cultivated intellect, of elegant mind and blameless life, of calm judgment and exalted feeling, I look upon his death as nothing less than a calamity to the whole medical profession.

Too soon, alas! after him, we were shocked by the almost sudden removal of the accomplished and genial Jeaffreson, endeared to his brethren by those solid endowments which mark and govern the high minded practitioner and amiable gentleman—no less than to the public by those qualities inherent in a warm, kindly, and generous nature. And, what then shall we say of our dear friend, Henry Blankarne, so recently carried to his rest. Who can ever forget his pure and simple nature, his spotless life, and those endearing virtues which attached him so closely to those whose privilege it was to enjoy his friendship—one of Nature's gentlemen, considerate and delicate of the feelings of others, generous to the poor at the sacrifice of his valuable life, ready at all times and seasons to give his time for the promotion of any, and every benevolent scheme in connexion with our calling; we shall long mourn over the good old man. As I stood by and saw him committed to the ground but the other day, my mind reverted to the other honoured members I have mentioned, and I felt that one and all had realized and fulfilled to the letter the following monition of Bacon:—

"I hold every man a debtor to his profession, from the which as men of course do seek to receive countenance and profit, so ought they of duty to endeavour themselves, by way of amends, to be a help and ornament thereunto."

I now beg permission to draw the curtain. I have laid before you, with but little skill, some rapid sketches of our illustrious predecessors. I have shown how worthily they have fulfilled their mission; and, having approached the advent of that great man, to whose memory we dedicate this evening, I make my bow and retire, first thanking you for the attention you have accorded to my dull recital. I pause now, because I can add nothing to your knowledge of the character and labours of John Hunter. His patience under such difficulties as would have destroyed an ordinary worker, his sublime indifference to personal comfort and advantage when the interest of that science which he

so well loved was in question—all these facts are "familiar to your minds as household words."

But, whilst we honour him by these periodical meetings, and by the discussion of subjects which formed the happiness of his life, it is only in the great museum, founded by his energy, that the grandeur of his character can be felt.

In that hallowed path, in which he delighted to tread, the mantle of his genius has fallen upon one who, with a kindred love, aided by the marvellous instinct of his own original mind, still follows out the investigations of the great author; adding each day something to the knowledge which went before, and still turning over some new page of the book of Nature, wherein the finger of God has written, in characters hitherto undeciphered, fresh evidences of His glorious infinity. Under the auspices of our honorary member, Professor Owen, we gaze and admire.

## Lectures.

### THE GULSTONIAN LECTURES.

By Dr. REGINALD SOUTHEY.

#### ABSTRACT OF LECTURE II.

DELIVERED MARCH 1, 1867.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

##### THE NATURE AND AFFINITIES OF TUBERCLE.

*How the different opinions entertained upon the nature of tubercle have become indoctrinated. Heteroplastic and hyperplastic growths. Two methods of Cytogenesis. Tubercle a heterologous growth, and hence closely allied to Cancer. Tubercle a lymphomatous tumour. The nature of lymphomatous tumours. Ductless glands the physiological type of these tumours; example of the simplest single form like a solitary follicle of the intestine; example of the compound form like an ordinary lymph gland. Two distinct sub-classes of tumours developed upon this pattern: the one being hyperplastic enlargements of normally pre-existing structures, the other being new growths or heteroplastic formations. The leukemic lymphoma; the typhoid lymphoma; the scrofuloid lymphoma; lympho-sarcoma; their several inter-relationships and their kinship to tubercle. Scrofula. The scrofulous diathesis. The scrofulous lymphoma.*

In commencing his second lecture, Dr. Southey proceeded to show in what way the different opinions of the Humoral school became indoctrinated. Sylvius de la Boc in 1695 stated that tubercle arose from certain glands in the lungs, which resembled those of the neck and mesentery, and hence the lymphatic doctrine of tubercle, as entertained by many eminent men. The same explanation is still offered by Humoralists of the present day. Dr. Rindfleisch in 1862, and Professor Virchow in 1865, and many others whom Dr. Southey quotes, and whose peculiar observations and opinions he presented to his auditors. He considered that this dyscratic blood theory usually ended by premising capillary obstruction by means of the aplastic fibriniform material thus introduced into the circulation, and by deriving tubercle directly from capillary embolism—by finding degeneration of the coats of arteries in people who had died of tuberculous diseases; thus, Henlé considered that the first wrong step was a defect in the capillary circulation—a coagulation of the blood in the vessels. Lebert and Peacock had noticed in several cases that aneurismal dilatation of the arteries accompanied tubercular developments. Bouchut observed the presence of granulations, not merely in the substance of the pia mater, but especially along the walls of the larger vessels of the brain in children who had died of tubercular meningitis. Dr. Rindfleisch found that the walls of the blood-vessels were not only studded up to

their finest twigs with grey tubercle, but that the developments in question were still visible as spindle-shaped varicosities upon the capillaries themselves. His investigations led him to attribute the first step of the tubercle growth to a hyperplastic increase in the finely granular substance of the middle coat of the vessels—accompanying this increase the nuclei multiplied became more spherical, and the structureless adventitia was bulged out before them—the protoplasm thickened into a cell wall around the nuclei, and thus the larger tubercle cells were found.

Not denying the possibility of this, Dr. Southey still observed that it must be remembered that evidence exists in favour of the more frequent origin of tubercle from the connective sheaths of the blood vessels, besides which their purely vegetative functions militate strongly against the probability of their substance ever being the point of departure of a new growth. He does not dispute the fact that tuberculosis is preceded by a distinct blood error—indeed, he would allow of capillary embolism as no uncommon accident in its course; but then, he says, the question at issue still remains just where it was, we shall not have advanced our knowledge of the pathological process one iota by these speculations, and must inevitably come back to the first and only actual evidence of definite error—the tubercle growth, which as yet has only been distinctly traced developing itself out of the connective or some correlative tissue.

He then explained the two terms which he used—heteroplastic and hyperplastic growths, as necessary to a thorough discussion and comprehension of the nature and affinities of tubercle, after which he remarked:—

“Cytogenesis in cell development appears to be conducted upon two principal plans, and I attribute the highest physiological importance to their distinct comprehension. The one is termed the homologous or divisional mode, the other the heterologous or endogenous.

“In cells which multiply by the homologous or divisional plan, the parent cell wall, endoplast and periplast together, enters into the composition of the walls of the several child cells. The separation of these from each other is of secondary moment; it is effected in two different ways: First, by fission, a dipping in of the parent wall about the divided nuclei, and by union or fusion of opposite sides; and, second, by gemmation or budding out of the cell wall, and pinching off of the out-growth.

“The point of importance is this, that although growth to almost any extent can take place in this way, no higher, no different development, is thus attained, the ultimate products are *fac similes* of their parents. Hyperplasia or increase in quantity of like forms only is thus attained. Examples will present themselves at once to the minds of all who hear me. Cartilage, bone, connective tissue, cells all increase thus; but in cells which multiply upon the heterologous or endogenous plan, the external wall, the periplast of the parent cell, forms no part of the external wall of the brood cells; here, too, the child or brood cells are probably separated from each other in two different ways: First, by the dipping in of the endoplast about the parent cell contents, and the segmentation of these thereby; and secondly, by the development of new endo and periplasts about the divided nuclei.

“Yet a few words more. Unicellular organisms, says Huxley, experience only external change of shape. All other plants and animals experience a morphological change of endoplast and periplast. The endoplast grows and divides, but undergoes neither chemical or structural metamorphosis. The periplast, however, experiences both chemical and structural change: the chemical changes, which are of two kinds, organic and inorganic, aim at the maintenance of nutrition and at solidification, while the structural changes, and fibrillation are rather directed to the cohesion of parts elementally distinct.

“The periplast of Huxley is the intercellular substance of Virchow, and just as growth or development takes place only by means of cells, so the metamorphosis or differentiation into tissue is effected chiefly by the product excretion or peculiar appurtenance of each particular cell, its peri-

plast or external layer. This is that which is plastic or shapeable, the rest point the object aimed at, the form which confers those attributes on a tissue, through which we are enabled to speak positively as to its character, saying this has the features of elastic fibre, that of bone, another of cartilage or muscle or nerve.

“I do not for a moment pretend that the cells proper with their endoplasts undergo no structural change; they are metamorphosed in the direction of the tissue which they compose; they are the method of its nutrition, the means of its growth, and are capable of functional activity, as cells, for long after they have been considerably modified in shape by flattening and lengthening out in one or more directions. But it is the intercellular substance, the periplast, which, by its capacity for further development, wields them in its larger grasp and relatively higher bent; this it is which, at first always soft, gelatinous, and homogeneous, becomes granular, streaked or fibriform, cleaved or split. These are those parts which, originally separate, fuse together at their edges and confer unity, coherence, and permanency to formed tissues.”

He then proceeded to notice the affinity or kinship, as he calls it, of tubercle with other morbid growths.

He had shown tubercle to be a heterologous growth proceeding by endogenous development out of connective tissue cells, but never reaching a connective tissue element again. They appropriate nutriment to themselves and grow, but they are short-lived, conceived in haste, and having no power of endurance. It is in this very matter, he said, that we perceive a close relationship between tubercle and cancer, and as Mr. Paget has shown in his pathological lectures, there are several other features in which they strongly resemble each other. These he specified at large, though he said cancer is allowed to be a graver heterologous error than tubercle, the latter having little or no power of maintaining itself, whereas the former is capable of low organisation, blood-vessels developing in it and extending freely throughout its substance.

Next, he reviewed that group of cognate growths which Virchow has classified together under the heading of lymphatic tumours, all which possess certain features in common. After accurately defining those features, he continued:—

“This, then, is the type which we must hold before our eyes. The tumours developed upon this plan fall into two clearly distinct sub-classes. The one comprehends the hyperplastic enlargements of structures which pre-existed in a normal state; the other includes the new or heteroplastic formations. In both cases the component elements proceed out of connective tissue, and in themselves are identical or highly similar; but the importance attaching to them is, of course, much greater when they occur in parts which ought properly to present nothing of their kind.”

In the one sub-class we have the leukæmic lymphoma, the typhoid lymphoma, the scrofuloid lymphoma, lymphosarcoma, scrofulous glands; and, in the other sub-class, tubercle of mau, the perlsucht, or parresyge, or morbus gallicus, the pearl distemper of animals.

Most of those different abnormal formations contained in the first sub-class were separately described by the lecturer. He specified their individual characteristics, the points in which they resemble or differ from each other, their sites of predilection, their appearances, and a variety of other peculiarities, reserving scrofula as a much more important type of morbid affection for his next lecture.

ERRATA.—In Lecture I. of “The Gulstonian,” published last week, for “orastina” read “blastema;” for “pusora” read “presence;” and for “embryoral” read “embryonal.”

THE Ladies' Sanitary Association have issued an advertisement offering a premium of £100 for the best essay on “Vaccination,” its actual value and attendant dangers. The essayists are requested to write without reserve; consequently, with so alluring a prize, and with such an injunction, the field will doubtless be full of competitors from all parts of the kingdom.

## CLINICAL LECTURE

ON A CASE OF SCIATICA, ATTENDED WITH  
MOTOR PARALYSIS.

By C. HANDFIELD JONES, M.B. Cantab., F.R.S.

PHYSICIAN TO ST. MARY'S HOSPITAL.

GENTLEMEN,—Some of you may remember the patient whose case I am about to detail to you. We shall find in it I think interesting matter of consideration.

D. G., æt. 60, a hale strong looking elderly man, a horse-keeper, was admitted November 2nd, 1866. He stated that he generally had enjoyed good health, and his calm and steady manner convinced me immediately that there was no reason to be on our guard against any (so-called) hysterical exaggeration of his sufferings. Three weeks ago while at work he was taken with severe pain in the right hip, and down the leg to the ankle; he did not "rick" or strain himself at all; the attack was instantaneous, he turned faint, sick, and giddy, every nerve trembled. After half an hour he recovered a little, and was taken home to bed. When attacked he did not fall, nor lose consciousness, but was obliged to lie down. His urine at this time was not thick or red. Since his illness he has had difficulty in urining, he is ten minutes about passing a quantity which before he would have passed in one. At present the pain persists, and is continual, is rather worse at night. Heat makes the pain much worse, if he was to put the limb near the fire it would drive him into fits. The movements of the hip-joint are quite free. Has not the least power of moving the limb as he lies in bed, can barely stir the toes a very little. The limb is somewhat wasted. Bowels not at all costive. The foregoing notes were taken immediately after his admission; he was ordered olei morrh  $\mathfrak{z}$ i. *bis die*, and to have lig. opii sedat.  $\mathfrak{M}$ . x. injected subcutaneously between the tuber ischii and the great trochanter. 3rd. Says the pain disappeared immediately after the injection, but came on again about midnight, *i.e.* in eight hours, nearly as bad as ever, and continued till nine a.m., when it diminished and allowed him to sleep well. Feels now a little cramping continuous pain all down the back of the left thigh, leg, and foot, increased by pressure on any part. Can move his leg a little more. The muscles on the anterior aspect of thigh act with the interrupted current, those on the posterior are more inert. Those on the anterior and posterior aspects of leg act fairly well; appetite good, urine acid, sp. gr. 1015, not albuminous. No disorder produced by the opiate. To be faradised daily, and to have the injection every night. 4th. Passed a very good night. 5th. Can flex his leg now very well at knee, and can flex the thigh on the pelvis to a considerable extent; "all the difficulty" he refers to the space between the tuberosity of the ischium, and the great trochanter. Bowels not open; olei crotonis  $\mathfrak{M}$ . half; extr. coloc. co. gr. iij in pil. h.n. 7th. I sible to stand, can raise his limb to right angles with his trunk when lying on his bed. 10th. Is out of bed and dressed, can walk about, but his leg gives way at times with him from weakness. He is almost free from pain, did not need any injection last night. Says that he has not experienced any benefit lately from the faradisation, but that the first few times it was applied it made him feel as if the circulation was increased in his leg, as if everything was set free, and the movement restored. On applying the current myself, I observed that the muscles at the back of the thigh and leg responded but languidly to the stimulus; no better effect is produced with the primary than with the secondary current. Continue faradisation—strychnia gr. 1-20; tinctura ferri muriatis  $\mathfrak{M}$  xv.; spt. æth. chlor.  $\mathfrak{M}$  x.; aq.  $\mathfrak{z}$ i. *ter die*. 12th. Doing well; says he has noticed from the first that he makes perceptible advance every other day. 14th. Can walk much better; complains of a continual aching pain all down thigh, leg, and foot; it is not, however, severe enough to make him wish to have the subcutaneous injection repeated. In half an hour after taking the medicine, he experiences spasmodic pain in the upper part of his abdomen, attended with a sense of cold-

ness there, and considerable trembling all over his body; these symptoms last three hours, then gradually subside, but recur after the next dose. He felt nothing of them before he began to take this medicine. Pulse soft, 80; appetite good. Potass. iodidi gr. i.; ammon. carb. gr. iv.; tinct. cinchon. flavæ  $\mathfrak{z}$ i.; tinct. nucis vomicæ  $\mathfrak{M}$  vi.; dec. cinchon.  $\mathfrak{z}$ i. *ter die*. 17th. All pain has ceased. This medicine strengthens him; agrees wonderfully well. The other "stagnated everything," made him very weak and trembling. 22nd. Has walked about the ward to-day for three hours and twenty-five minutes before he felt tired; does not feel the least pain in the limb, only a little sense of weakness just behind the great trochanter, but it is very trifling. Passes his urine quite freely now. Is going out. On being questioned as to what he thought had done him most good, he replied, "that the opiate injection quelled the pain, but the faradisation set all the circulation free, and gave him more power over the limb from its first application."

Let us remark now in this case:—1st. The *suddenness and severity* of the invasion of the disorder. So marked was this, that at first I could hardly avoid entertaining the idea that mischief had occurred in the cranial or spinal nervous centres. Though it is certainly unusual, hemiplegia from cerebral lesion is sometimes confined to the lower extremity. Andral mentions twelve such cases among a set of seventy-five. Had I not been aware how complete the loss of motor power may be in neuralgic affections, the resemblance of the patient's condition to that now alluded to would have impressed me still more unfavourably, and might have led to a wrong diagnosis. The presence and persistency, however, of the pain, as well as its peculiar situation, were sufficiently distinctive to remove speedily any doubt on this head. Abrupt commencement of disorder, at least as far as consciousness is concerned, is a feature not at all uncommon in various kinds of functional nervous derangement. Attacks of epilepsy, of angina pectoris, of asthma, and of epileptiform neuralgia, commence often quite suddenly. It seems as if a molecular change went on in the tissue, which did not interfere with its function until it reached a certain point, but that passed, normal action became impossible. So a wrought iron axle goes on slowly reverting from its fibrous condition to the natural crystalline texture of the metal, and then, when the change has advanced sufficiently, snaps asunder under a strain not at all greater than it had often borne before. The *severity* of the "retentissement" of the nervous system at the outset was very remarkable, especially as the patient was of strong and tolerant constitution, not a weakly and excitable female. Such general commotion is certainly very unusual, unless the superior nervous centres have suffered a considerable shock. You would naturally be reminded, had you been called to this patient when he was first attacked, of ingravescent apoplexy, though the absence of pain in the head and of increasing stupor would soon show that you had not to deal with so formidable an event. The next point for remark is the *locality* of the pain, which was felt all down the back part of the limb as far as the heel, but not at all in its front. How are we to explain this, seeing that a considerable portion of the sciatic nerve makes its way to and is distributed on the forepart of the leg and foot? I do not know that we can account for this at all satisfactorily, any more than we can for the general liability of all nerves to experience, when neuralgically affected, especial suffering at the point where they issue from internal cavities and become superficial. Although Romberg asserts that in sciatica, as in other cases, "the pain is perceived according to the law of eccentricity in the terminal points of the cutaneous nerves of the sciatic," yet I can by no means think that this is exclusively the case. That much of the suffering in sciatica is felt in the main nervous cord or its subdivisions, and not in their cutaneous terminations, cannot, I think, be questioned. This seems to me just as certain as that when I strike my funny bone I feel a peculiar agony in the ulnar nerve just where it has received the blow. No doubt the law of eccentricity is true, but it

is also true that pain is referred very frequently to various points in the track of a nerve trunk.

Next, what shall we say as to the *cause* of the disease in our patient. The previous history tells us nothing more than that the symptoms set in in the midst of his ordinary health, and we found nothing on examination to explain to us the reason of their appearance. Observation of the "juvantia" comes to our help, and if it does not tell us accurately what was the pathological motor, enables us at least to exclude several which have attained a classic celebrity. Thus there can be no question that constipation, neuritis, reflex irritation, gout, rheumatism, and syphilis, were not essentially concerned in the causation of the disease. We had little to do in the way of purging, and still less in administering remedies for any of the above-named diathetic conditions. No remote cause of irritation was discovered, and of course none removed. Inflammation would not have subsided under the treatment employed. It would, doubtless, be more satisfactory if I could demonstrate to you the actual cause which had been in operation, if I could prove the connexion of the malady with some recognized morbid influence. This I am unable to do; but I can remind you of an occurrence which appears to me to have a good deal of analogy with the case before us. A man is quite in his usual health, and all at once is so prostrated by influenza that he is obliged to lay up forthwith. As Sir Thomas Watson states, "the debility coming on at the very outset of the complaint is one of its most singular phenomena, taking place in some cases almost instantly, and in a much greater degree than would seem proportioned to the other symptoms of the malady which it thus ushers in." Now, debility and pain are certainly closely allied conditions of nervous disorder, and, seeing that influenza may occur sporadically, there seems to me nothing unreasonable in believing this man to have been smitten by some modification of the same cause as that which produces epidemic catarrh. Do not think that I would have you make too free with such assumptions as the one I have now ventured on. On the contrary, I pray you to be very reserved in having recourse to them, and never to do so until you have satisfied yourselves, by careful observation, of the non-existence of other more demonstrable causes of disease. At the same time I think it a matter of absolute certainty that morbid miasms do exist, more or less similar to the causes of cholera, malarious disease, and influenza, which operate not infrequently as exciters of a great variety of nervous affections. You have just seen a girl with heart disease under my care, who for six or seven days had severe pain setting in about six A.M., and lasting till ten A.M. It affected the left side of the abdomen, and was attended with moderate diarrhoea. Bismuth and soda in mist. mucilage *ter die*, and opiate enemata at bed-time, had no effect, but the disorder yielded to five grains of quinine at six and ten P.M. This seems to have been a neuralgia of the descending colon, with serous effusion, like the lachrymation which occurs in facial neuralgia. The patient had never been exposed to malaria, as far as we could discover. Last August, a lady not subject to nervous affections, though weakly, while residing in a very healthy rural district, was taken one day with great restlessness, sense of debility, and such disorder of the head that her mind seemed to be failing her. Wine was beneficial, and with quinine she speedily got well. Disorders such as I have now alluded to are, I think, especially apt to prevail during and after cholera epidemics. The whole subject of the influence of imponderable agents on the body is one of great interest and importance. I have adverted to this point chiefly for the purpose of impressing upon you my conviction that in all instances of this kind—and they are common enough—our treatment must be simply counteractive, and not eliminative. If a poison has been imbibed, it is not one that we can remove; all our concern must be to neutralize its effects. This was what we aimed at in treating our patient. We found his limb in severe pain, and we lulled the suffering by opium; we found it palsied, and we stimulated it by faradisation. These means continued for

some time were not mere palliatives; they actually availed by themselves, in no mean degree, to the cure of the morbid state. But they would not have prospered thus, you may be assured, had the symptoms depended on neuritis, or any toxic condition of the blood. In short, the pathological situation was simply this—that the *vis nervosa* of the sciatic nerve, or its tertiary centre, had been deranged by some temporarily acting cause, and the business of therapy was simply to recreate and restore.

Next let me advert to one point which should always guide you materially in forming a prognosis. I mean the length of time which has elapsed since the invasion of the disease. In his lecture on epilepsy, Trousseau uses the aphorism—"A maladie chronique il faut un traitement chronique." Almost always you will find it so. If our patient, instead of being ill three weeks, had been ill three years, assuredly I should not have cured him in a fortnight. Many a disease fails of being cured, not from any defect in the doctor's skill, but because either he is not persevering enough, or the sick man is not patient and confiding enough. The difficulty of curing a disease is much more proportionate to its duration than to its severity.

The *dysuria* which our patient experienced was undoubtedly not dependent on any enlargement of the prostate, or any other structural alteration, seeing that it speedily disappeared under the same treatment which cured the sciatica. How shall we account for it? There are two views which may be taken. One, that the detrusor urinæ was affected in the same way as the muscles of the palsied limb were; the other, that its paralysis was of reflex causation, just as when a neuralgia of the ophthalmic or infra-orbital nerve causes ptosis, mydriasis, or palsy of some of the muscles of the globe of the eye. This latter seems to me much the more probable view, especially as the vesical muscles were not faradised, nor in any way subjected to special treatment.

The last point for observation in the special history of the case before us, is the *injurious effect of strychnia*. The dose prescribed was quite an ordinary one—such as many weakly females take without inconvenience, and there is no reason to suppose that any mistake had been made in dispensing the medicine. His condition appeared to me especially appropriate for strychnia, on account of the paralytic state of the leg muscles. Instead, however, of imparting to their motor nerves tone and vigour, the drug seems to have affected his solar plexus injuriously, which is the more curious, because in some instances it certainly acts very beneficially on the same centres. Here we have an example of one of the chief causes why medicine never can be an exact science—*viz.*, because the bodily frames with which it deals are so very often dissimilar in their vital susceptibilities, in the way they are affected by different remedial agents. You give antimony to one violently delirious fever patient; it calms his brain and saves his life. You treat another in the same way, and are obliged to discontinue the medication speedily, because it prostrates the heart's action. To one sufferer opium is a "divinum remedium;" to another apparently in a like state it is the reverse. One patient bears mercury well, to another it is an utter poison. These uncertainties in the action of our remedies should not make us medical sceptics, but rather more averse to routine and alive to the exigencies of each individual.

And now for one or two general observations suggested by the history, (1) observe the *paralytic character of neuralgia*. The idea first suggested by pain is that of sensibility being aroused and excited, as one eminent writer says, "it is morbid exalted sensation." Experience has led me to look upon it as rather the reverse, and for the following reasons:—(a) It is very often associated with actual numbness, the two conditions appearing to pass into each other. (b) It is often most plainly brought on by circumstances which depress the nervous power, and is ward off by those of an opposite kind. (c) It is very frequently attended with motor paralysis, the muscular nerves bound up in the same trunk as the affected sensory, losing, as they did in our patient, the faculty of conveying the impulses of

volition. (2) *Pain is palsying.*—This was exemplified in our patient by the incomplete paralysis of the bladder, and instances more or less similar are not unfrequent. An elderly lady who was recently under my care with severe neuralgia of the fifth nerve, found that her face was notably drawn to the opposite side during the attacks; she had to use her hand to replace it. Dr. Latham gives three instances in which intense pain destroyed life in the way of asthma. In one the pain was caused by lead colic, in a second by gall stones, in a third by polypus uteri. In all the heart's action seems to have been gradually arrested by the pain. In angina pectoris, when it proves fatal, the heart's action in all probability is arrested by the thoracic pang. The above proposition is included in the larger one of which I have spoken to you in the systematic lectures, viz.—that any kind of irritation operating through an afferent nerve upon a nervous centre, may more or less completely paralyse the motor nerves proceeding from it. (3) Consider the possibility of nerve disorder coming on, as in this instance, suddenly and severely in some other more vital part. Can any one affirm that the solar, or cardiac plexus, nay, even the brain itself, might not have been similarly affected, and if they were, might not the sufferer be brought thereby into a state of exceeding peril? This is no fanciful suggestion, I have known a man die in a very short space of time after what appeared to be his first attack of severe pain in the region of the heart. Andral records a case of intermittent coma, the attacks commencing with vomiting and violent pain of head, which resisted repeated bleeding and leeching, but yielded to quinine, and thus, was evidenced to be a neurosis. In fact, I believe that nervous centres suffer from the causes of neuralgia very much as nerves themselves do, and I have found in a recent paper by Griesinger some important evidence to the same effect.

### TRAUMATIC CEREBRO-SPINAL ARACHNITIS.

By P. C. LITTLE, F.R.C.S.I., &c.

In continuation of my remarks upon the pathology and treatment of cerebro-spinal arachnitis, published in your valuable journal of July 4th, 1866, I beg to contribute a case of traumatic origin which I recently treated.

January 12th. H. D., a gentleman aged 27, plethoric, short-set, and muscular, was suffering much from a rigid and painful condition of the muscles of the neck; a sudden twitching of those of the extremities; inability to rotate, or bend the head without much agony; pain in the back; oppression of breathing; weakness of limbs; headache; "a feeling as if his skull were opening in two;" vertigo; nervousness; fear of impending trouble; confusion of thought; scattering of vision; chilliness; sleeplessness; loss of appetite; sickness of stomach; occasional vomiting; thirst, and confinement of bowels.

His countenance appeared flushed, and anxious-looking; eyes staring; conjunctivæ injected; pupils slightly dilated, and scarcely sensitive to alternations of light; tongue clean; skin hot and moist; pulse 100, full and nervous; heart's action strong and irregular. The head and neck were curved backwards, and only moveable with intense pain. The posterior and lateral muscles of the neck felt tense and hard in tonic spasm. There were evident congestion and swelling about the spinous process of the fifth cervical vertebra, and firm pressure upon either side of it showed great tenderness. The respirations (eighteen per minute) were difficult; inspiration prolonged and audible; expiration the reverse.

The patient had always enjoyed good health up to his present illness, for which he could assign no cause. On my asking him if he could account for the pain in the back, he recollected to have injured himself in a trial of strength, a fortnight ago, in this manner:—With a quick and power-

ful effort he attempted to lift a heavy weight, when he sprained his spine, so much as to be unable to stand erect for a quarter of an hour afterwards. During this interval his head reeled, stomach turned, and he grew faint. He has not been well since, and has lately become so ill that he believes he is "now in for a heavy fever." I prescribed an active aperient of calomel, rhubarb, and jalap to be administered; six leeches to be at once applied over the tender region of the spine; warm poultices afterwards; low diet; no stimulants.

13th. The leeching was followed by the most satisfactory results as regards the head symptoms, only giddiness and transient pains remaining. He slept pretty well throughout the night; his spirits are improved; the bowels had been freely moved; the pulse 88, more tranquil; the features more composed and cheerful; the stiff and painful condition of the muscles persists, but is less troublesome; the neck allows of slight motion.

I then put the patient upon a short course of mercury with James' powder, merely to touch the gums, which was effected in four days. At the end of that period the muscular spasm and rigidity had ceased, but the headache and vertigo continued. A blister to the spine over the leech-bites, so completely removed these symptoms that the patient was enabled to resume his avocation in about a fortnight from the beginning of the treatment.

This case appears to be of considerable surgical interest. It is an example of cerebro-spinal meningitis, induced by accident. In this it differs from most recorded cases which have been attributed to epidemic, tubercular, or idiopathic origin. The chief grounds of my diagnosis here were the following:—

1. Opisthotonos of cervical spine.
2. Tonic spasm of muscles of neck.
3. Twitching of muscles generally.
4. Spinal tenderness.
5. Cerebral and sympathetic disturbance.
6. Irregularity of respiration.
7. History of case.

In my previously reported cases, the foregoing conditions existed in a more marked degree. Thus the muscular spasm and twitching, confusion of thought, fear of impending danger, and nervousness in the present case, were in the former intensified into convulsions and unconsciousness. Here too, the history of the case was all important in determining the exact locality of the primary lesion—an element in the diagnosis, I deem, essential to the proper treatment.

The pathological views of this disease which I ventured to publish in your issue mentioned, appear to be well-founded; and afford a basis of explanation for many of the sympathetic phenomena, relied upon by some recent observers, as pathognomonic of cerebro-spinal arachnitis.

The treatment was, indeed, pleasing in its results. As noted, it consisted in local depletion, gentle mercurial influence, and counter irritation. And here, as in former cases, I was struck with the good effects of depletion from the original seat of lesion, and convinced of the great value of an early discovery of the source from which so much distress sprung.

### ON THE TREATMENT OF DELIRIUM TREMENS BY INDIAN HEMP.

By HENRY J. TYBRELL, F.R.C.S.I., M.R.I.A., &c.,  
SURGEON TO JERVIS-STREET HOSPITAL.

MR. J. K., æt. 40, was admitted into Jervis-street Hospital on the 15th of January last.

Upon examination I found him in a very excited, nervous condition; his pulse 90, very weak and compressible, pupils dilated, tongue covered with a white creamy fur, stomach very irritable, bowels confined, urine scanty and high-coloured—s. g. 1020, skin cool but sweating; although he had no sleep for the last three nights, still he was quite

rational, and gave me the history of his case (which in this country is a very interesting and unusual one) with great accuracy and minuteness. He said he was not an habitual drunkard, and remains as long as eighteen months without tasting any kind of spirit, but that when the desire for drink comes on he is unable to resist it. Some years ago, to avoid taking any, he commenced to use opium, and soon he required as much as four ounces of the tincture daily, to keep up the excitement which was requisite to enable him to pursue his profession as a newspaper editor. At no time did the opium produce a soporific effect. As the opium was undermining his constitution he gave it up about a year ago, and was a strict temperance man until about a month before he came to hospital, but during the last month he consumed a quart of brandy daily. He stated that he had had delirium tremens twice, and that on each occasion the Indian hemp cured him, and that if I wrote to Dr. White, of Downpatrick, under whose care he had been, I would find he was speaking the truth.

As the use of opium was out of the question in the present case, I determined to give the capsicum treatment a trial, and accordingly I ordered two boluses, each containing 30 grs. of capsicum—one to be given every third hour. His stomach rejected the first, the second he did not vomit; they did not give any relief, as on the next day, the 16th, he was much worse in every respect, had no sleep, and his mind was evidently affected. I ordered him 3 draughts, each containing ℥ 20 of the tincture of cannabis indica, one to be taken every third hour. He had the first at four P.M., after the second he became very excited; at eleven P.M. he got the third, and at one A.M. he fell into a deep sleep which lasted about four hours.

When I saw him at ten A.M. on the 17th, he was quite a different man; the nervous excitement was gone; he expressed himself as quite well, but very weak and hungry. During the day he drank two pints of strong beef tea, and in the evening he took another draught, as he was afraid he would not sleep without it.

He remained in hospital two days longer to recruit his health, and left on the 20th quite well. As the treatment by the Indian hemp was so satisfactory, I wrote to Dr. White to test the truth of Mr. K.'s statement, and he kindly informed me that he treated Mr. K. on two occasions with the Indian hemp, and that the effect was marvellous. The dose he gave was forty drops every hour and a-half, and that he was obliged to increase it to eighty drops before sleep was produced—together he used in the first attack one ounce, and in the second a little more of the tincture.

Whether there was a difference in the strength of the tincture, or that the attack for which I treated him was only beginning, it is remarkable that 60 ℥ was only required.

I am not aware that the use of Indian hemp has been adopted in delirium tremens, at least I do not find it mentioned in the books I have consulted; and I certainly would not have prescribed it, had not the patient mentioned its use to me; and although opium-eating is very uncommon in this country, at least in hospital patients, still it is of great importance to have a medicine which may be used instead of it, when that drug is unsuited from idiosyncrasy or any other cause.

## Hospital Report.

### THE LONDON HOSPITAL.

CASE OF LACERATION OF SKIN AND CELLULAR TISSUE IN FRONT OF PATELLA, FOLLOWED BY SUPPURATION FIRST AROUND, AND SUBSEQUENTLY WITHIN THE KNEE-JOINT; AMPUTATION.

(Under the care of Mr. CURLING, F.R.S.)

Reported by Mr. JAMES ADAMS.

THOMAS Cox, aged 25, an unhealthy-looking man, was admitted on January 26th, with a laceration about three

inches in length in front of left patella, which was caused by a fall from a cart-wheel on the previous evening. Immediately after the accident he went to a practitioner in the neighbourhood, who put in several sutures, and told him that it would soon be well. At the time of admission the edges of the wound were covered by a whitish slough, and surrounded by a dusky red margin. He was placed in bed, and a bread poultice was applied. On the following day there was a good deal of swelling around the joint; his appetite was very bad; pulse 100. Ordered wine ℥x., and a poultice of charcoal, as the edges of the wound were sloughy and the discharge unhealthy.

During the next eight days suppuration went on all around the joint; two free incisions were made, and the matter escaped freely; but he did not improve constitutionally, having very little appetite, and the pulse being continually about 100. After a few days more he became much weaker, and the tongue became dry and brown. On examining the knee with the finger, a rough edge of bone could be distinctly felt on the inner side of the joint. As there could now be no doubt that the joint was implicated, and the man's general health failing, it was determined to amputate, which was done on February 14th by Mr. Maunder.

The patient was very ill during the operation, but has improved steadily since; the stump is healing, and he can eat and drink well, pulse remaining steady at 70.

On examining the interior of the joint, the cartilage covering the condyles and patella was found to be removed in several places, and everywhere rendered soft, and could very easily be detached from the bone. The synovial membrane was everywhere highly injected, soft, thickened, and gelatinous. There was also a long sinus running up the front of the thigh under the muscles.

Mr. Curling in some clinical remarks on this case, noticed the rare circumstance of a suppurating wound external to the knee making its way into the articulation. He had treated many cases of such injuries without the joint suffering, being always careful to make free incisions for the ready escape of matter.

A very similar case occurred amongst Mr. Hutchinson's patients some weeks back, the patient having a lacerated wound above the knee, died from phlegmonous erysipelas, and on examining the joint the cartilage was found eroded in several places.

## Foreign Medical Literature.

### A CONTRIBUTION TO THE THEORY OF TUMOURS OF THE BRONCHIAL GLANDS IN THE ADULT.

By Dr. RAGNAR BRUZELIUS.

Translated from the *Nygga* for June, 1866, Vol. xxviii, p. 217.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

THE form of disease, for which I here claim attention, has no distinctly elaborated or complete pathology. The records of its cases have always been poor, and even the extensive medical literature of latter years has not supplied any abundant contributions to the same. Thus Fonsagrives\* in 1861, in his *Mémoire sur l'engorgement des ganglions bronchiques chez l'adulte*, could not collect and bring forward more than nine cases, with the aid of which he nevertheless sought to establish the symptomatology of the disease. Had he been better acquainted with the labours of foreign writers he might indeed have somewhat increased this number, particularly as among others Dr. Cohn† a couple of years ago published some observations of

\* Archives générales de Médecine, 1861, vol. ii., p. 678.

† Beitrag zur Lehre der Bronchialdrüsen-Erkrankungen. Zeitschrift für klinische Medicin von Günsburg, 1859, p. 376.

the kind; but even if our literature be searched with the greatest care, it will not afford any rich harvest of such cases. Most manuals of pathology touch upon this form of disease in a very transient manner; in some, even among the better and more recent, it is scarcely mentioned. The rarity of the disease, its great importance in a diagnostic and prognostic point of view, and the scantiness of the information to be had by consulting our literature, have led me to believe that an account of the following unusual case, with the addition of a few remarks, will not be entirely devoid of interest:—

Johanna Jansson, aged 32, a maid-servant, was admitted into the Seraphim Hospital on the 8th of June, 1864. She stated that her parents had died of diseases of the nature of which she was not aware, and that of four brothers and sisters two had died at an early age, but two still lived and enjoyed good health. She herself had not had any illness except an attack of ague many (14) years ago, and one nine years later of inflammation of the right eye, which had destroyed the sight of the organ and had left a staphyloma behind it. Menstruation had not commenced until she was in her eighteenth year, but it had subsequently been normal. She had since enjoyed good health until Christmas, 1863, when she began to suffer from a gradually increasing pain and tenderness in the epigastrium, whence the pain extended upwards to the chest and outwards to the back. The tenderness was aggravated by taking food; vomiting, partly of food, partly of viscid mucus and clear, acid water supervened, but the vomited matter had never contained blood or "coffee grounds sediment." The appetite was gone; the patient's strength was diminishing, and she herself was very much emaciated.

For these symptoms, which as no tumour could be discovered in the epigastrium, and in consideration of her age, gave reason to suspect the existence of an ulcer of the stomach, she was treated in the hospital with the ordinary remedies with considerable relief. At the end of a couple of months other symptoms set in, which demanded more attention. Thus she began to be frequently troubled with an obstinate dry cough, upon which particularly violent asthmatic attacks soon supervened. They came on without any assignable cause at different intervals (three or four days or more), and lasted from some hours to some days; she had never before suffered from any thoracic affection.

When she was transferred, in the beginning of October, to the clinical division, examination afforded the following results:—

She was considerably emaciated, had a pale yellow complexion, and a cachectic appearance. The chest did not exhibit any deformity, but the left half of it seemed to rise on inspiration rather more than the right. Inspiration, which usually took place with a certain effort, was prolonged, and was sometimes audible even at a distance, accompanied with a peculiar, sibilant, laryngeal sound. On percussion nothing abnormal could be discovered. On auscultation, or the contrary, it was found that the respiratory murmur over the upper part of the right lung was weaker than in the lower part, and in the other lung, and was attended with a peculiar, tracheal like, "coarsely sonorous" sound. Both the inspiratory and the expiratory murmurs were prolonged over both lungs, and were almost everywhere accompanied with piping and sonorous sounds, but no physical signs of solidification were met with. The pectoral fremitus, everywhere weak, did not present any difference in any corresponding part of the chest. The præcordial dulness was of normal extent, and in the usual situation, but the cardiac impulse was felt only as a slight blow against the thoracic wall in the fourth and fifth intercostal spaces; the sounds of the heart were weak, but without any accessory sound. The pulse gave 80 strokes in the minute, was small and even, and perfectly contemporaneous in both radial arteries. The expectoration was scanty, and of a catarrhal nature; on repeated examination with the microscope it was never found to contain any elastic tissue from the lung. The voice was rather croupy and weak, but with an effort the patient could speak aloud and distinctly. On examination with the laryngoscope nothing abnormal

was observed. She complained almost constantly of dyspnoea; this was, however, tolerable between the asthmatic attacks. At night she was sometimes troubled with perspiration. In the epigastrium, which was rather tender on pressure, no tumour was observed, but there was a certain resistance on the right side in the left lobe of the liver. The examination of the liver and spleen did not reveal anything morbid in these organs, nor did the urine present any abnormality. The appetite was tolerably good, the tongue clean, and the bowels were regular.

Her state improved somewhat for a couple of weeks; the attacks of cough and dyspnoea ceased, as did the vomiting, on which account, although very weak, she perseveringly requested to be dismissed, which was done on the 15th October. After a few days she again begged to be taken into hospital. The day after her dismissal she had got a violent asthmatic attack, which still continued when she presented herself anew at the hospital. The dyspnoea and cyanosis were then so severe that suffocation seemed every moment to be imminent. She was taken in; suitable treatment was adopted, and the attack soon subsided.

As to the *diagnosis*, it was, as is evident from the foregoing history, surrounded with difficulties. Certain of the physical signs were but slightly marked, others varied considerably in intensity. Repeated investigations were required to determine them to be such as they are above reported. I endeavoured, however, in the following manner to come to a conclusion as to the nature of the disease:—

The prolonged, often noisy, inspiration and expiration, combined with the difficulty with which the respiration in general is carried on, point to some obstruction to the passage of the air through the organs of respiration. The patient's power of speaking loudly and clearly, even though with some effort, shows that the larynx is not essentially affected, on which point, moreover, the laryngoscope is capable of supplying perfect certainty. On the other hand, the constant feebleness of respiration over the upper part of the right lung, compared with the clear sound on percussion in the same place, is a proof that the obstruction must affect principally the right bronchus, but that the part of the lung just mentioned nevertheless contains air. Some constriction of the larger air passages must therefore exist, and if we take into account also the violent asthmatic attacks which occur without any assignable cause, and cannot be dependent upon an emphysema, nor upon an aggravated catarrh, it becomes probable that some tumour exercises pressure partly on the larger bronchi, and partly on the nerves of the respiratory organs.

Having in this manner made the diagnosis of a tumour causing pressure on the thorax, it remained to answer the second question—of what nature that tumour was. An aneurism may certainly produce such symptoms. I, however, thought myself justified in excluding it, as neither by percussion nor auscultation did I discover any signs indicative of such a lesion, nor did the state of the pulse yield any support to such an assumption. It consequently appeared to me to be most probable that the bronchial glands were the seat of some morbid process, by which they were increased in size, so as to be able to exercise a pressure sufficient to produce the existing symptoms. In such a case a cancerous or so-called tubercular process would most readily suggest itself. Cancer I thought unlikely, chiefly on account of the patient's age (only 32 years), and the absence of any sign of such a disease in other organs; for so long as the gastric symptoms were so undefined as they were in the commencement, I must acknowledge that I did not suspect that they depended on cancer of the stomach, which, nevertheless, during the course of the disease, became more evident.

So-called tuberculosis of the bronchial glands therefore remained as the most probable condition, though this is a name under which morbid processes differing from one another, at least in an anatomico-pathological point of view, have been grouped together. Independent miliary tuberculosis in the bronchial glands, without similar deposition in the lungs, occurs in children, and is said to be met with also in adults. The description of these latter cases is,

however, in general not so detailed and distinct as to remove all doubt as to the nature of the disease. It may consequently be asked how far an independent military tuberculosis in the bronchial glands has been actually observed in adults. I at least have not succeeded in finding any case on record which unquestionably bears the stamp of it. In our patient, of course, we could not with full certainty exclude tuberculosis in the lungs, but on the other hand it was evident from the physical examination that, if it were present, it had caused neither any considerable condensation nor cavernous formation. This circumstance led me also to suppose that the enlargement of the bronchial glands was produced rather by a simple hyperplastic process than by actual tuberculosis.

As to the further course of the disease, a few short statements will suffice:

After her readmission into hospital, she remained there under treatment for many months, and until her death. The symptoms from the respiratory organs remained, varying in intensity, but the dyspnoea gradually increased, and only during short intervals did she feel something better. In the month of February she was attacked with fresh inflammation in the eye which had before been affected, ending in suppuration and atrophy of the bulb. During her stay in the hospital the abdominal symptoms underwent no inconsiderable change. Thus the resistance formerly noted in the epigastrium was gradually developed into a considerable tumour, situated near the left edge of the liver, which became at last as large as an egg, was easily felt, uneven, and knobby, tender on pressure, and somewhat moveable. Notwithstanding this, the intensity of the other gastric symptoms diminished; the vomiting recurred, only at longer intervals; the appetite was certainly not good, yet it had not altogether failed, and to the very last the patient daily used a tolerably fair share of food. No decided sign of pyloric constriction was ever observed, and the vomited matters never contained blood or any other "suspicious" substance. Her state, meanwhile, became more and more miserable, her strength diminished, the emaciation progressed, and during the last eight days a considerable pleuritic effusion took place on the right side, which terminated her sufferings on the 27th of March, 1865.

At the post-mortem examination, which was made by Dr. Odmansson, the following was noted:—

Body considerably emaciated. Cadaveric rigidity in all the large joints. The fat in the subcutaneous connective tissue has for the most part disappeared; what remains of it is of a brownish-yellow colour. The muscles are flaccid and pale.

The skull is long but narrow. Its bones are of ordinary thickness, the dura mater is rather congested. In the anterior part of the superior longitudinal sinus a dry fibrinous coagulum, more than an inch in thickness, loosely adhering to the wall, mostly decolourised, with incipient softening in the centre, is met with. In the posterior part of the same cavity, as well as in the transverse sinus, are loose sanguineous coagula. The arachnoid and pia mater are here and there, between the convolutions, infiltrated with clear fluid in small quantity. All parts of both the cerebrum and the cerebellum are exsanguinous. The cerebral substance is moderately firm.

The right pleura contains a large quantity of an almost clear fluid, tinged with green. The lung is compressed, and is pushed backwards and inwards. Both the pulmonary and the parietal pleura are invested with a thin, in general easily separable, false membrane. Each is connected with the other by adhesions, which, unusually delicate, almost resembling a spider's web, extend through the fluid. In the left pleura a less quantity of a similar fluid is found. On the surface of the right lung, in the false membrane, a small number (ten or twelve) of rounded nodules, varying in size from that of a millet to that of a pea, consisting of a homogeneous, whitish yellow tissue, are seen. The serous investment of the left lung in general exhibits some thickening. The compressed right lung contains some air throughout, except in the postero-in-

ferior part. It is exsanguinous, rather highly coloured. The bronchial mucous membrane is pale, the tubes on pressure yield a slightly purulent fluid. The left lung contains a moderate amount of blood, and air everywhere except in the postero-inferior part. This part is flaccid, carnified. The state of its air tubes is the same as that of those on the right side. The mucous membrane of the larynx and of the upper half of the trachea is pale, and covered with mucus. The glandular openings in the latter place are enlarged. In the lower half of the trachea and in the principal bronchial tubes the mucous membrane is thickened and congested. In the middle and posterior part of the former an opening, surrounded with swollen edges, appears in the wall—this opening is two centimètres in length and half a centimètre in breadth, and leads to a cavity nearly as large as a walnut, bounded by decomposing, cheese-like walls. A smaller perforation of the same nature is met with precisely at the bifurcation. A bundle of enlarged lymphatic glands, in a state of caseous metamorphosis, here and there coloured black, surrounds the whole posterior half of the lower third of the trachea. Some of these glands, in process of breaking up, constitute the boundary of the above-mentioned cavities. Both principal bronchi, especially the right one, are imbedded in altered glands. The right bronchus is, near its entrance into the lung, rather compressed, and has an elliptical bore.

The heart is everywhere intimately adherent to the pericardium. The medium of connection between them is congested connective tissue, forming a layer of unequal strength at different parts of the heart; this is strongest over the left ventricle. Both in this newly-formed tissue and on the parietal layer is found a number of rounded or oval nodules, in general varying from the size of a pea to that of a filbert, sometimes a little smaller or larger, closely connected with surrounding parts. Of these the smaller exhibit an even, shining, tolerably transparent surface of section, with a small yellowish spot in the middle or nearer to the periphery; the larger, on the other hand, show a drier section verging upon yellow. All have a firm consistence, but the larger vary somewhat in this respect. They are met with in the greatest number over the left ventricle. On the upper part of the latter, near the septum, appears a stratum, one and a half centimètres in breadth, between the two laminae of the pericardium, entirely composed of such a mass. This mass is not defined towards the muscular structure, but muscular fasciculi are seen to run in and lose themselves in it. Equally large masses are met with between the pericardium and the lower part of the pulmonary artery, between it and the right auricle. Around the heart, particularly its base, lies a number of enlarged lymphatic glands of the same nature as the bronchial glands above described. Between some of these and the tumour exists (seen microscopically) a considerable similarity. At the base of the heart they lie here and there close upon one another, separated only by a thin layer of connective tissue.

The right auricle contains some thin dark blood. The right ventricle, as well as the left side of the heart, contains some small coagula of blood. The length of the left ventricle, calculated from the middle of the attachment of the right aortic valve, is about seven centimètres (about 2 $\frac{5}{8}$ "); the thickness of the wall near the septum is from twelve to thirteen millimètres (about half an inch). The muscular structure of the heart is flaccid, pale, with a yellowish brown shade of colour. In the anterior lobe of the mitral valve are a couple of yellowish-white sclerotic spots. The valves are otherwise healthy.

The peritoneal cavity contains more than three pints of a clear fluid with a greenish tinge. The transverse and the descending colon are in the left curvature attached to one another by an old firm adhesion of about three inches in length.

The liver is pushed downwards, is free from adhesion to the surrounding parts, it is rather small, somewhat congested, flaccid, of moderate consistence. In the middle of the right lobe some firm calcareous concretions, of irregular

shape, are met with deep in the parenchyma. The gall-bladder, attached superiorly by a long string of connective tissue to the stomach, contains a small quantity of thin, green bile.

The spleen is small, everywhere closely attached to the surrounding parts. Its capsule is considerably thickened, inferiorly it is of a white colour and cartilaginous nature. Its substance is pale, firm. The Malpighian bodies are indistinct.

The capsules of the kidneys are firmly attached. Their surface is even, but slightly granulated. The cortical substance is rather thin. This, as well as the pyramids, with the exception of the papillæ themselves, which are pale, contains a moderate amount of blood. The finer division of the cortical substance is distinct; the substance, with the exception of small yellowish grey spots on the septa fasciculorum is of ordinary transparency, its consistence is particularly firm.

The pyloric portion of the stomach is hard to the touch. The calibre of the pylorus is much constricted, allowing only the little finger to pass. The walls here, as in the antrum pylori, are enormously thickened, measuring on section in many places an inch or upwards. The thickening affects all the constituent tissues, but principally the sub-mucous, which exhibits a gelatinous, shining, transparent surface of section, traversed by fine, white septa, which, from the outer part of the sub-mucous tissue, radiate towards the inner surface of the stomach. The mucous membrane exhibits in the greater part of this portion superficial loss of substance. In the parts surrounding the seat of thickening too, small superficial defects are met with. Directly over the lesser curvature, and intimately adherent to the wall of the stomach, lie a couple of tumours as large as walnuts, presenting the same appearance as the sub-mucous tissue described above. The omental attachment is considerably thickened.

Some of the upper lumbar glands are enlarged; the surface of section is caseous, here and there it is loose.

The mucous membrane of both the small and large intestines exhibits spots of tolerably intense venous injection, but is otherwise unchanged.

The ovaries are rather small, round, with particularly uneven surface, and present everywhere on section a shining homogeneous appearance. Near the surface are some few corpora nigra. There is nothing else to remark upon.

In order to render this report of the post-mortem examination more complete, I shall here append the result arrived at by Dr. Odmansson, after an accurate microscopical examination, as to the nature of the tumours met with in this case (*Förhandlingar vid Svenska Lakaresällskapets sammankomster ar, 1866, p. 6*). "The tumours in the stomach and omentum represented a typical alveolar or colloid cancer. The change in the lymphatic glands indicated, according to his view, the second and third stages of lymphatic glandular scrofula, as both the macroscopical and histological state of these organs negated the assumption of any properly malignant swelling, such as cancer or sarcoma; as no miliary tuberculosis was met with elsewhere, nor could the changes in the lymphatic glands be shown to have proceeded from miliary tubercles; and, as the change, though limited to a certain group of lymphatic glands, those situated within the thorax, nevertheless here occurred so extensively, and in so high a degree. The tumours in the pericarditic and pleural new formations of connective tissue depended on a proliferation of small round cells of the appearance of lymph-corpuscles proceeding from the connective tissue bodies. In the somewhat larger tumours only the outermost zone exhibited this condition, while in other parts the newly-formed cells had already undergone fatty degeneration and breaking up. Where the tumours penetrated into the muscular structure of the heart the same small indifferent cells appeared among the muscular filaments. A tumour at least macroscopically similar is described by many writers under the name of 'tubercular pericarditis,' 'tubercularisation of pericarditic false membranes,' &c. In our case the affection

would undoubtedly have been looked upon by these writers as tubercular. If we entertain the views of the North German school, or those of Virchow, doubts must occur as to the assumption of the tubercular nature of these tumours. No actual miliary tubercles are met with; the tumours have evidently grown by an uniform proliferation in their vicinity, and moreover miliary tubercles are not found in other organs. It is well known that Virchow, in the last number of his *Onchologie*, very accurately describes syphilomata. According to his view our tumours ought rather to be referred to this last-named form. In addition to reasons just quoted, the appearance and transient nature of the cells are in favour of this opinion, as well as the circumstance that the tumours have been developed in the midst of the new formation of connective tissue, which circumstance is characteristic of syphilomata, though not solely or always belonging to them. We may, however, on the other hand, observe that the assumption of the syphilitic nature of the tumours is venturesome, as there are no other symptoms of syphilis, and the patient's antecedents do not justify such an opinion, as syphilitic tumours in internal organs cannot yet be looked upon as sufficiently known, and as the enlargement of a tubercle merely from the juxtaposition of miliary tubercles cannot be considered to be fully proved. Moreover, we have in lymphatic glands a process which, if not identical with tuberculosis, is nevertheless closely allied thereto."

We thus find, on post-mortem examination, not merely the tumours diagnosed during life, in the stomach and bronchial glands, but also a third form, in the heart, the proper nature of which cannot with full certainty be determined. Notwithstanding that these tumours in the heart were very considerable, both in number and size, this organ never during life presented any symptoms whence we could infer it to be the seat of such a pathological process. The cardiac sounds were indeed, although physiological (pure), weak, as was the heart's impulse, but this phenomenon could very well be explained in connexion with the state of weakness in the whole system, which was in this case evident. As no other signs of a defective action of the heart were observed, we cannot be surprised that this change in that organ was not diagnosed. The perforation of the bronchi, which was produced by the ulcerative process in the glands, was not distinguished by any prominent symptoms (for example, more considerable hæmoptysis), though the latterly somewhat increased expectoration of a purulent, sometimes slightly blood-coloured secretion, ought to be attributed to the spread of the ulceration to the air-tubes.

To this account of the case, and of our line of diagnosis, it will not be unsuitable to add, for the sake of comparison, a short review of the more important symptoms, which have been observed by others in similar cases (of bronchial glandular tumours).
